This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

English

ENGLISH MECHANIC

AND

WORLD OF SCIENCE.

WITH WHICH ARE INCORPORATED

"THE MECHANIC," "SCIENTIFIC OPINION," AND "THE BRITISH & FOREIGN MECHANIC."

ILLUSTRATED WITH NUMEROUS PRACTICAL ENGRAVINGS.

VOLUME XXXVIII.

PUBLISHED (FOR THE PROPRIETOR) BY E. J. KIBBLEWHITE,
AT THE
OFFICE: 31, TAVISTOCK STREET, COVENT GARDEN, LONDON, W.C.
SOLD BY ALL BOOKSELLERS AND NEWSAGENTS IN THE KINGDOM.

1884.

THE NEW YORK
PUBLIC LIBRARY
1[illegible]7
ASTOR, LENOX AND
TILDEN FOUNDATIONS.
R 1899 L

Printed by BRADLEY and COMPANY,
12, 13, and 14, Fetter Lane, London, E.C.

INDEX TO VOL. XXXVIII. ENGLISH MECHANIC.

ABERRATION, forms of lenses for least, 85
Abbott's leaflets, 519
Absorbent cotton wool, 312, 329
Accidents: railway, Brinnington junction, 219
  Carlisle, 175
  Lockerbie, 40
  Lofthouse, 175
  Perth, 175
  Retford, 219
  Waterloo colliery and Portsmouth, 266
Achromatic object-glass, 258, 485
Achromatism, 128
Acids, fatty, 471
Acoustics, 327, 346
Action, pianoforte, 432
Adding machine, Neary's, 32
Adulteration, bread, 521
Advertisement, another quack, 125
Advertisements: dynamos and, in ours, 428
  wall, 284
Afterglow, 365, 385, 408, 427, 556
Age of moon, ascertaining, 534, 558
Aged persons, sleeping with, 500, 522, 543
Agriculture, 95
Air: brake, 290, 328
  germs in the, 254
  moisture in, 22
  pump, 19
Alarum: electric striking clock and, 392
  fire, 543
  self-acting boiler feed and, 465
Albumen process, lantern transparencies in, 381, 403
Albuminoids of milk, 199
Alchemy and modern science, 382, 406, 421
Alcohol: and coffee in Brazil, 338
  extracting from oil, 521
Alcoholometry, 500
Alkalimetry, reagents for, 471
Alloys, aluminium, 121, 362
Alphonsus, dark spots in, 321, 339, 385
Altimeter, Wells', 218, 264, 300
Altitudes, 271
Alum, soda and, 545
Aluminium: and aluminium alloys, 121, 362, 388, 393
  coating of, 373
  plate reactions, 15
  polishing, 391
  the manufacture of, 431, 471, 473
Amateur wind instrument making, 152, 246, 342, 389, 453, 538
Amber and bone bending, 178
American: association for the advancement of science, 58
  English and Fairlie locos. in New Zealand, 158
  locomotive practice, 419
  locomotives, 200
  organ, 373, 433, 475, 503, 543, 563
  railways, 474
  trial of an Otto gas engine, 527
Ammonia: 307
  and alcohol as sources of motive power, 326
Ammonium salts, 199
Analyses of pyrites, 566
Analysis: blowpipe, lessons in, 26
  of coal tar, 503, 528
  of drugs and vegetable substances, 150
  of lime, 494
  of oil-cake, 506, 528
  spectrum, 263
Analytical theories, 272, 287
Anæsthetics, Paul Bert on, 504
Ancient lights, 503, 523, 524, 544
Aneroid barometer, 469
Angle, dihedral, 414
Angles of lathe tools, 281
Angular velocity, 19
Aniline: 199
  colours, extracting, 394, 471
  ink, 418
Animal: electricity, galvanic and, 80
  intelligence, 11
Ankles, weak, 200
Annealing and case-hardening, 511
Anthropology, address in, 101
Anthropometric committee, report of, 84
Antimonial lead, 524, 544
Antimony, lead and, 250
Antiquity of man, 85
Aperture: and focal length of telescopes, 300
  on the relation of, to power in micro. object-glasses, 367, 410, 470
Apertures of the principal telescopes, 446
Apology, a too ample, 263
Apparatus: for estimating carbon in steels, 260
  for optical experiments, 85
Apprentice: and housework, 176
  overtime, 176, 182
  wages, 90
Aquarium cement, 44
Aqueous vapour, production of electricity by condensation of, 568
Archimedes: 61, 86, 105, 148
  clefts near, 105
Architectural: drawing, 502
  photography, 43
Arg. 2600, 289, 320
Argelander's star charts, 300
Argyll, duke of, on geology, 207
Arietis (41), 263, 320
Aristarchus, 448
Arithmetical, 93
Armagh observatory, 514
Armature: 503
  Gramme, 522
Armatures for dynamos, patent, 543
Artificial production of minerals, 227
Ash of coal, 20
Assaying, 477
Astronomical: 12, 37, 86, 105, 201, 247
  diagrams, 494
  notes: 78, 165, 276, 358, 449, 464, 550
  observations at high altitudes, 124
  Society, Liverpool, and practical work, 86, 125, 239
  transits, focal adjustment of, 347
  work, 494
Astronomy: specialism in, 301, 323
  the progress of in 1883, 375
Atlantic: cables, working speed of, 267
  geological age of the North, 124
Atmospheric pressure, 544
Atomic: theory, 69
  weight of tellurium, 562
  weights, 269
Attraction: by sound, 561
  of the Earth by Mass, 170, 217
Audiphone, the, 44, 69
Auriga, 322
Auroræ, 239
Author, an, who did wrong when he did write, 514
Automatic: musical instruments, 473
  vacuum brake, 218
Auxiliary power for tricycles, 306
Axle of electrical plate machine, 456, 478
BACILLUS of phthisis, 383
Back-centre, combined wheel and lever, 5
Baillie-Hamilton's improvements in reed-organs, 213
Baked potatoes, 262
Balance: prize essay on the compensation, 17, 63
  staffs, drilling up, 203
  torsion, 201
Balance-gear of omnicycle, 391, 411
Ball, Prof., on the measurement of the Sun's distance, 106
Balls: golf, 201
  small steel, 564
Balsam, chloroform, 411
Banjo, 312, 391, 412, 524
Bankruptcy Act, new, 65, 81, 284
Bark, cinchona, 468
Barlow's wheel, 523
Barometer: aneroid, 469
  height of, 94, 113
  low, 36, 90, 125
  natural, 494
Barrel organ, 393, 481
Bartolozzi, 456
Bassoon, 271
Bath: electric, 543
  heater, 458, 479, 502, 522, 543
  toning, 203, 226
Batteries: bottle, 437, 456
  galvanic, improvements in, 233
  in signal boxes, 137
  primary, cost of, 295
  secondary, 104
  — as empties, 170
  storage, and electric currents, 227, 218, 418, 433, 522, 537
Battery: bell, an inexpensive, 223
  bichromate, crystals in, 95
  Bunsen, 289, 310, 327, 347
  chloride, 524
  chromate of zinc, 351
  double-cell bichromate, 523
  "Edco," the new, 379, 457, 503
  for coil, 115
  for continuous work, 137
  for lamps and model boat, 112
  for lighting, 453, 479, 545
  good bichromate, 159
  granule carbon, 21, 134
  Hughes, 480
  Leclanché, 94, 321, 503
  negative plates for, 428
  Ross, 326
  secondary, chemical action in the, 104
  Skrivanow, 493
  small, 432
  thermo-electric, 351
  three-cell, 71, 134, 178, 286
  Wollaston's, 437
  zinc of, 349
Baywood, varnish for, 311, 323, 348
Beam: strength of, 545, 565
  weakened, 392
Beans, preserving kidney, 72
Bearings, 248
Beasts, brakes and, 101
Bed, mushroom, 116
Bedding in and rolling over, 363
Beds: filter, 68
  lathe, 566
Bee-farming in New South Wales, 536
Bee-keeping: 71, 428, 472, 497, 519, 536, 558
  Abbott's leaflets, 519
  modern, 66, 90
Beer in scratch-brushing, 524, 544
Bees: 158, 201
  food for, 394, 433
  parasites on, 159
  spring treatment of, 559
  stings, wasps and, 346
Beeswax, substitute for, 158
Belgian astronomer-royal, resignation of, 300
Bell battery, inexpensive, 223
Bells, electric, 95, 350, 457, 478, 521
Belts: crossed, 350, 372
  working off pulleys, 350, 372, 392, 412 432, 454, 472, 500
Bending: amber and bone, 178
  brass, 372
Bert, M. P., on anæsthetics, 502
Berthelot on explosives, 9, 30, 37
Berthon power-gauge, 155, 175, 192
Bevel, adjustable, 8
Bichromate battery: crystals in, 95
  durability of solution for, 545
  good, 159
Bicycle: making, 197
  painting, 415
  the Otto, 281
Bicycles: and tricycles, 280
  at night, 181
Bill on demand, 430
Billiard balls, staining, 91
Binocular eyepieces, 414, 522
Birt, clefts phi and zeta, 426, 496, 534
Bismarck and the vegetarians, 562
Black: dyeing, 156
  for cement, 545
Bleaching: horsehair, 524
  sponge, 261
Block: handy surface-plate, 37, 67
  system, the, 519
Blow, heavy, and great discouragement, 125
Blower: cheap adapted pyrological hand, 218
  fan, 391
  new pattern hand for blowpipe analysis without valve or spring, 277
Blowpipe: analysis, lessons in, 26
  new pattern handblower for, 277
Blue moons, 449, 469
Boat: lead keel for model, 158
  model electric, 44
Boat detaching contrivance, 409
Boats: paper, 236
  raising, lowering, and securing ships', 5
Boiled onions, 262
Boiler: 182
  corrosion, zinc for preventing, 51
  Engert's steam, 187
  feed and alarm, self-acting, 465
  feed-water, heating, 221
  gas for, 436, 503
  model, 71, 187, 522
  — testing, 326
  plates, punching, 11
  query, 326, 346, 371, 458
  steam, 456
  strength of, 180
  tank, 311, 328
Boilers: incrustation of, use of catechu in preventing, 215
  incrustations in, 393
  prevention of incrustations in, 261, 374
  strength of, 158
Boiling silver to whiten, 347
Boldo, 439
Bone, how one is built, 405
Bonework, inks for, 308
Boot sewing machine, 71

Boring: cylinder, 271
  holes in glass, 522
Boro-glyceride, 22
Bottle batteries, 437, 456
Bottling-wire, straightening fine-gauge, 112
Bourdons, 412
Box: raising lid of iron, 201, 225, 247
  thermometer, 425
Boxwood, seasoning, 268
Brace, small, 21, 43, 69
Bradford's washing machine, 5, 114
Brain, overworked, 349
Brake: air, 290, 328
  automatic vacuum, 218
  history, links in the, 114
  McConnell's steam sledge, 520
  Parker-Smith, 15, 64, 90, 107, 132, 154, 195, 243, 265
  Sanders-Bolitho, 139
  vacuum on L. and N.W.R., 135
  Westinghouse, 339
  — double couplings, 542
Brakes: and beasts, 101
  continuous, 114, 174, 265, 305, 323, 340, 385, 415, 519
  — return, 131, 305
  on the L. and N.W., 179
  vacuum, 271
Brandy, manufactured, 421
Brashear and Bow, to Mr., 243
Brass: 68
  band music, arranging, 116, 179
  bending, 372
  polishing and bending, 306, 312
  soft, 290
Brasswork, lacquering, 411
Brazil, coffee and alcohol in, 338
Brazing: 137, 225
  ends on Muntz metal tubes, 311
  without heat, 456
Bread: adulteration, 521
  unfermented, 543, 564
Break, rapid, 414, 502
Brewing, 289
Brick glaze, 565
Bricks in wall, 393
Bridges, opening railway, 21
Brighton engines, 178
Brine cistern, paint for, 43
Bristol and Exeter express engines, 434, 500
Britain, introduction of Christianity into, 85
Britannia Co.'s new naval lathe, 316
British Association: 103, 123
  address in anthropology, 101
  — chemistry, 82
  — geology, 83
  — mathematics and physics, 81
  — president's, 54
  report of anthropometric committee, 84
Brixham flint implements, 217
Brompton grasping, City guilds and, 469
Bronze, imitating, 522
Bronzing: iron, new method of, 199
  mounts, 564
Broth, kettle, 662
Brush dynamo, 225, 227, 288, 309, 327, 432, 474, 500
Brussels observatory, the new, 383
Bucket, history of a, 466
Building: acts, metropolitan, 434
  freehold property and, 201
  not too expensive, 306
  Society, mortgage, 43
  — sale of shares, 65
  — subscriptions to, 225
Buildings, instrument for roughly estimating height of, 218
Bulb, hyacinth, 149
Bunsen: battery, 289, 310, 327, 347
  burner, 288
  cells, E.M.F. and R. of, 362, 567
Bunting, dyeing, 434
Burners: lacquering, 351
  paraffin lamp, 451, 496
  regenerative, 522
Burnisher, 181
Burnishing steel, 391
Butcher's ice room, 350
Butterflies, relaxing, 524
Buttons, manufacture of, 407

CABBAGE, stuffed, 261
Cabinet: making, 12, 158, 246, 307
  tool, 224
Cables: transmission in, 350
  working speed of Atlantic, 267
Caillot's rest, M., 275
Calculation, wheel-teeth, 564
Calculations in mechanics, 521
Caledonian engines, 248, 268, 454
Calico printing, 471
California, 545
Camelopardalis: 148
  stars in, 171, 192
Camera: bellows, leather for, 373
  lucida, on a new, 466
  stereoscopic, 287
Canal, Panama, and the Gulf Stream, 15, 40, 174
Canals, Suez and similar, 155
Cancer in the mouth, 96, 114, 135, 157, 178, 224, 286, 454
Candle making, 157
Canned foods, are they dangerous? 231
Cannon, the, steam engine, considered as motors, 382
Canoe or small sail boat, 224
Caoutchouc noses, 250
Car, spring motor, 253
Carbon in steels, apparatus for estimating, 280
Card, sundial on, 94
Cardboard, attaching fossils to, 26
Carp, German, in U.S., 237
Carpentry, hints on, 119, 185, 196, 253, 358
Carpet, permanganate stains in, 471, 478
Carriage lift, 269
Carrier for lantern slides, improved, 423
Cartridges for Martini-Henri, 95, 113, 135, 156
Case-hardening, annealing and, 511
Casks, spokeshaves for, 20
Cassiopeia, magnitudes of stars in, 494
Cassiopeiæ, gamma, 239, 320
Casting lead, 350, 372
Castings: chilled, 565
  softening malleable, 567
Castor, 426
Casts, plaster, 394
Catalogues, star, 37
Caucasus, tea-planting in the, 75
Cauliflower, cooking, 252
Cavendish, 279, 385
Cell wall, protoplasm and the, 123
Cement: aquarium, 44
  black colour for, 545
  coloured Portland, 566
  for indiarubber slips, 159
  for pavement lights, 434, 456
  iron, 567
Cementing object-glasses, 263, 286, 431
Centimetres, inches v., 469
Central Institution of the City and Guilds Institute, 549
Centre board, 93
Ceti, alpha, 147
Charts, Argelander's star, 300
Cheap lathe, how to make, 163, 210, 245, 257, 265, 285, 305, 316, 372, 377, 390, 443, 487
Cheapest food, 289, 310, 328, 347, 371, 411, 432, 474, 521
Checks upon tramway fares, 201
Chemical: 69, 70, 92, 150, 226, 248, 349
  action in the secondary battery, 103
  action of etching copper, 21
  elements, sunspots and, 103
  experiments in the lantern, 422
  problems, 432, 481, 502, 543
Chemistry in elementary schools, 123
Chess: 23, 47, 74, 98, 118, 140, 162, 185, 205, 229, 252, 274, 292, 314, 332, 352, 375, 397, 417, 439, 461, 483, 505, 526, 547, 568
Chest, misshapen, 226
Chevreul, M., 494
Chicago Astronomical Society, annual report of the, 163
Children sleeping with aged persons, 500, 522, 543
Chimney: flues, 71
  shafts, wrought iron, 70, 92
Chimneys, house, 456, 501
Chimonanthus fragrans, 22
Chinese white: 36, 45, 323
  and glycerine, 338
Chip potatoes, 91
Chisel and chisel-shaped tools, the, 445
Chloroform balsam, 411
Christianity into Britain, introduction of, 85
Chronograph, 308
Chronometer rate, 290
Chronometers, humidity as a cause of variation in, 266
Chuck plugs, 93, 131
Chucking, 285
Chucks: 377
  fitting to Holtzapffel's mandrel-nose, 245
  wooden, 106, 285, 306
Church: draughty, 311, 328, 348
  gas for small, 44
Churchyards, law respecting, 502, 522
Cigarette machine, 45
Cinchona bark, 468
Circles of an equatoreal, reading, 263
Circular: glasses, cutting, 308
  saw, power for, 480
Cistern: 546
  deposit in water, 564
City and Guilds Institute, central institution of, 549
City Guilds and Brompton grasping, 469
Clarionet: 19, 42, 91, 111
  or oboe, 20, 43, 66, 111, 152
  playing, 414
Clark's improved diamond hive, 14, 39, 130
Clayey soil, 413, 433
Cleaning: o.g.'s, 247
  sponge cloths, 477
  stove pipes, 71
Clefts, who discovered the lunar? 545
Clepsydra, or driving clock for small telescopes, 561
Clock: at Washington, new, 125
  chime, making, 65
  driving for small telescopes, 561
  electric, 350, 372, 392
  — and alarum, 392
  grandfather's, 458
  long pendulum case, 250, 271
  to strike by electricity, 457, 501
Clock-case, long pendulum, 250, 271
Clocks to strike by electricity, 457, 501
Clun stone circle, sunrise at the, 469, 514
Coaches, weight of L. and N.W., 544
Coal: ash of, 20
  is the steam-engine a waster of the energy of, 410
Coal-burning locomotives on Midland, 480, 502
Coal-gas: as a labour-saving agent, 490
  Pettenkofer on poisoning by, 235
Coal-tar, analysis of, 506, 523
Coating for iron and steel, protecting, 460
Coffee and alcohol in Brazil, 338
Coil: Ruhm. spark, 349
  induction, 68, 89, 201, 230
Coil: medical, 137, 158, 179, 201, 224, 250, 286, 521, 567
  — street, 346
  resistance, 226
  shocking, regulator for, 524
Coils: 306, 325
  and paraffin paper, 451
  with horseshoe cores, 473
Coin, spurious, 20
Cold, Arctic, 38

THE ENGLISH MECHANIC

AND WORLD OF SCIENCE.

LATHE SCREWS AND MANDREL NOSES.

THE discussion on ornamental lathe screws and mandrel noses carried on in our columns during the last four volumes is at last fairly before the members of the Amateur Mechanical Society, an occasional number of their *Journal* having been issued with the express purpose of submitting the question to the members, who, if they act in their corporate capacity, can at any rate set the fashion so far as amateurs' lathes are concerned. We need not even summarise what has been said in our columns, for the gist of the whole matter, pro. and con., will be found in the first half of the last volume; but for the benefit of readers who are not lathemen, we may say that the question is of a similar character to that practically settled by the Royal Microscopical Society, when it issued what is known as the Society's screw, and also to that which has long agitated the wire-drawing world, which latter will probably be settled by the electricians without the consent, or without so much as "by leave," of the gentlemen who are kind enough to make wire of all sorts of gauges, and call it by numbers which mean one thing here and another there. Thanks to the action of the Royal Microscopical Society, an amateur can now buy a stage of any maker of repute, and know that if at any time he wishes to add to his battery of objectives, he will experience no difficulty in consequence of a difference in the screw-thread. The question is, Whether lathe-makers might not with advantage adopt recognised standard threads for the various parts of their machines (about which, we believe, there is no dispute); and whether 10 threads to the inch is not better than 9·45 (or some number approximating to that), or than 13·09? It will be remembered that on the 11th of October, 1882, the Council of the Amateur Mechanical Society passed some resolutions on the subject, which were afterwards repassed on Jan. 10, 1883, in the following form, recommending—

1. A rate of 10 threads to the inch for the geometric mandrel-nose and back-centre screw.

2. An enlarged cylinder base in place of the present circular groove at the root of the mandrel-nose.

3. A thread of 50°, truncated 7¼ per cent. of its pitch for the mandrel-nose and other fine pitches.

These resolutions were subsequently found to be informal, and it was then determined to submit the question to the members of the Society by issuing an "occasional" number of the *Journal*, which can now be had of Messrs. Trübner, Ludgate-hill, for two shillings. In this number, Dr. Edmunds sets out his views at length in a "Memorandum upon Ornamental Lathe-Screws," and in a paper entitled, "Suggestions for a Standard Mandrel." In the first he states the case quite as fully as is necessary, and gives such information as will enable the members of the Society to decide as to what aliquot screw-threads should be recommended for new geometric lathe apparatus. It must be remembered that in slide-rests the "ornamental screws" have already been superseded by the screw of ten threads to the inch, and the question is now whether it would not be possible to set up a standard series of screw sizes, so that if a screw is removed from one lathe it will fit another of the same size; or, in other words, so that the parts can be kept in stock at the tool-shops, and be obtained at the shortest notice. It is not a question of whether the screws adopted by famous makers are suitable for the work they are called upon to do, but one of convenience to their users, and, if makers would but understand it, of sound business policy. It cannot be argued that screws having 9·45, 13·09, 19·89, 25·71, and 55·11 threads to the inch have any special virtue in the decimal figures, whereas a purchaser does see a very great virtue in a machine all the smaller parts of which he can duplicate at the nearest machinists' tool-shop, and all the screws of which he can either buy or cut by means of an ordinary lathe and a small battery of change wheels. Owners of costly lathes will not agree with Dr. Edmunds that screws having aliquot rates ought to at once supersede those having fractional rates; because, as soon as a series of standards is adopted, the commercial value of the older lathes will be materially reduced, however excellent they may be as tools; but the great majority of amateur workers with the lathe will, undoubtedly, vote for standard sizes, and for screws which can be readily reproduced. Dr. Edmunds, in his "memorandum," proposes that the comb screw tools and mandrel guides should be denoted by numbers indicating the threads per inch; taps and dies by the number, and also by the outside diameter of the threads; and he also suggests that all bolt-heads, nuts, &c., should be made to one or other of the Whitworth standards, and that the number of sizes in use should be as small as practicable. With regard to Dr. Edmunds' suggestions for a standard mandrel, they are as follows:—

1. The face of the mandrel to be made much larger than at present, with a view to minimise the tendency to angular variation in the setting of the chucks.

2. The base of the mandrel-nose to be a true cylinder, palpably larger than the outside of the thread, to which the first part of the chuck-bore will be accurately gauged, so as to minimise the tendency to excentric variation in the position of the chucks.

3. The face and nose of mandrel to be finished as may be, without risk of chipping or fracture, &c.

4. The mandrel to be drilled out, &c.

5. The mandrel-nose to be coned out in front, &c.

6. The mandrel-nose to be screwed with the thread he describes, and at the rate of ten threads to the inch.

Dr. Edmunds proceeds to give the dimensions he would adopt, as we understand him, from experimental models he has made, and concludes with his reasons for asking the council to consider the question with a view to formulate a collective judgment.

At the meeting of the Society at which it was decided to publish an "occasional" number of the *Journal*, the hon. sec., Mr. T. W. Boord, M.P., observed that there were other views worthy of consideration, and it would be necessary to take care that the members were fully informed before being asked to express an opinion. In his capacity as editor of the *Journal*, Mr. Boord has given Dr. Edmunds every encouragement to make his paper as complete and exhaustive as possible; and besides appending some remarks of his own, has called upon two representative amateurs, General G. C. Clarke and Rev. S. B. Burnaby, to state their opinions. As these are printed in the "occasional" number, we may, it is to be hoped, shortly expect to hear the decision of the members of the Society. General Clarke supposes everybody is agreed that if all screws were to be started afresh, it would be desirable that aliquot parts of the inch should be invariably employed in determining their respective pitches, which should bear a fixed proportion to the diameters of the screws, and he agrees with Dr. Edmunds in wishing that in all future apparatus the makers of lathes, &c., should adopt such a standard. General Clarke thinks, however, that, as the lathes and screws in question have been copied, and are in use all over the world, Dr. Edmunds has somewhat exaggerated the supposed defects of those screws, and some of his objections to them appear fanciful rather than practical. He points out, too, that it is only in parts of the lathe that screws have been selected without reference to the particular pitch of each, and that where uniformity is necessary, screws of ten threads to the inch are employed. With reference to the suggestion that if the back-centre screw of 13·09 threads to the inch had been made with ten threads, and the head divided to hundredths, the depth to which the boring-screw had advanced would be accurately known by the number of the turns of the handle, General Clarke points out that it is necessary to withdraw the boring-tool repeatedly to clear away the shavings, and to do that in the readiest manner is to run back the back-centre bodily, and that being done, he asks what becomes of the accurate measurement of the depth of the bore? General Clarke says that for forty years he has not experienced the inconveniences which he is supposed to have suffered. He has comb-tools to match each guide, and that is all he finds necessary; while every screw about his lathe agrees with one or other of the guides, so that they can be easily replaced if broken. The Rev. S. B. Burnaby treats the question in a very different style, for he evidently thinks it "much ado about nothing." He points out that the question was "unanimously" resolved to be put at a meeting of the Amateur Mechanical Society, when two members were present—the mover and seconder of the resolution. Then he proceeds to say that "we shall be asked whether we prefer threads of 13·09 or 19·89 to those of 13 or 20, and so on," and he thinks that a large majority of people will answer, "No, we do not"; in fact, most people will be unable to see the use of asking such a question. If a further question is asked, whether the "people" much care whether the binding or fastening or holding down screws of the apparatus be 36·1 or 36, the answers, he thinks, may vary, some saying "they do care," and others "they don't care." The Rev. S. B. Burnaby thinks that the accident of the loss or breaking of a screw does not occur frequently, and he further thinks that if such screws can be purchased for "a few pence" they will be cheap at the price. He thinks that all troubles under this head would cease if the owner of the lathe would purchase a stock and set of dies, and a few screw tools adapted to his lathe, no matter what terrible decimals are to be found in the rates of its screws. There are no lathe-makers, he says, who make the leading and measuring screws of their apparatus, whether for slide-rest or "ornamental" chucks, other than of aliquot rates. With regard to 9·45 for the nose of the lathe, Mr. Burnaby says there "is not the least difficulty in arranging a set of wheels to cut this thread, any more than in cutting one of nine pitch," and a calculation which would occupy five minutes would last a lifetime. With respect to the proposed new form of mandrel-nose, he says, "no practical man would think of adopting such a concern"; the neck should on no account be of greater diameter than the nose itself; and "any ordinary workman trying to fit chucks to such a mandrel . . . . would simply and totally fail."

The hon. sec., Mr. T. W. Boord, M.P., also replies much to the same effect, but reduces the whole case to the simple question whether, if the back-centre screw of 13·09 threads to the inch were made with ten threads, it would enable the turner to accurately and easily gauge the depth of a hole *drilled with the aid of the back-centre.* He gives practically the same reasons as General Clarke why it would not, explains why he objects to Dr. Edmunds's proposed dimensions for the mandrel-nose, and thinks if the interchangeability of chucks were brought about, it would be of little use. We have thus endeavoured to give an idea of the arguments pro and con., which are set out very fully in the *Journal*, and those interested should carefully study the question as there set out before making a final judgment.

DIMENSIONS AND RESISTANCE OF WIRES.—II.

By John T. Sprague.

15. THE different essential facts as to the conductivity and resistance of the most important metals are given Table I., derived from Mathiessen's measures taken in connection with the preparation of the original ohm. Later determinations differ, and a set by Benoit may be found, p. 112, Vol. IV. of the "Journal of the Society of Telegraphic Engineers"; but Mathiessen's values are generally received, and his well-known care and the means at his disposal justify the retention of his values.

Table I.—Conductivity and Resistance of Metals.

Different figures are given in various books, and the specific gravity and specific resistances are by no means too certainly known; but, as it appears absurd to present a set of values in one table which cannot be made to agree, with the result that the student has no definite starting point, I have calculated the whole of this table from the two values of Cols. VI. and VII. by means of the formulæ § 26. Therefore, should any other values be deemed more accurate, there will be no difficulty in altering the whole range of values, which are physically dependent on each other.

Col. III. is the *specific resistance*, that of 1 cubic centimetre expressed in microhms. By shifting the decimal point 6 places to the left it becomes ohms, and by shifting it 3 places to the right it becomes C G S units: thus copper = 1·652 microhms, ·000001652 ohm, and 1652· C G S units. Microhms are convenient for metals, ohms for liquids, and megohms for dielectrics.

16. The line of carbon is derived from my own experiments, and relates to the artificial carbons, such as are prepared for the Jablochkoff candles and arc lamps. The specific gravity is probably greater in the carbon of incandescent lamps, but it is scarcely possible to measure it, as the adhering film of air prevents its being properly weighed in water. It is probable also that the specific resistance is lower; but to discover this, either the specific gravity must be known, or the diameter, which is equally difficult to measure experimentally.

Correction for Temperature.

17. It is convenient to adjust resistances at the ordinary temperature, 60° Fahr., for which reason, also, the values are given in the formulæ and tables at that point. But it is necessary for many purposes to know the resistance corresponding to a temperature different from that at which observations are made, for temperature plays a very important part in the resistance of wires; in fact, it is difficult to get the same resistance twice for a piece of copper wire, if it is touched, or if the slightest change takes place in the room.

The variation with temperature does not occur equally for each degree, but in a curve. For all ordinary purposes, however, the correction may be taken for each degree Fahr., near about 60° as being—

Copper	as 1 to 1·00215	log.	0·0009327
German silver ..	„ 1·00024	„	0·0003126

and the correction is made by multiplying the decimal portion or the logarithm by the number of degrees (not by the logarithm of the degrees), and multiplying the resistance observed, for higher temperature, and dividing for lower temperature; adding or subtracting, as required, the logarithmic correction to the logarithm of the observed resistance.

Thus, to correct from 60° to 32°, or the freezing point (zero Cent.) is 28° ·00215 × 28 = 1·0602 for copper. The correct figure due to the full curve is 1·0605.

18. It is probable that these figures apply only to moderate heats, and Müller gives the following resistances for high temperatures of certain wires experimented on.

Iron.		Copper.		Platinum.	
0° Centi.	640	0° Centigrade	814	0° Centi grd.	1870
21°	681	21°	864	21°	1986
[illegible] ..	1065	Slightly incandescent ..	2100	Slightly incandescent.	4300
Dark red	329	Carmine red ..	2450	Red hot	4700
Bright red .	3650	[illegible] red	3300	Orange.........	5400
White heat	458	Bright red ...	4700	Light yellow.	6000

On the other hand, carbon as in the incandescent lamp has a resistance, when cold, just about double of that when at full light-giving temperature.

19. Specific *heat*, that is the quantity needed to raise unit weight of any substance 1 degree in temperature, *increases* as the temperature approaches the point of a change of physical state, such as fusion. But Siemens, in the course of his experiments on electric pyrometers, found that the increase of resistance by heat is reduced as

the temperature rises, and that the resistance of a metal may be expressed as

$$R = a\sqrt{T} + \beta T + \gamma$$

R being the resistance, T the absolute temperature (reckoned from absolute zero − 273·7° Cent. or − 470·66° Fahr.), and $a\ \beta\ \gamma$ are coefficients related to the particular metals.

Dimensions of Wires.

(20) For electrical purposes, in addition to the ordinary commercial considerations of weight, length, and strength, we must include electric resistance; so that if we fix upon a definite unit, which includes weight, length, and resistance, all considerations are resolved into mere multiples of that unit.

Then, instead of thinking of wires by their mere diameters, we should take into account their sectional area, which is as the square of the diameter. The most convenient basis of practical measurement is the thousandth of an inch now commonly known as a *mil*. Since wires are round, and the areas of circles increase as the squares of the diameters, we should regard the "mil" as a circular wire, and wires generally, not as single cylinders, but as though they were built up of a series of parallel, unit cylinders. Then by squaring the diameter in "mils" of any wire, we obtain direct its area in circular mils—that is to say, the number of unit wires to which it is equivalent. To make the unit complete, its length must be defined, and the foot is the most convenient measure. But as in electricity we require to include in our unit electric resistance as well as the weight, &c., it is still more convenient and generally useful to make weight, rather than diameter, the basis of the unit, and the most generally useful unit would appear to be a wire 1ft. long, weighing 1 grain. By ascertaining the relation of this, for each metal, to the general circular *mil* foot, every necessary calculation can be readily effected. This relation is given as nearly as present knowledge allows in Cols. VI. and VII. of Table I.

Wire Gauges.

21. Wire is usually bought by Birmingham wire gauge; but no one can tell what the Birmingham wire gauge is, and different dealers will differ two or three sizes, while, in the finer wires, it is a mere chance what will be obtained for any gauge asked for. The subject was taken up by a committee of the Society of Telegraphic Engineers and Electricians, whose report will be found in the *Proceedings* of the Society, Vol. VIII., 1879, p. 476. It appears probable that the B W G originated in the sizes resulting from successive draws from the rod of iron, subsequently adjusted to diameters reducing by 8ths, 16ths, 32nds, and 64ths of an inch, and then by 10ths of the 64ths; but makers varied them to suit their purposes, and it is said employed different gauges for paying the workmen or for buying from those used in selling. The committee suggest a new gauge based upon a logarithmic curve, in which each number is 25 per cent. heavier than the next lower: such a curve permits any unit of weight or diameter to be used, and it is proposed to make No. 0 the starting point, with a diameter of 1 centimetre, or inch ·3937, which approximates the average existing values. The following table will show the differences in the gauges:—Col. I. is that of Stubbs and Holtzapffel; II. is that of Messrs. Wynn, and is employed in Culley's work on "Telegraphy," and generally used by electricians; III. is the theoretical original scale, arrived at by the late C. V. Walker, based on 640ths of the inch, and derived from a gauge supplied by Messrs. R. Johnson and Nephew, the well-known wire drawers, with small corrections to fit it to the theory. Col. IV. is the committee's new scale, based upon Latimer Clark's logarithmic curve, and proposed to be called the B.S.G., or British Standard Gauge. The discrepancies increase in the higher numbers, which have been introduced long after the original gauges were established. The best plan is not to go by gauges at all, but adopt either the measured diameter or the weight of a given length, as is always done upon the large scale by electrical engineers.

Table II.—Wire Gauges in Mils.

15	72·	73·	75·	73·9	36	4·	7·9	—	—

22. A wire is simply *a cylinder occupying a certain measurement of space*. The weight of the cylinder will depend upon the specific gravity of the material which fills the space.

A *cubic inch of water* weighs 252·456 gr., and this multiplied by 12 and by ·7854 gives us the weight of a circular inch-foot of water; and that multiplied by the specific gravity of any metal gives the weight of a circular inch-foot of that metal, and thus the datum for all required calculations. Taking as the basis, copper = 8·9 the sp. gr. of good copper wire, we find that the circular inch-foot weighs 21176·1 grains, and the logarithm of this 4·3258478 by altering the index to −1 (that is to say, dividing by a million, the number of *mils* to the inch) gives us the weight of the unit mil-foot wire, from which all other information can be calculated. This weight, grain ·0211761 is symbolised, for copper, by M in the formula to be used here. From it we obtain 47·22 as the area of the foot-grain wire in mils, symbolised by G, and the square root of this, 6·872, is its diameter.

23. Assuming as correct the resistance of one foot-grain wire given in Table I., we obtain all that is necessary to complete the data—viz. the resistance of the unit foot-grain wire, which I have calculated at 60° and inserted in column IV. of Table III.

Resistance of soft copper

Correction for 28°, 1·0605 .. 0·0255107

Unit resistance at 60°, U. .. −1·3402204 = ·21889

Constants of Unit Wires.

24. Table III. gives the principal constants required for calculations. Those for German silver and brass are for average values, and those of Col. IV. for the grain-foot resistance U ought to be determined for any particular sample if exactness is required. In the case of German silver it may vary 50 per cent., and in that of copper, in proportion to its conductivity.

Formulæ for Wires.

25. As the following formulæ differ in several points from those generally given to attain the same results, it may be explained that this is owing to the definite system of which these form a part. Most other formulæ are single ones, devised each for its own purpose, and often based upon mere actual measures of particular wires, which often vary in quality. Those given here may have no actual superiority over these others, except as forming part of a definite system based upon mathematical truths, and linked especially to the conception of wires, not as each separate entities, but as consisting of collections of unit wires of definite property, thus giving to d^2 an extended meaning, from the mere square of the diameter of single wires to the number of units in all wires.

Symbols Used in the Formulæ.

26. Let the following letters represent the requisite particulars.

W = weight in grains. $W \div 7000$ = weight in pounds.
w = ditto per foot. = $M \times d^2$ or $d^2 \div G$.
M = ditto per mil-foot = $m \times s$ or $1 \div G$ or $U \div u$.
m = ditto ditto of water = ·0023793 Log. −3·3764578.
d = diameter in mils (inch ·001) = square root of d^2.
d^2 = square of diameter = area in circular mils = $w \times G$.
G = area in mils of the grain-foot = $1 \div M$ or $u \div U$
g = ditto ditto of water = 420·29 Log. 2·6235422.
l = length in feet.
s = specific gravity. = $M \div m$ or $U \div (u \times m)$.
R = resistance in ohms at 60° Fahr. $U \times l \div W$.
r = ditto per foot = $R \div l$.
U = ditto ditto of the grain-foot = $r \times w$.
u = ditto ditto of the mil-foot = $U \times G$ or see $\mathcal{R}$.
$\mathcal{R}$ = specific resistance of cub. cent. ohm = $u \times$ 0000016624 Log. −7·2207291. ditto for microhms use index −1·; for C G S units 2.
$\mathcal{R} \times$ reciprocal of these constants gives u.
$s \times m$ gives all the data for weight &c., so that from these two data all requisite information can be calculated.

27. In working out any examples I shall use logarithms, because they are really the simplest of all modes of calculation except the slide-rule, which is, in fact, a logarithm machine. Every one should learn to use them, if only for the sake of extracting square and cube roots which only requires the division of the logarithm by 2 or 3.

The whole system of calculation for wires is really contained in §§ 26; but as it would be too concise for unpractised readers, I will explain in more detail, with examples in my next paper.

PRACTICAL NOTES ON PLUMBING.—LXXIX.*

By P. J. Davies, H.M.A.S.P., &c.

(*Continued from page* 595, *Vol. XXXVII.*)

Rams Without Air Chambers.

NEXT examine Fig. 375. This, another of Blake's rams, is made to work without the use of the air chamber, a plunger, E, being substituted in its stead, which is held down by the springs H H, and the cross-lever J. It will be plain that when the ram is put into action, that as the water rises from the body of the ram into the pipe D and R, that at every pulse which the foot valve C makes, the momentum of the water will be felt upon the bottom of the piston E, and which will cause the piston to jig or rise with a spring at each stroke of the ram. It also follows that the piston E must rise in its cylinder according to the pressure upon its lowe arrest the column of water, the weight of the water in the trunk A will tend to create a partial vacuum; and in proportion to the velocity and weight of the water, so will the diaphragm G move inwards, and so work the lever H, which being jointed at J with the short slotted lever K, will raise the pump piston L, when the effect of the momentum of the water within the trunk is past, so will the weight I bring back the lever H, and with it the diaphragm, and so on alternately, and it will be plain that by this method water may be raised to any height required. This diaphragm arrangement may be made to give an outward thrust instead of an inward action, and may be fixed at B W, Fig. 376.

Rams with Double-Foot Valves.

FIG. 379.

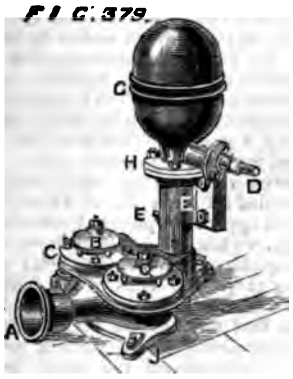

FIG. 380.

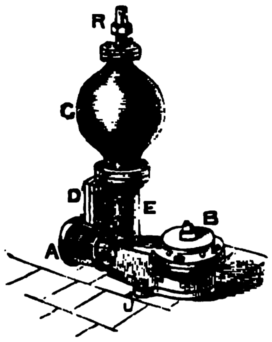

This kind of ram is illustrated at Fig. 379. The parts are as follows:—A is the socket for receiving the spigot end of the trunk, C the flange for fixing the valve plate over the body, B O are the beat valves, D the outlet or rising main, and G the air-chamber. Fig. 380 is a side elevation of a ram, having the rising main coming off the top of the air chamber; D is a door or plate for examining the interior parts of the ram.

Having described and explained the different rams and their action, I will proceed to show one or two fixed, and to describe the modes of fixing, &c. I may first mention that water rams, like all other engines, cannot do work of their own accord, but will be dependent upon some of the prime moving elements, let the power come from where it may. Therefore, the useful effect of this apparatus will be governed by a certain force, generated in this case by a running stream or head of water, and determinable by the well-known laws of mechanics. The simplicity of the operation of this machine has been the means of its ranking as one of the most beautiful philosophic instruments which has hitherto figured in the pages of any writer on natural philosophy and hydraulics; and its durability and simplicity render it one of the most important and valuable self-acting machines yet developed. This hydraulic machine is especially useful for forcing water where large quantities can be allowed to run to waste.

(*To be continued.*)

COMBINED WHEEL AND LEVER BACK CENTRE.

THIS combination has been invented to prevent the loss of time, expense, and trouble experienced by workmen in substituting a wheel centre for a lever centre, or the reverse, the necessity for which, in all classes of work, is daily, in some trades hourly, experienced. The result has been obtained without resorting to any complications of mechanism, and its great superiority over the old type is thus secured without additional cost. It involves no additional cost, though double the convenience of two centres: is equally effective either with lever or wheel; no time is wasted in substituting one form for the other, and it can be used as a self-acting gauge, insuring accuracy in work. Fig. 1 shows back centre in use with lever. . Fig. 2 shows back centre in use with wheel. To use the back centre with a wheel, place the loose pin A in the hole B, and throw the lever back out of the way. To use the back centre with lever, place the loose pin A in the hole C, thus securing the lever in place. Either change can be effected in two seconds. The sole patentees and manufacturers are Messrs. T. B. Barker and Co., of the Universal Gas Engine Works, Scholefield-street, Birmingham.

FIG. 1.

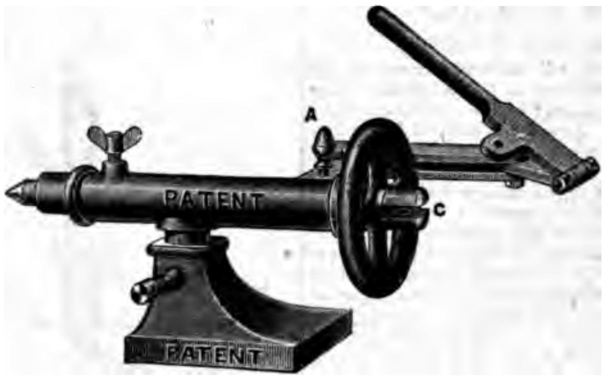

FIG. 2.

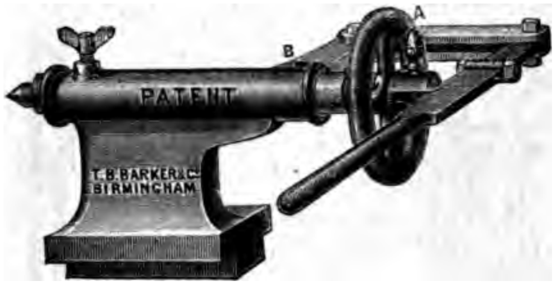

RAISING, LOWERING, AND SECURING SHIPS' BOATS.

A SIMPLE but apparently very efficient apparatus for lifting and securing ships' boats has been recently patented by Messrs Harland, Wolff, Wilson, and Pirrie, of Queen's Island, Ireland. The first two names will be recognised as those of the celebrated firm of shipbuilders, and we may take it that they are thoroughly satisfied as to the merits of the invention, the chief object of which is to enable the largest boats to be got outboard by a few hands instead of the large number now generally necessary. The improvements may be carried out by various arrangements of levers, wedges, cams and other mechanical appliances, but the patentees prefer the following arrangement shown in detail in Figs. 1, 2, and 3.

Below the bottom of the boat, when it is resting upon the chocks, are two shafts at a distance apart from one another, and at right angles to the keel. The shafts turn in brackets bolted to the dock or platform on which the boat is carried. Each axis has standing out from it two short arms A, carrying between them a roller B which comes just below the boat's keel, when the boat is in its place upon the chocks. The outer end of each axis has a socket standing out radially from it, into which a long bar can be inserted. When the boat is resting upon the chocks, the short lever arms are horizontal or nearly so. When the axis is turned by the bar, so as to cause the roller at the end of the short lever arms to lift the boat, a little more than a quarter turn is given to the axis, whereby the short lever arms are moved somewhat beyond a vertical position, as indicated by the dotted lines in Fig. 1 so that the weight of the boat has then no tendency to turn the levers back again in the opposite direction. The boat can in this way be lifted at each end, say about six inches, thus freeing the outside chock, which can then be tumbled over, and the slack of the falls taken in and secured, the levers are then partially reversed to free the boat's keel, and the boat swung out. The roller at one end has a flange D round its end furthest from the vessel's side: this enables the boat's keel to be readily placed upon the rollers when they are raised and ready to receive the boat when being swung into place. When the boat is being lowered, the jaws C on the two arms which carry the roller come one on either side of the keel. In this way the keel of the boat on being lowered on the rollers is readily caught, held laterally, and guided into the fixed blocks at each end by the jaws C, and then lowered into its place by the reverse action of the levers, while the weight

Fig. 1

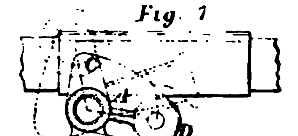

Fig. 2

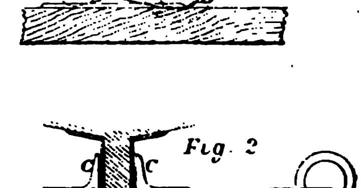

Fig. 3

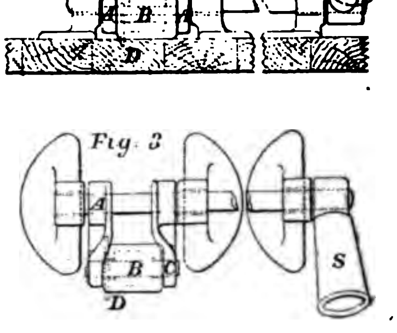


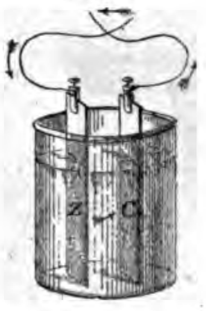
of the boat is borne by the rollers. The castings holding the rollers are constructed with a stop resting on the deck, and the centres arranged in such manner that when the bars or handles are pulled over to the full extent, they cannot be thrown back by a weight on the rollers.

THE DYNAMO: HOW MADE AND HOW USED.—III.*

By Selimo R. Bottone.

§ 4. THE student will do well to compare the effects produced on the galvanometer by the battery current, and by the current obtained from the magnet. Any single cell will do for this purpose; and in order to have an intelligent perception of what takes place, the student must bear in mind, that *in* the battery itself, the electricity (undulatory movement of the molecules) passes from the zinc to the negative plate (be it copper, silver, platinum, or graphite), while *outside* the battery, the electricity passes from this latter round through the wires, galvanometer, or other circuit open to its passage, back again to the zinc plate (See Fig. 4, where the direction of the undulation, or "current" is shown by the arrows; the plate marked Z being zinc, the one marked C being carbon, copper, or other conductor; W W being the wires forming the *poles* or *electrodes*). If the positive pole (the one from which the "current" is flowing: the wire attached to the C plate) of such a battery be connected to the galvanometer by means of the binding screw marked "over," the other pole being attached to the other binding screw, the north pole of the needle having previously been adjusted so as to lie between the two binding screws, it will be found that the N. pole of the needle will deflect to the *left* of the line of the coil; the operator being supposed to be standing at the binding-screw end of the galvanometer. Since the wire of our coil returns *below* the needle, it is evident that a positive current (an outflow of undulation) passing *over* the north pole of a horizontally suspended needle, or a negative current (an influx of undulation) passing *under* such a north pole, causes it to deflect to the *left*.

Fig. 4.



If we disconnect the battery, and reverse the connections, *id est*, join the negative pole (the wire coming from the zinc) to the binding screw marked "over," the other pole being connected to the other screw, the opposite effect results—viz., the north pole now deflects to the *right* of the coil. This will be understood by reference to Fig. 5, in which *a* represents the effect of the positive current flowing *from* the operator *over* the needle, the N. pole in both illustrations being nearest to him; in *b* the positive current is supposed to be flowing *from* the operator, *below* the needle, in either case returning to the battery the opposite way.

§ 5. This effect will enable us at once to recognise, by means of our galvanometer, the *direction* in which a current is travelling; for, on connecting the two terminals of any source of electricity to the binding screws of the galvanometer, whilst the N. pole is in a line with the coils, between the two binding screws, the operator facing the north pole of the needle, it is evident that if the N. pole of the needle is deflected to the *left*, the terminal attached to the binding screw marked "over" is *positive*; but that, if the N. pole deflects to the *right*, then the said terminal is *negative*. It must be borne in mind that by the term *positive* in this connection is meant the point *from* which electricity is flowing, negative being the point *towards* which it is flowing, or *at* which it enters.* This power of recognising the direction of a current will be found of great service to us in the construction of the dynamo.

§ 6. Returning now to our experiments with the magnet (see latter portion of § 3), and using in preference a straight soft iron rod, about 6in. in length, and ½in. in diameter, coiled with about 100ft. of No. 24 covered wire as our armature, and a good bar magnet to produce the electrical effects, we shall find, on coupling up the armature wires to the galvanometer, and approaching one end of the armature to or receding it from the N. pole of the magnet, that the electrical flow set up is always in one direction in approaching or making contact, and in the opposite direction on receding or breaking contact. Fig. 6 will make this clear. The arrow at *a* shows the direction of the current produced on approaching or making contact with the N. pole of a magnet; *b* illustrates the direction of current produced on receding from or breaking contact with the N. pole of a magnet. If now we reverse the experiment by presenting the S. pole of the magnet to the coiled armature, we shall find that the direction of flow is also reversed; that is to say, the *withdrawal* of a south pole produces the same effect as the *approach* of a north pole, and *vice versâ*, the *approach* of a south pole is equivalent in its effects to the *recession* of a north pole. It must be noted that the direction in which the wire is coiled round the soft iron rod (or armature), while it has no influence on the direction of the electrical current set up round the iron rod (which is always the *reverse* to the hands of a clock in the face *approaching* the north pole) determines the extremity of the said wire at which the current leaves or enters the coil. In the figure we have supposed the wire to be wound from *left* OVER towards *right*; had we wound our rod from *left* UNDER towards *right*, the opposite ends of the wire would have been respectively + and —. This must be borne in mind when we proceed to actual work.

Fig. 5.

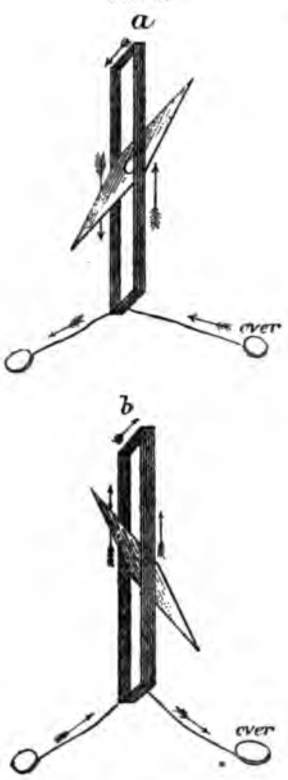


Fig. 6.

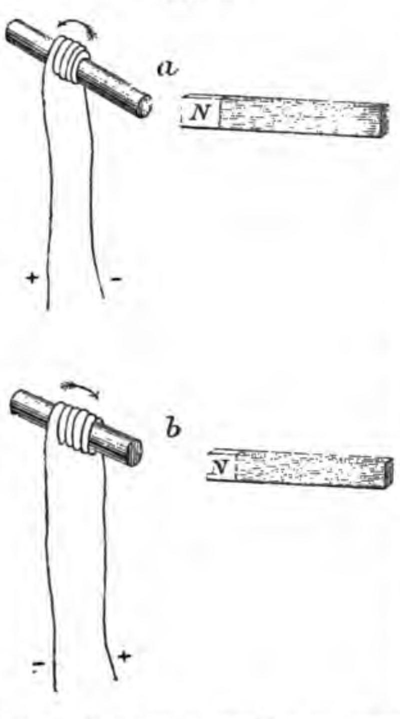

§ 7. *Currents can produce Magnetism.*—If we take the coiled soft-iron U, of which we made use § 3, and apply it to pieces of soft iron, nails, filings, &c., we shall find that it possesses little or no magnetic power of attraction; but if we couple the projecting ends of the coiled wires one to each terminal of a single-cell battery, we shall find that the U will become powerfully magnetic, retaining its magnetism as long as electricity flows around the coils, but losing nearly all the instant that the flow is caused to cease, either by breaking connection with the battery, or by any other interruption. The rapidity and completeness with which the iron loses its magnetism depends almost entirely on its *softness* and *purity*. Anything which tends to put a strain on the molecules of the iron, such as hammering, filing, twisting, sudden cooling, vibration, &c., render it liable to retain magnetism, or increase its *coercitive* force: whereas raising to a high temperature and very gradual cooling, which allows the molecules to range themselves with little or no strain, furnishes a soft iron, eminently incapable of retaining magnetism, or possessing little *coercitive* force.

PATTERN MAKING.—XIV.

(*Continued from page* 594, *Vol. XXXVII.*)

Flywheels and Strap Pulleys

ARE made by similar methods, and permit of very little variation in design. We may divide them into two classes simply—those with cast, and those with wrought iron arms. The former are the more rigid, the latter are the safer.

Taking flywheels first in order, we shall find that except in the case of standard wheels made for engines which are a speciality, and which, therefore, require a repetition of castings all exactly alike, very few flywheels are made from patterns: but are struck up. If, however, we had to make a pattern for one of these standard wheels, or even for a small engine of one or two horse-power or less, we should proceed as follows:—

Build up the rim in courses of segments, as in the case of a toothed wheel, p. 143, and lock the arms together, according to directions also previously given, p. 191. When the rim is built up to half its full thickness *plus* half the thickness of an arm, turn its inner portion to the correct diameter, and notch out recesses to receive the ends of the arms. Glue these in, and above them glue on the remaining courses of segments. Then complete the turning of the rim, and work the arms to shape. (Fig. 63.) If the wheel were large it would be more convenient to work the arms, before glueing them in place, leaving only the radii which merge into the rim to be finished in position. Suitable bosses will then be turned and screwed on the centre of the wheel, and the core print put on the centre of the one in the down side of the mould.

But suppose we have to make a large wheel, ranging anywhere between 3ft. and 12ft. in diameter. We should proceed in this way. W

* *All rights reserved.*

* We have no desire to enter into any theoretical matters in these papers; but comparing electricity to sound, we may say that in blowing a blast in a trumpet, the trumpet may be considered as *positive*, while the ear of the listener may be considered as being negative. The chief difference seems to be that electrical undulations seem to require a complete circuit wherein to display their effects, sound undulations being bound by no such conditions.

should make a board chamfered like a loam board, and, like it, fastened to a centre bar, to strike a ring of sand of the same diameter as the periphery of the wheel, the top edge of which ring would be struck off level by the board to form the joint for the top of the mould. The disc inclosed by this ring would be struck to a true plane of sand at a depth below the joint equal to the thickness of the wheel rim. During the process of striking, the sand forming the outside of the rim will break away and fall down to a certain extent. A sweeped piece, worked to the proper radius and depth, will therefore be necessary to mend this up smooth and sharp. (Fig. 64.) Further, if the flywheel be shallow, the striking board must be modified a little. From the inner diameter of the ring right away to the centre it must be cut deeper by 2in. or 3in., thus recessing the bed below the edge of the rim by that amount, Fig. 65. The object of this is to get sufficient depth of sand and grid room in the cores which are to form the arms. There should not be less than 1½in. or 2in. for sand, and 1in. for grid allowed over the thickest part of the arm.

Two cores, placed face to face, make up an arm. They are jointed in the circular plane of the wheel, and extend from the inner diameter of the rim to the central boss. If, then, our bed were level with the edge of the rim, our corebox would be just half the depth of the rim. If the corebed were sunk lower than that edge, the corebox would be thicker by that amount than half the depth of the rim.

To make it, it must be sufficiently wide to give 3in. or 4in. in breadth of sand for jointing where the cores abut against each other around the boss. There should also be enough sand to include the radii or hollows where the arms sweep into the rim. It will be framed together in the usual fashion of rectangular coreboxes, with two sides, Fig. 66, having their two ends kept in position by shallow grooves. The end, which represents the inner diameter of the wheel, will be hollowed to the same sweep as that diameter. At the opposite or boss end, two symmetrically-shaped joint blocks, *a a*, will be fitted, including between them an angle of 60°, that being the angle which the cores will occupy in relation to each other in the mould for a six-armed wheel. On one edge of the box so made, a bottom board will be dowelled.

We have now our box in outline, requiring the arm to complete it. As our cores are to be jointed in the centre, both top and bottom cores are evidently to be alike, and our arm will represent only a *half* section.

Get out three pieces of wood, representing respectively the straight portion of the arm, *b*—the sixth part of the boss including the hollow by which it sweeps into the straight arm, *c*, and the sweep curving into the rim *d*, each in half section. Dowel or screw these in the centre of the corebox on its bottom board. A sixth part also of the core print may be put on the boss segment, if the box be deep enough to allow of this, or the core may be centred in the mould after the cores are laid in place. Notches, *e e*, will be cut out on the top edges of the core box to take the grids, Fig. 67. A grid is a cast-iron frame of latticework, which the moulder uses for the same purpose as the bricks and plates in a loam mould—viz., to give rigidity to the core. Those portions of the grid which project beyond the core are in this case also used for the purpose of screwing the top and bottom cores together before casting.

The cores, when made, are dried, blacked, jointed, and laid in the mould, as indicated by the dotted lines in Fig. 68. There will then be open spaces *a* between each double core, which must be filled up to form that portion of the rim not already formed by the sweeped ends of the arm cores. These intervals may be filled up either by distinct cores, involving a box, or by a sweep against which the moulder will ram green sand, similar to the one used for mending up the outer sand, but cut in the opposite way—viz., hollow, and of the same radius as that of the inner part of the rim.

Then there remains the top of the mould. This is struck by a board, and in loam generally, sometimes, however, in green sand—viz., ordinary moulding sand. If in loam, it is struck on a circular cast-iron plate, roughened over as usual to hold the loam; if in green sand, a top part box will be used. If the cores are deeper than the rim, as in Fig. 68, the board will be shouldered as in the bottom; in fact, the same board will suffice for striking both the top and bottom. This completes the wheel as far as the pattern maker is concerned.

But in wheels running at high speeds people have learned to distrust cast iron, and though the massive rim is still retained, it is preferable to make the arms of wrought iron. In wheels made entirely of cast iron the disproportion between the heavy rim and the comparatively slight arms sets up initial strains within the casting, which become a perpetual source of insecurity. Hence reason and experience have decided against the use of such wheels for quick-running machinery, and in favour of those with wrought-iron arms. The strength of these also must bear a proper relation to the momentum of the wheel, else they will twist off close to the boss, as I have seen in more than one instance.

To make such a wheel, quite a different mode of procedure must be adopted to that just described. In the first place we shall make the rim in another way, though still without a complete pattern. We shall have no board, but a sweep of exactly the same section as the wheel rim, and a foot or two longer (according to the size of the wheel) than the sixth part of its circumference (Fig. 69.) Exactly one-sixth part of the inner circumference of the wheel (= its radius) will be marked on the inner edge of this sweep, and on the centres so marked prints and half bosses for the reception of the arms will be fastened.

Then the sweep with its bosses and prints is rammed up level with its top face, and drawn from the sand. It is then carried round exactly one-sixth of its circumference, and its right hand print and boss is dropped into the impression just made by its left-hand print and boss. There the sweep is again rammed up, to be again withdrawn and removed, until the ring, with its six bosses and six prints, is complete. The reason why prints are used is obvious on a moment's consideration. The wheel being moulded in segments renders it impossible to ram up a top part in place, as in the case of a pattern, and, as a consequence, the only possible way of making the top half of the boss is by a core.

The corebox will consist of a rectangular frame having one side sweeped to the inner curve of the rim, and a bottom board on which will be fastened the half boss and print. (Fig. 70, enlarged for distinctness.) These must be exactly in the centre of the box, and of exactly the same shape and size as those which are fastened on the rectangular print; otherwise there will be overlapping of joints in the casting. In fact we always joint the two halves and turn them together; then, taking them apart, use one for the corebox, the other for the pattern. The print in the boss is of the same diameter as the wrought-iron arms, and that part of the arm which enters the boss is jagged or notched in order that the cast iron may embrace it the more securely.

The mould for the rim having been completed, the arms are laid in the prints ready for their reception, the rectangular cores are laid over their ends (each in its print), and the entire ring is covered with a flat surface of loam or green sand. The rim is then cast and allowed to cool. When cool, but *not quite cold*, the boss will be cast on the other ends of the arms, which also will be notched to prevent possible loosening.

The reason why the boss is cast on after the ring has cooled, is that the contraction of the ring in cooling is so largely in excess of that of the boss, that the rigidity of the latter, by preventing the arms from coming inwards, would infallibly either bend the arms or fracture the rim. Hence the boss is always cast when the rim has nearly, but not quite, done contracting, there being, of course, a slight amount of shrinkage on the boss.

A complete pattern boss is wanted jointed in the centre of the arm bosses in a direction parallel with the plane of the wheel. The boss mould, also, is made in halves, and usually dried.

(*To be continued.*)

PROF. KLINKERFUES' IMPROVED HYGROMETER.

An improved construction of hygrometer has been recently patented in this country on behalf of Professor Klinkerfues, director of the Göttingen Observatory. The invention relates to hair hygrometers, and is also applicable to other instruments in which the hygroscopic qualities of the human hair are employed for indicating the relative moisture of the atmospheric air in combination with air pressure and temperature of air. As a hair or a hair-string, of quality and preparation as used for hygrometers or weather instruments generally, changes its length not in geometrical proportion to the changes of relative moisture of the air, and as [illegible]

FIG. 1.

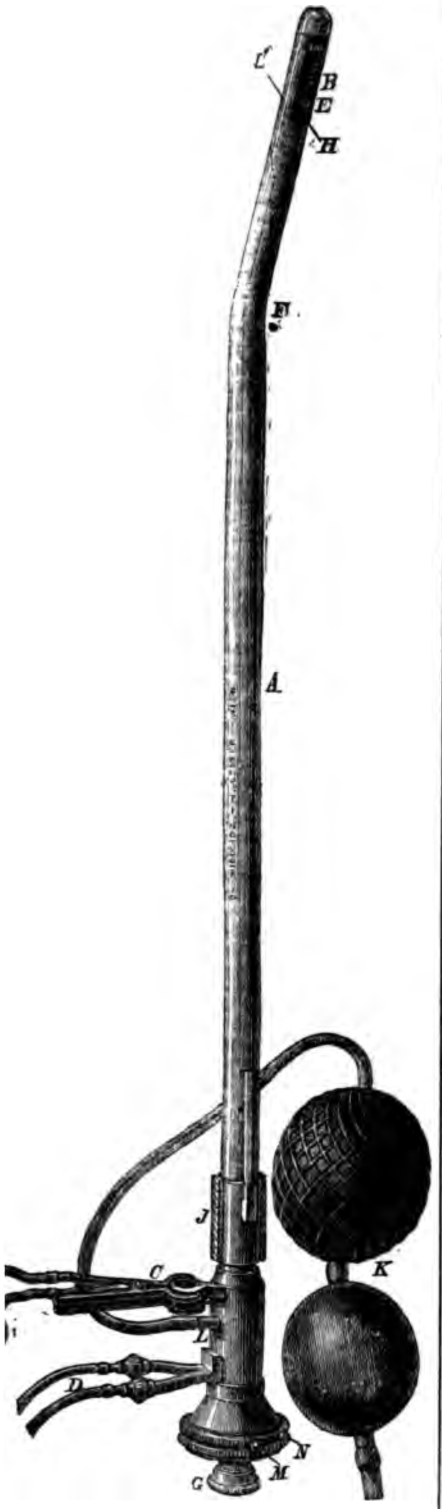

FIG. 2.

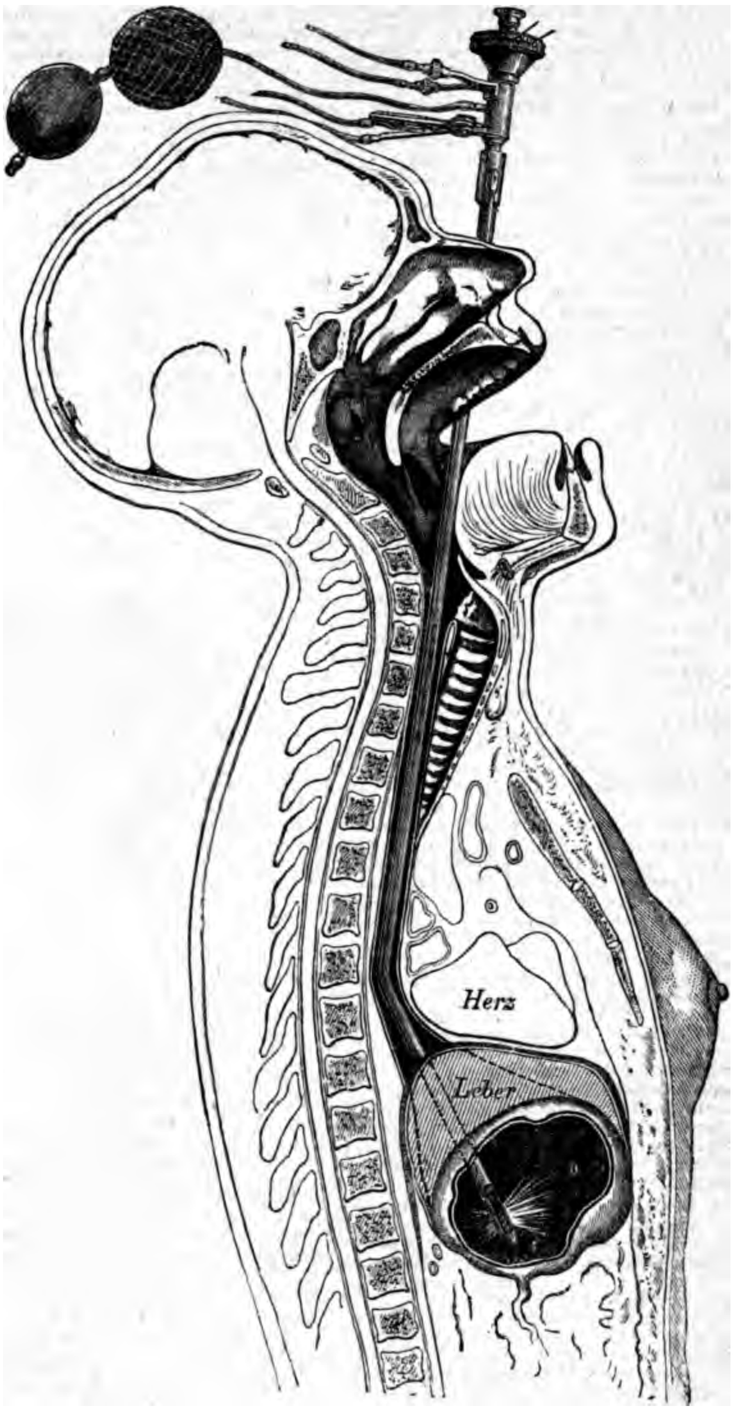

the part examined, the image being received by eyepiece either direct or, where necessary, er being diverted in the proper direction through sms.

.eiter's original gastroscope in particular was a rvel of ingenuity in the various arrangements allowing the walls of the stomach to be ıminated and examined by the aid of lenses, but apparently been found too complicated for .ctical use, and a simplified form is described by . J. Mikulicz (with a great elaboration of ail on all points), which has been devised by n in collaboration with Herr Leiter.

The tube A (Fig. 1) is 65 cm. long and 14mm. ck, and is bent at F at an angle of 150°. At B is platinum wire for the electric light covered with lass plate and connected, by wires running up tube, with the key C and a Bunsen battery. o water-tubes also run up the main tube, their ls being shown at D, a constant stream of water ng maintained during the observation so as to vent the lower end of the tube becoming heated. ere is an additional tube for pumping water into stomach, which commencing at the indiarubber ls K passes into the main tube at L and is conted-to L' where there is a small aperture.

The optical apparatus consists of a prism and an objective at E (the prism being right-angled and acting as a reflector to transmit the rays from the side of the instrument up the tube), a second prism at the bend at F, and an eyepiece at G. To prevent the glass plate at B from being smeared whilst the instrument is passed down the œsophagus a metal shutter H slides over it, and can be drawn back by moving the collar at J.

The fact is enforced in italics that the instrument can be introduced into the bottom of the stomach without difficulty, and Fig. 2 is given in illustration of the statement; another figure showing the advantage of the bent end in allowing different parts to be illuminated and observed by simply rotating the tube, the stomach being distended to facilitate the excursions of the tube. The authors' pamphlet contains not only a very full description of the instrument, but minute directions for its use.

Dr. T. Oliver describes a successful experiment of examining the interior of a patient's liver by one of the small Swan incandescent lamps described by Mr. Stearn. The apparatus used was an electroplated brass tube 9½in. by 11-16ths inch, closed at the lower end by glass, down which was inserted a narrow cylinder carrying a lamp and wires. Mr. J. B. Payne (a Fellow of the R. M. Society), who devised the arrangement, considers it to be much simpler than Leiter's platinum wire, as it gives a perfectly pure light and develops less heat. He says "a Swan's electric lamp is used—the filament of which is carbon, and rendered incandescent by means of battery power. It is hermetically sealed in a glass shade; and water, conveyed to and fro through very small brass tubes, is made to circulate round the lamp. The light from this lamp is perfectly pure, and exhibits the condition of things in their true and natural colour. For prolonged observation I should prefer to use either a Grove's or Bunsen's battery, but in the demonstration just referred to, four cells of a modified Leclanché battery were employed and answered admirably. It is advisable to have as great a pressure as possible for the water supply, so as to insure perfect circulation, and for this I suspended from a hook fixed near the ceiling of the room a tin can containing water, connecting it with the brass tubes by means of lengths of indiarubber tubing."

BERTHELOT ON EXPLOSIVES.—IV.

BETWEEN these two limits there is observed an entire series of intermediate stages of an unlimited number, as is shown by the different methods of burning of dynamite, and the influence of tamping which allows the transformation from burning into a real detonation, if the tamping is sufficiently resisting. Finally we may cite the inequality of the effects produced by the successive explosions of the charges of the same agent, which [illegible] by influence within limited distances beyond which the explosion will not propagate [illegible]. We [illegible] refer to chemical phenomena. That [illegible] decomposition prevails when the explosive substance contains sufficient oxygen to experience a complete combustion as occurs for nitro-glycerine and [illegible], besides it is necessary that this total combustion shall have actually taken place, which does not necessarily happen, especially [illegible] performed at a temperature as low as possible. But it often happens that the oxygen is insufficient, or that the first reaction gives rise to a wasteful expenditure of this oxygen as is the case when nitro-glycerine burns slowly, with the production of nitrous vapours and of fixed or gaseous substances incompletely burned. Under these circumstances the possible decompositions are numerous [illegible] their number depends on the temperature, on the pressure, and on the rapidity of the heating. We have already remarked upon this in the case of ammonium nitrate; it may be observed in general in organic substances, decomposed by heating.

Among these decompositions those which develop the most heat are those which produce the most violent explosive effects, other conditions being equal. This fact is evident when the volume of gas produced [illegible] remains in the same [illegible]. But it is also verified in [illegible] the decomposition giving rise always to a maximum of pressure, as I have shown elsewhere. In the other hand this fact does not obtain as a general thing in reactions which are produced at the lowest possible temperature. If then, the [illegible] produces in a given time a quantity of heat sufficient to carry the temperature up to [illegible] degree which corresponds to the most violent [illegible] decomposition capable of giving [illegible] heat, and [illegible] completely by this [illegible] these explosive effects [illegible]. The opposite will [illegible] tended to the [illegible] energetic [illegible].

Finally the multiplicity of the possible reactions [illegible] intermediate effects, and [illegible] according to the [illegible] by M. [illegible]

time, into the midst of the first layers of the explosive substance reached by the shock.

The phenomena which we have described have had reference to solid or liquid explosives, but the gaseous compounds and the detonating mixtures of gases give similar results, these throw a still greater light on the theory. In reality the chemical transformation of such a gaseous mixture may act with very different rapidities according to the mode of propagation of the decomposition or of the burning. Let us begin with a compressed gas formed with the absorption of heat according to its elements, such as hypochlorous acid ($Cl + O = ClO$ absorbs − 7·6), acetylene ($C_4 + H_2 = C_4H_2$ absorbs − 61·5) or cyanogen ($C_4 + N_2 = C_4N_2$ − 74·5). Such a gas is decomposed in inverse proportion to the liberation of heat. This, for instance, is what we obtained with the hypochlorous gas, heated below 100°C or traversed by an electric spark, or placed in contact with a body in ignition; the gas detonates at once, reproducing chlorine and oxygen. But it is not the same with acetyline nor with cyanogen. These gases neither detonate by the influence of heating nor by the influence of the electric spark, although they are decomposed by them, little by little, and without exploding. On the other hand, I have found that a quick shock of mercury fulminate will cause them to detonate rapidly with considerable flame, separation of their elements, carbon and hydrogen in the case of acetylene, and carbon and nitrogen in the case of cyanogen. The experiments have recently been described in the present work.

The explosive mixtures formed by the union of oxygen with a combustible gas may also burn with extremely varying rapidities, according to the method of the propagation of the chemical reaction. We have cited the experiments of M. Bunsen, who thought it possible to fix the rapidities of combustion of a mixture of hydrogen and oxygen gas, in equivalent proportions, at 34 metres per second, and that of a mixture of carbon monoxide and oxygen at only a metre. These are experiments based on the retrogradation of the flame back into the mixture, while flowing out into the atmosphere through a narrow opening. Having recently undertaken these experiments with M. Violle under different conditions, we have observed rapidities incomparably greater. Our method of operation was as follows: On each occasion we filled under atmospheric pressure with an explosive mixture, an iron tube 5 metres long, having an internal diameter equal to 5mm., capable of being sometimes kept open and sometimes closed at its extremities, or else a lead tube 40 metres in length, or sometimes a thick indiarubber tube 40 metres long. By means of a special arrangement we are able to register the passage of the explosive wave, first at the beginning of the tube, then further on, and finally at the end of the tube, and also we were able to measure the time elapsing between these different passages. These experiments were made with the tubes which were sometimes opened at one extremity and sometimes closed; on some occasions they were placed horizontally, and on others they were arranged vertically, and under different pressures. They had proved to us that the detonation is propagated with a rapidity equal to thousands of metres per second, as well for the mixture of hydrogen and oxygen as for the mixture of carbon monoxide and oxygen.

The difference between these results and those which were obtained by M. Bunsen may be explained by the variance in conditions. The gases burned in the earlier experiments were cooled by contact with the air, and the explosive wave not produced. The difference between the two kinds of combustion appeared analogous to that which exists between the simple burning of explosive substances—an operation in which the movement of the different particles takes place confusedly and in an independent manner, and their sudden detonation, provoked by a fulminating cap, an operation in which the movements become co-ordinated. Hence the effects of temperature and of pressure attain their maximum, and are propagated with an incomparably greater rapidity. Some of these experiments made with the fire-damp of mines [illegible] an analogous interpretation.

So far we have regarded the development of the explosive reactions either from the point of [illegible] in a homogeneous system [illegible] parts are maintained at the same [illegible] from the standpoint of their propagation in a system equally homogeneous, to [illegible] directly by means of a body in [illegible] a violent shock. In these last [illegible] the study of explosive substances [illegible] the existence of another method of [illegible] the reactions in an explosive centre, propagating the reactions taking place at a distance and by the propagation [illegible] of the air or certain solid bodies [illegible] participate in the chemical [illegible]. We now wish to speak of what are called [illegible], whose existence was [illegible] by [illegible] from certain known facts relative [illegible] explosion of several buildings [illegible] considerable space from each other, as in catastrophes occurring in powder mills. Attention has been specially directed to this class of phenomena by the study of nitro-glycerine and gun-cotton.

We will begin by giving the most important characteristic facts. A dynamite cartridge made to detonate by means of a fulminate cap causes the adjoining cartridges to detonate, not only by contact and by direct shock, but even from a distance. In this way an indefinite number of cartridges, arranged in a regular course, may be made to detonate. The distances to which the explosion may be propagated are relatively great. Thus, for instance, cartridges being contained in rigid metallic envelopes and placed on a resisting soil, the detonation produced by 100 grains of Vonges' dynamite (75 per cent. nitro-glycerine, 25 per cent. randanite, that is to say, very finely divided silica) communicates itself 0·3 metres of distance, according to the experiments of Captain Coville. D being equal to the distance in metres, and C the weight of the charge in kilograms, the experiments of this officer show that D = 3·0 C. When the caps were laid on a rail, D was found to be equal to 7·0 C. On soft or ploughed up earth the distances, on the contrary, are less. When a cartridge is suspended in air there is no detonation by influence, perhaps because the cartridge not being fixed can recoil freely, which diminishes the violence of the shock. Nevertheless, there are experiments which show that the air suffices for the transmission of the detonation by influence, although with greater difficulty and requiring a greater mass of the explosive. With a dynamite less powerful in nitro-glycerine (55 per cent. of nitro-glycerine and 45 per cent. of the argillaceous ashes of boghead coal), contained in similar cartridges, and placed along the ground, the experiments of Captain Pamard have given the smallest distances: D = 0·90c. If metallic envelopes having less resistance are used, the distance at which the explosion is propagated is likewise diminished. Dynamite simply spread along the ground ceases to propagate the explosion. The experiments performed in Austria have given similar results. They have shown that the explosion is communicated either in the free air with intervals of 4cm., or else through pine boards 18mm. thick. In a lead tube with a diameter = 0·15 metres and a metre in length, a cartridge that is placed at one extremity has caused the detonation of a cartridge at the other end. The explosion is still better transmitted through tubes made with wrought iron. Couplings of the tube diminish their aptitude for transmission. An explosion which is propagated in this matter will go on weakening itself from cartridge to cartridge, and even change its character. Thus, according to the experiments made by Captain Müntz at Versailles, in 1872, a first charge of dynamite, exploded directly, excavated a funnel-shaped hole in the ground with a radius of 0·30 metres: the second charge, detonated by influence, produced an opening of only 0·22 metres: the effect of the detonation was then reduced. This reduction should manifest itself towards the limit of the distance at which the influence ceases. In the same way four tin sieves were taken and located at 40mm. apart, and against each of them a small cylinder of gun-cotton was placed and the entire affair arranged on a board; 15mm. in front of the first sieve a similar cylinder was detonated. All of the cylinders detonated, but a progressive diminution was observed in the excavations produced in the board below each cylinder. According to these facts, the propagation by influence depends at the same time on the pressure acquired by the gas, and on the nature of the support. It is not even necessary that it should be rigid.

Finally, in operating under water at a depth of 1·30 metre, a charge of 5 kilograms of dynamite brought on an explosion of a charge of 4 kilograms, situated at a distance of 3 metres. The water then transmits the explosive shock, at least to a certain distance, as does a solid body. This transmission is so violent that the fish are killed in ponds without the sphere of a certain radius by the explosion of a dynamite cartridge.

(*To be continued.*)

MOUNTING PRINTS.

UNTIL improvements in photo-mechanical printing methods enable us to economically and conveniently impress the photographic image directly upon cardboard, the work of mounting prints will form a considerable item in the labour account of the photographer; as the public look with but little favour upon an unmounted picture, the number sold is comparatively small. A mounted photograph is seldom so flat and even as the original card, because the albumenised paper, expanded by the moisture of the adhesive material used, contracts in drying, and distorts the card mount; this distortion being generally so considerable, that in the case of a print mounted upon a large card, a decided concavity of the picture results, while a small card nearly covered by the photograph is generally drawn either into a gutter or a

. These disadvantages can be readily over- by adopting the simple and easy expedient of ning the prints, allowing them to dry, and causing them to adhere to slightly damped its by the application of considerable pressure. work of gumming the back of the photographs e very quickly performed if a broad brush is , but as the gumming of paper is now a distinct in London, it is more advantageous to send to be gummed, more especially when the s are printed upon whole. A ream of paper, same size as the ordinary sheets used for graphic purposes (17½ by 21½), can be gummed ndon for about 10s., this sum including the

The gummed pictures are next trimmed in sual way, when all is ready for the work of ting.

card is very lightly damped on the face with a ge, the gummed photograph is placed in ion, and the whole is quickly run through a graphic or a roller-press. Far less moisture is red than might be supposed, as the pressure s to the surface that water which has soaked the card, and the mounted photograph, when from the press, is, to all appearance, as dry it had not been damped at all; and, what is important, it has no tendency to curl. A th lithographic stone forms the best basis upon h to lay the print when the pressure is applied, sheet of smooth card or glaze board should be ver the picture before the leather tympan is d down upon it. Assuming the pictures to be dy gummed, about four hundred per hour can nounted by this method, and it must be mbered that the effect of the pressure is almost valent to rolling. The method to which we refer has long been in use by collotype printers, is country and abroad, for mounting their res, and we know of several instances in which been introduced with advantage in portrait os. A small lithographic or autographic press, ble for work up to about 12 by 10, can be ned for a very moderate sum.—*Photographic*

.

ANIMAL INTELLIGENCE.

OPTING the terse language of Shylock, we may ask, Hath a dog reason? And, falling a more lengthy style, we may inquire, Is its ning at all comparable to that of the human ? We think both these questions must be ered in the affirmative. Those who differ us will certainly admit that the possession by of a language of symbols must have an nous influence in increasing the power of his lectual faculties. So much, indeed, must this e case, that what is really only a difference of e is yet so stupendous that an intellect, the uct of the employment for ages of word signs, t be thought to be an altogether new and nal faculty, We are inclined to assert, how- that almost the sole essential difference een the intellect of the dog and that of the man be traced to the above cause. A dog can n, but not by using symbols. It employs the al picture of an object, the olfactory percep- of an agent, the auditory impression of a ding body for the terms of its premises. But sy as these may seem, yet the mind of the al successfully grapples with them. The dog es from the ideas of concrete things, although pable of abstraction and of the formation of a eption. Devoid of generalisations, it deals with culars; but it does reason; it substitutes one for another; it weighs and estimates at their value the successive mental images which nt themselves to itself. Everyone knows the ious memory of the dog, not only for what it een, but for what it has smelt and heard. The tory sense in many species is truly marvellous, its mental grasp or memory of the same is re- able in an equal degree. No division can tifically be drawn between the memory of a scape by a dog and the recollections of a n by a man. Moreover, the dog is not simply chanism, the result of hereditary action. The idual can learn new things—nay, even execute lex mental feats, for itself. The following nce, which forcibly illustrates the power of the ning of the dog, came under our personal notice. ntleman last season bought a middle-aged blue ter, which with his good qualities as a "wide- er" and "staunch pointer" combined the ty of retrieving partridges. When the snipe n commenced in October, the dog took no e whatever of the "longbills," but looked them as vermin and drove them away. After out about six times snipe-shooting, finding his master shot these birds, the dog stood at snipe, and, when killed, dropped it at the sman's feet. The instance is certainly re- able. Such a faculty of ready apprehension reditable performance of a difficult mental (for it must be remembered that he had his litary influences to overcome) would have been d with delight had it been manifested by a who had not the knowledge of spoken language. *neet.*

SCIENTIFIC NEWS.

THE death is announced of Dr. Henry John Hayles Bond, formerly Regius Professor of Physic in Cambridge University. The deceased gentleman was born in 1801, and in 1851 was inducted to the chair of Physic, which he held for 21 years. It was mainly owing to his advocacy that the Natural Sciences Tripos was established, and the study of medicine received rewards and encouragement from the University which it had previously unknown.

Mr. Cromwell Fleetwood Varley, F.R.S., M.I.C.E., &c., the eminent electrician, died at his residence, Cromwell House, Bexley-heath, on Sunday last. Mr. Varley will be remembered as the electrician of the Electric and International Telegraph Company, who were the first to successfully lay a cable across the Atlantic. He also patented many useful inventions, one of these being a musical telephone, which he produced in 1870, and which was played on at the Queen's Theatre, Long Acre, in February, 1877.

Mr. Thomas L. Plant, the well-known meteorologist of King's Heath, Birmingham, died suddenly last week in a carriage on the Midland Railway. Mr. Plant had kept a weather diary for over 40 years, and frequently contributed notes on meteorology to the newspapers and the proceedings of scientific societies. The deceased was in his 64th year.

Tempel's second periodical comet will probably be visible again soon. It was discovered on July 3, 1873, and on its return passed perihelion on August 27, 1878. The period is about twelve months shorter than that of Tempel's first periodical comet, which, discovered on April 3, 1869, returned to perihelion on May 9, 1873, and May 7, 1879.

According to Encke, the period of the comet of 1812 is about 70½ years, and on the 15th inst. it will be seventy-one years since it was in perihelion. There are reasons for believing that its period is somewhat longer than Encke calculated, so that another appearance may be expected at any time within the next few months.

The Saturday evening lecture, during the meeting of the British Association, will be delivered by Sir F. Bramwell, who will discourse on "Talking by Electricity" to the "operative classes," who are popularly supposed to form the audience at the Saturday evening lecture. In large towns such as Glasgow, Birmingham, and Liverpool, a considerable portion of the audience may no doubt be described as of the operative class, but at Southport there are not many of the sort of working men who go to scientific lectures. There is, however, during the fine weather, a regular influx of visitors to Southport on the Saturday, and the authorities are wisely taking measures to provide an "overflow" lecture should it be necessary.

The fate of the Dutch Polar Expedition was known soon after the reward was offered; but no one earned the money, for the news was brought by the *Nordenskjold*, which towed the *Louise* into harbour, and brought the members of the expedition and the crew of the *Varna*, and a despatch from Lieut. Hovgaard of the *Dijmphna*, which was in the Kara Sea, all well. It appears that the *Varna* was severely crushed by ice, and ultimately sank on July 24. The *Louise*, which left Bremen on the 27th of June, on a trading voyage to the Yenisei, lost her propeller.

Mr. Major has informed the Geographical Society that the ancient chart which was discovered in Iceland by Baron Nordenskjold, has arrived at Stockholm. Mr. Major states that in his opinion the relic is not a copy, as supposed, of Zeno's chart of 1558, but is of a later date.

The Brighton electric railway is so far successful that it is proposed to extend it for two miles along the whole front of the Esplanade wall. The car carries twelve persons, but on occasions sixteen, and runs at a mean speed of seven miles an hour, the gradient being 1 in 100. The average daily journey is 25 to 30 miles, and the average number of passengers daily, 350; but on last Bank Holiday the car ran for eleven hours without intermission, except to discharge and take a fresh load of passengers. The motor has a pulley of 5in., and runs at the rate of 700 revolutions per minute. This pulley, by means of a belt, drives a 10in. pulley on a countershaft, and that again drives a 12in. pulley on the axle. The track is about a quarter of a mile long, and in one direction the car runs at the rate of five miles, but returns at the rate of ten miles an hour. Ordinary flange rails with longitudinal sleepers laid on the shingle form the "line," and the rails alone are used as conductors, the loss of current being only 5 per cent. in dry, and 10 per cent. in wet weather. The cost is said to be only a little over one halfpenny per mile per passenger, i.e. the cost of carrying 12 passengers 60 journeys of half a mile is 15s. 8d., which includes 15 per cent. depreciation on £500; but the railway is capable of doubling its traffic without increasing its expenditure, except for gas.

A cabman in Vienna is said to use electric lamps on his cab, and in one announcement we saw it stated that he obtains the current from a dynamo mounted on or driven by the axle!

In fourteen days five accidents with hydraulic lifts are stated to have occurred in the City of London, four of them fatal. Some of these accidents are due to falls down the shaft through unguarded doors.

Some evidence tending to disprove the theory of the prophylactic action of copper has been submitted to the Académie de Médecine by M. Bailly, of Chambly, in the department of Oise. An experience of sixteen years' duration in connection with a factory, where workmen are largely employed in copper, has shown that the employés are not in any degree exempt from typhoid fever, choleraic diarrhœa, and other infectious diseases. M. Bailly's paper has been referred for criticism to the same commission which is already engaged in reporting on M. Burq's hypothesis.

Messrs. J. A. Allen, Elliot Coues, and W. Brewster have called a meeting, to be held in New York on Sept. 26, for the purpose of founding an American Ornithologists' Union.

Mr. Linfield, of Margate, who exhibited his flying machine at the Engineering exhibition last July, has tried it on the West Drayton Railway. The machine was placed on a truck, and drawn at a speed of thirty miles an hour, when, as the news "par." has it, "the machine rose in the air, but the inventor did not ascend with it." We believe he was quite satisfied with the performance.

A meeting of science and art teachers was held in Newcastle-on-Tyne on Monday, 27th August, 1883, and it was decided to form a branch of the Association of Science and Art Teachers. Dr. H. Evers was elected president, and Mr. William John Grey secretary. It is intended to hold a general meeting at Christmas at the Elswick Institute.

USEFUL AND SCIENTIFIC NOTES.

Gilchrist Scholarships.—The Gilchrist Engineering Entrance Scholarship at University College, London, will be open to competition at the end of September. The conditions of examination are this year somewhat altered, in a direction which places the scholarship better within the reach of those for whose benefit it was founded. The detailed regulations can be obtained on application to the secretary of University College. The following is a summary of them:—Candidates must be under nineteen years of age, and must send in notice to compete by the 23rd of September. The subjects of examination are—(1) Elementary mathematics, and (2) any two or more of the following five subjects:—Mechanics, mechanical drawing, essay on one of three given subjects in connection with mechanics or engineering, French or German, the use of tools, either carpenters' tools, or the lathe—wood or metal—or the file. The scholarship is of the value of £35 per annum, and is tenable for two years. There is also at University College a Senior Engineering Scholarship, awarded at the close of the session, of £80 value.

Punching Boiler Plates.—A most effective special tool in the Baldwin Locomotive Works is that for punching the rivet holes in tank sheets. The long sheet is fastened on a travelling trolley, which is moved under the punch by gearing. At each stroke of the punch the sheet moves the proper distance for the next hole, and it goes along automatically till every hole in the row is punched. The sheet is then moved so that another row comes in line with the punch, and the work proceeds of its own accord. As the distance between the holes is regulated by an unvarying train of wheel-teeth, each sheet is an exact counterpart of the other, and the holes come together with exactness ready for riveting.—*American Machinist.*

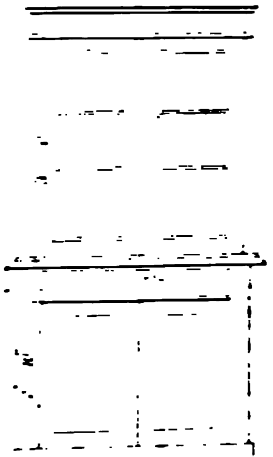

Fig. 2.

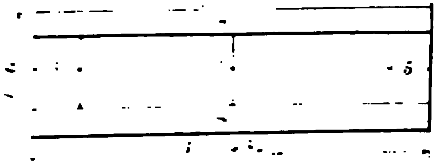

[illegible] ends and look for the best sides to turn outwards, then face them over and shoot the front edge straight and square, but be sure and make a pair of them. Now sharpen and set your trying plane fine, and then square the end meant for the top, shooting it with your trying plane, but always apply your square off the front edge and the outside, then breadth them to 1ft. 6in. They are now ready for setting off. To do this, place them in the screw of your bench with the front edge upwards and the insides together, then measure ¾in. from the top end, and with your marking awl draw a line across both edges; then measure 4in. from the first mark and draw another line; then measure ⅞in. and draw another line; then measure 2ft from the the third and draw another; then ⅞in from the last line and draw another line; then take your chisel and transfer the lines to the inside faces, cutting them in as deep as you can. The two lines nearest the top are meant for a frame to carry drawers, and those at the bottom are for the bottom of the cabinet. After you have transferred the lines to the insides, cut a groove between them right across front to back, and about ¼in. deep, then check them ½in. each way along back inside edge to receive the back, and place them on one side. Now take your board of ⅞in. and cut 2 pieces 3ft. 6in. long by 4in. wide, and 2 pieces 3ft. 6in. long by 3in., cut 2 pieces 1ft. 3in. by 5in., and another piece 1ft. 3in. by 3in.: now proceed to make a frame to carry drawer from the pieces like Fig. 2, mortising and tenoning it together. Then cut your bottom 2ft. 4⅞in. long by 1ft. 5⅛in., then cut another piece 2ft. 2in. by 1ft. 6⅛in., [illegible] 2ft. between, leaving 1in. at each end. Take your saw and run a sawcut ⅜in. from the front, then another 1ft. from the first, then another 1in. from the second, then 2in., and another 1ft. and another, and so on across ends, and the same at top and bottom, only leave 1⅛in. at the front. Then take your chisel and cut out all the 1ft. pieces and the first 1in. piece, leaving the 2in. piece in at the front: now take the frame you have made and the bottom, place them in the screw of your bench, front edge upwards; find the centre, measure ⅜in. on each side of centre, mark and draw lines across both edges, transfer the lines to both sides of the bottom and frame, place them flat on the bench, lay division on top with the ⅜in. piece projecting over the front of frame and the pins over the lines you have drawn on the frame and bottom; then with your marking awl draw lines along each side of the pins; then cut holes so that the pins will just fit into the frame and bottom; now dress and square up your other two 3ft. 6in. lengths to 3ft. 5⅛in., and dovetail them into the top of your ends, keeping the 4in. one to the front and allowing it to project ⅜in. over the front. Those that do not know how to dovetail had better get two cuttings, and work away until they learn, as no amount of writing will teach them. Next sharpen your smoothing plane, clean and sandpaper all the insides, and you are ready to put your cabinet together. First take your bottom, glue the pins of the division, place them in the holes made for them, turn upside down, and wedge up firm. Serve the frame in the same way, then turn it on one end, nail on the end along the bottom, serve the other end the same, turn it on its bottom, glue and drive the top rails, then it will have the appearance of Fig. 3; but be sure that it is square and fair, and we will finish it in our next. I forgot to say that the frame would project ⅜in. over the front of the ends.

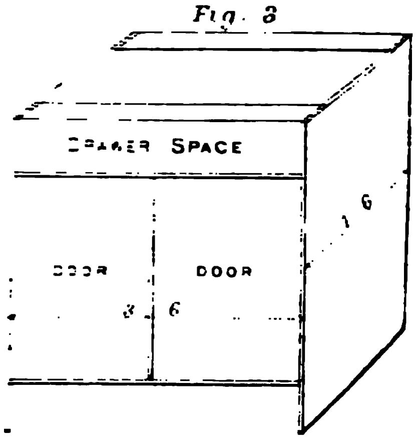
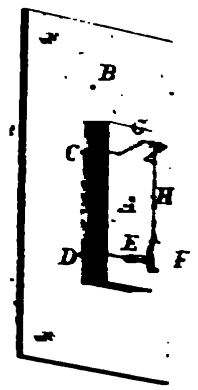
Fig. 3



A SIMPLE TELEPHONE TRANSMITTER.

[21770.]—I VENTURE to send a sketch and description of a microphone which I have found to



act successfully as a speech transmitter. It is the outcome of some telephonic experiments I have been making, and I do not recollect having seen one of this description in the "E.M." or elsewhere.

It consists of a matchbox (A), which is fastened on the board B (the copper wires, C D, conveying the electric current will hold it on the board). This acts as a sounding board. Resting on the box, and firmly held there by the wire D, is a small pointed piece of hard compressed carbon (E), such as is used in electric lighting, about ¾in. long and ⅛in. thick. Resting lightly on this is another piece of hard carbon (F) which is round, but having smooth flat sides, about ¾in. in diameter, and ¼in. thick, and is suspended from the loop G by the wire H. The whole may be covered in some way to protect it from the action of the breath, say, by a paper cover.

The finer the point of E, and the lighter F touches it, the more delicate is the microphone.

The battery and receiver are, of course, connected to it in the usual way.

Should any of "ours" feel inclined to try this transmitter, I should be pleased to hear the result of their experiments. **W. R. Hart.**

NOTES ON MAGNETISM.—I.

[21771.]—It is the object of the following notes to give a brief but clear exposition of the leading principles of magnetism considered theoretically. They will be found to embrace as much of the theory as is required for any examination of an elementary nature on the subject. They will also be found serviceable to the general student who wishes to obtain more exact ideas on the nature of magnetism than can be got from the generality of elementary textbooks on this subject.

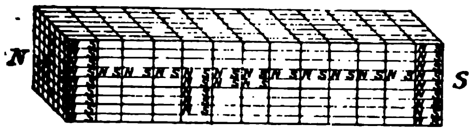


Fig 1

A Simple Magnet.—A simple magnet consists in theory of two points called the *poles*, joined by a straight line of fixed length called the *axis*. The force of magnetism resides exclusively in the poles. The axis is simply a line, having no magnetic properties, which holds the poles at a fixed distance apart. No magnet actually fulfils these conditions exactly. It is a theoretical conception used to simplify the mathematical treatment of the subject. A very long, thin, uniform bar of hard steel (such as a knitting needle), uniformly magnetised is the nearest approach we have to a simple magnet, the poles being situated at the ends of the bar.

Magnetic Polarity.—If A B are the poles of one simple magnet, and *a b* the poles of any other magnet, then it is found by experiment that one of the poles A repels *a* and attracts *b*, while the other pole B repels *b* and attracts *a*. The poles A *a* and B *b* are called *similar* poles, while A *b* and B *a* are called *dissimilar* poles. Whence we have the rule that similar poles repel, and dissimilar poles attract.

North and South Poles.—When a magnet is freely suspended, it is found that it always turns so as to make a certain angle with the meridian of the place. This position is the same for all magnets at the same place and time; but varies for different places and for different times. In England one pole always turns to within 30° of due north. This pole is accordingly called the North pole, the other pole being the South pole.

Law of Attraction and Repulsion.—It is found by experiment that the force with which the pole of one magnet attracts or repels the pole of another magnet, is different in different pairs of magnets. The force with which the pole A attracts or repels the pole *a* of a standard magnet at a given distance is called the strength of the pole A. It is found that the force with which two dissimilar poles attract, or similar poles repel each other, is directly proportional to the product of their strengths, and inversely proportional to the square of the distance between the poles. The magnets are here supposed to be sufficiently long to put the other pole of each out of the action of the poles experimented on. It is also found by experiment that the force of attraction or repulsion between two poles is influenced by no other circumstance. We may thus conceive the force of magnetism to be radiating uniformly in all directions from a magnetic pole.

Poles inseparable.—The poles of the same magnet are equal in strength. They are also *inseparable*, i.e., it is impossible to obtain a north pole, without, at the same time, a south pole of equal strength.

Magnetic moment.—The product of the strength of either pole of a magnet, and the length of the axis (or distance between the poles) is called the magnetic moment of the magnet.

Constitution of a Magnet.—Suppose a number of precisely similar and equal simple magnets to be joined together in a straight line, so that the north pole of any one coincides with the south of the next, thus:

N——SN——SN——SN——S

Then all the intermediate poles neutralise each other; only the end poles being effective. This combination is equivalent to a simple magnet, in length equal to the united length of the component magnets.

Suppose a number of simple magnets to be placed side by side with all the north ends pointing one way, thus:

N——————S
N——————S
N——————S
N——————S

Such a combination is not reducible to a simple magnet with only two poles. We have a number of north poles in a straight line, and a number of south poles in a straight line. If there are an indefinitely large number of precisely equal and similar simple magnets arranged in this manner, we get a line of north magnetism and a parallel line of south magnetism at a certain distance from each other, and these lines of magnetism take the place of the pole of a simple magnet.

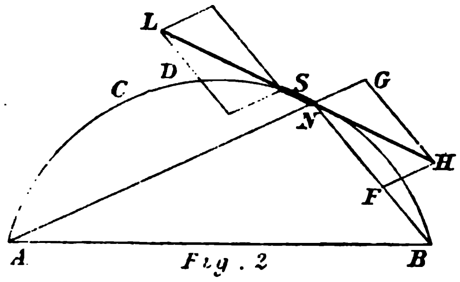

Fig. 2

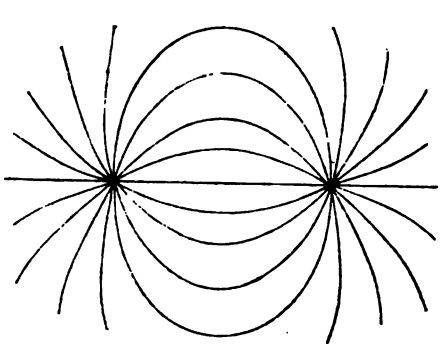

Fig. 3

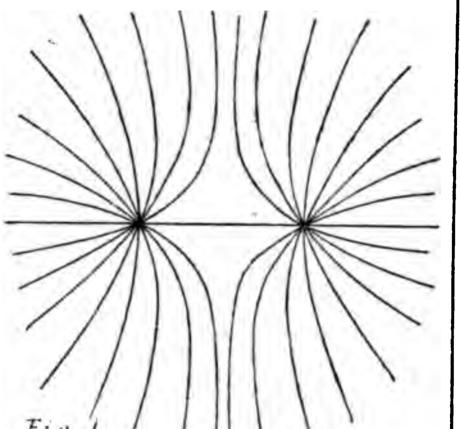

Fig 4

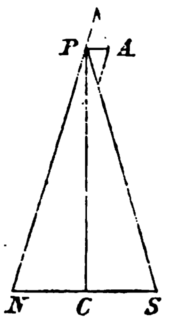

Fig. 5

Suppose now an indefinitely large number of precisely equal and similar simple magnets to be placed side by side so as to form a parallelopiped. We have now at one end a north magnetic surface, and at the other a south magnetic surface, and these surfaces take the place of the poles of the simple magnet.

We can now investigate the constitution of an ordinary bar magnet. Imagine an indefinitely large number of small simple magnets packed together so as to form a parallelopiped in the manner shown in Fig. 1. If all the component simple magnets are equal and of equal strength, all the poles in the body of the magnet destroy each other's action. There only remains the free magnetism of the north and south ends. Such is the constitution of a *uniformly magnetised* bar—i.e., one which may be regarded as composed of equal simple magnets of equal strength throughout. But if the component simple magnets are not of equal strength, then the bar is not uniformly magnetised. In this case the adjacent poles are not exactly neutralised, and we have north magnetism irregularly distributed over one half of the bar, and south magnetism over the other half of the bar. In all these cases there is no single magnetic pole; but, as will be shown hereafter, such a magnet has a definite magnetic moment. It is obvious that if a bar be very long in proportion to its thickness, and uniformly magnetised, it may be regarded as a simple magnet with the poles at the ends.

Any bar magnet may, by actual division, be broken up into elementary magnets in the above manner. It is seldom, however, that a magnet in practice is uniformly magnetised, the magnetism of the elements becoming stronger towards the middle. Such a magnet, as above explained, instead of having a single pair of poles, has an infinite number of north poles along one half of its length, and an infinite number of south poles along the other half of its length. It is, however, approximately equivalent to a simple magnet having its poles slightly within the ends of the bar.

Intensity of Magnetisation.—We have seen that any given magnet has a definite magnetic moment. The magnetic moment is proportional to the bulk of the magnet if the magnetisation is uniform. The magnetic moment of the unit of bulk is termed the *intensity of magnetisation*. Hence the intensity of magnetisation of any magnet is found by dividing its magnetic moment by its bulk.

Lines of Magnetic Force.—Let A B be the poles of a magnet (Fig. 2), and C a small magnetic needle. Then, if C is moved from A to B, along a line such that the motion of the needle is always in the direction of its own length, the path which it pursues is called a *line of magnetic force*.

The position which the small needle will assume at any point may be found in the following manner:—Let A and B be the north and south poles of the magnet, and N and S those of the magnetic needle. Then A repels N in the direction A N, and B attracts N in the direction N B. The magnitudes of these two faces are inversely as the squares of A N and N B. Consequently, if we take N G in A N produced, and N F in N B. such that

$$NG : NF : : NB^2 : NA^2,$$

and complete the parallelogram G N F H, the diagonal N H will represent the direction of the resultant force acting on N.

In the same manner, A attracts and B repels S, and the resultant force, S L, may be found in precisely the same manner. If N S be very short compared with A B, L S and N H are parallel, and N S will take up such a position that L S, S N, and N H may be in the same straight line.

If now we draw a curve, A D B, such that at any point in it the position of N S, found as above, is a tangent thereto, the curve A D B is a line of magnetic force. Some of these lines are drawn in Fig. 3. It must be observed that every line proceeding from one pole ultimately comes round to the other pole.

If two long magnets, A B and C D, are placed parallel to each other, so that similar poles, A and C, are opposite each other, while the poles B and D are far enough off not to exert any perceptible force on a small needle placed near B and C, a series of lines of magnetic force are produced of a different kind. The position of the magnetic needle at any given point may be found as before, Fig. 4 represents the lines of magnetic force in this case. They are all of infinite length, receding continually from each pole.

Magnetic Field.—Any portion of space traversed by lines of magnetic force is called a *magnetic field*. If the same lines of magnetic force traverse two portions of space A and B, then the strength of the magnetic field at A is to the strength at B as the number of lines of magnetic force that pass through a small area perpendicular to their direction at A, is to the number of lines that pass through the same area at B. Hence the magnetic force increases as the lines of magnetic force get closer together. It consequently follows that when the lines of magnetic force are parallel, the strength of the magnetic field is uniform.

Couples.—In the preceding investigation the forces acting on the poles of a small magnetic needle are assumed to be equal, opposite, and parallel. Such a combination of forces constitutes a *couple*. The theory of couples belongs to mechanics. We here give some of their chief properties.

1. The magnitude of a couple is measured by the product of either force into the distance between them. This product is termed the *moment of the couple*.

2. When a couple acts on a rigid body it tends to produce rotation, but not to produce any motion of translation.

3. Two couples in the same or parallel planes are in equilibrium when their moments are equal, if they tend to produce rotations in opposite directions.

4. Any number of concurrent couples in the same or parallel planes is equivalent to any single couple in the same, or a parallel plane, whose moment is equal to the sum of their moments.

When a simple magnet is placed in a uniform magnetic field, it is acted on by a couple proportional to the magnetic moment of the magnet, and to the strength (or intensity) of the magnetic field. The magnitude of this couple will vary with the angle the magnet makes with the lines of magnetic force, being greatest when the lines of magnetic force are at right angles to the magnet, and vanishing when the magnet is parallel to them. Conversely, the moment of a magnet is proportional to the moment of the couple which acts on it in a magnetic field of known intensity; hence, it follows (from the principle No. 4 above) that the magnetic moment of any number of parallel magnets rigidly connected together is equal to the sum of the moments of the component magnets. The necessity for the component magnets being parallel is obvious, for otherwise the angles they make with the lines of magnetic force would not be the same. Hence, the magnetic moment of any bar magnet is equal to the sum of the moments of all the elementary magnets of which it is composed. The magnetic moment of any bar magnet is therefore a definite quantity which may always be experimentally determined, however the magnetism may be distributed in the magnet.

To Compare Two Magnetic Fields.—If a magnetic needle be disturbed from its position of rest it will vibrate; and if the lines of magnetic force are sensibly parallel, it can be shown that the number of vibrations per minute are, for any given needle, proportional to the square root of intensity of the magnetic field. Hence, if a needle vibrates n times a minute in the field A, and p times a minute in the field B, then the intensity of the field A is to the intensity of the field B as n^2 is to p^2.

To Compare the Magnetic Moments of two Magnets (Fig. 5).—Let N S be the poles of a magnet, and let N C = C S. Let P be the north pole of a small magnetic needle, placed so that P C is at right angles to N S. Then N repels P in the direction N P, and S attacks P in the direction P S. If a be the strength of one of the poles of the magnet N S, and b be that of the pole P, then the magnitudes of each of the preceding forces will be $ab / (NP)^2$. The resultant P A of these two forces is parallel to N S, and equal to $[NS / NP] \, . \, [ab / (NP)^2]$. Let m be the magnetic moment of the magnet N S, then the force which N S exerts on P is $mb / (NP)^3$. In this expression, the strength of the magnetic field produced by N S at the point P, is represented by $m / (NP)^3$; and this is equal to $m / (NC)^3$ nearly, if N C is great compared with N S. Thus, keeping N C constant, the magnetic moments of two magnets may be compared by finding the comparative intensity of the magnetic field produced by them at P.

In order to do this practically, the effect of the earth's magnetism must be eliminated. This may be done by placing N S parallel to the lines of the earth's magnetic force. If N S be placed in the direction of an ordinary magnetic needle, but with the N pole towards the south, the lines of magnetic force produced by N S at P will be concurrent with those due to the earth. Hence, we may compare the strength of two magnets as follows. The number of vibrations of a small magnetic needle under the influence of the earth's magnetism alone is first observed. Let this be n. The number of vibrations (p) is next observed, when the magnet A is placed as above described, and the needle is at P. Finally, the number of vibrations (q) is observed, when the magnet B is placed in the same position. Then we have the proportion—

$$p^2 - n^2 : q^2 - n^2 :: \text{moment of A} : \text{moment of B}.$$

Gavin J. Burns, B.Sc.

KEY CHARACTERISTICS IN PIANO MUSIC.

[21772.]—When one is in the wrong, I believe the proper course to be pursued is to take the earliest opportunity to acknowledge it, which I hereby do with regard to my statement that the white and black claviers are unequal levers as they appear in the piano, and of course, designating the difference between them as "palpable" was founded in error. For I find, on careful inspection, that the fulcrums of the black claviers are set farther back than those of the white, and on measurement and calculation, both levers seem equal to a fraction. I therefore beg to offer my fullest apology to Mr. Child for anything I may have said hurtful to him while under such erroneous belief.

But while admitting having been wrong in the particulars stated, I am still under the impression that it is to the mechanical inequality of these levers, as fingered in certain cases, that Mr. Stoney attributes the characteristics, and my first reply to Mr. Oliver was probably pretty near the truth as far as it went. What I wish to convey now is that though the levers are equal when each is pressed at its extreme end, in fingering in some of the keys, the fingers will be so grouped that the white claviers will be pressed down at a considerable distance from the end, and as the fulcrums of the white are so much nearer than those of the black, it is the white claviers that thus become less powerful and quicker in action. Of course, I do not attempt to give the reason why this quicker action on the strings should produce any different quality in the tone produced—that I should expect to be treated in the paper on the subject, if my hypothesis of Mr. Stoney's theory be correct. Being now about to start on a trip that may occupy some weeks, I wish to make *l'amende honorable* before seeing the next "E.M.," which is to appear to-morrow, and I hope on my return (if some other correspondent does not do so in the mean time) to refer to Mr. Stoney's paper, if possible, and give more definite particulars of his views, whatever they may be.

August 30. **Captain Cuttle.**

[21773.]—The discussion on this subject has much interested me, and I am tempted to say a few words, as it seems to me that your contributor, "Capt. Cuttle," has gone wrong in his views as to the cause of the difference in effect of the various keys; for this reason, that the mechanical effect of a lever does not in any way depend on the absolute length of it, but on the position of the fulcrum relatively to the two ends. If therefore, two levers of unequal lengths have their fulcra so placed that their two ends bear the same ratio to each other, their mechanical effect is exactly the same.

In the organ this question of mechanical effect is entirely eliminated, as each pipe sounds by the opening of its particular pallet, and it cannot in the least matter by what means it is opened. Yet the different effect of the various keys is exactly the same on this instrument (when equally tempered) as it is on the pianoforte. This fact alone (which cannot be disputed) seems to me to demolish "Captain Cuttle's" position utterly, and, apart from this, if he will open his piano, take out two keys and carefully inspect and measure them, he will find two things: (1) That both keys are weighted on their inner ends to precisely the same amount, and (2) that in the black key, the length from the sticker at the back to the pinhole bears exactly the same proportion to the length from the pinhole to the front end, as in the white key; that is, that, regarded as levers, they are similar in every respect and precisely the same in mechanical effect. For my part, I can see no more reason to doubt that the differences existing under the equal temperament are due to that system, than there was to doubt that the very startling effects produced under the unequal temperament were due to *that* system and to nothing else. **H.**

FREE REEDS.

[21774.]—The letter which appeared on p. 603, by Mr. N. E. Child, does not eventually contradict the statements put forth by me on p. 580, which I will endeavour to prove. Mr. Child says (p. 603) that "I see one of your correspondents imagines (for it is obvious he does not speak from experience) that the shape and position of the tubes necessitates voicing." I am fully aware that this remark is intended for me; but Mr. Child's assertion that "he does not speak from experience" is false, as I am prepared to say that I have actually tried the experiment, and I am quite convinced that the tubes, if made to a certain size and form (according to the tone required), do greatly influence the character of tone emitted from the reeds, whether they are voiced or not; but, I may add, that under the conditions with which I have tried the experiments, voicing the reeds is not in the least required, or in any way necessary, simply because the shape and size of the tubes, and also their position on the soundboard, had all the desired effects in the various sets of reeds, of producing characteristic tone. I have nothing to say against voicing the reeds, only that it is an art in which very few excel, as it evidently requires great skill, practice, and judgment, in order to produce any really good results. As Mr. Child, p. 603, fails to understand exactly what I mean on p. 580, I will put it somewhat plainer for him. I maintain that when all the tubes are made to one scale, it does not influence the tone. What has to be done, then, in order to produce characteristic tone in the various sets of reeds? All that can be done in this case (which is a general one, but not without a few exceptions) is to voice the reeds according to the tone required. This "all" is something almost, if not altogether, beyond the usual skill of any amateur. I have proved its difficulty of accomplishment in many instances myself. Even with thorough practical reed organ manufacturers, the difficulty of voicing reeds to produce true characteristic tone is exp enced. This, no one will deny; in fact, i already universally proved by the fact that th are hundreds of reed organs made and sold that not possess true characteristic tone in the vari stops. Of course, I do not refer to mechan stops, such as the vox humana, tremolo, or fo stops. Voicing the reeds does not affect the r chanical stops in any organ. I must inform Child that I have read the letters referred to; bu do not find in them anything contradictory to statements made by me on p. 580 of the last volu I must also inform Mr. Child that my statem do not refer to harmoniums at all, but to inst ments constructed on the suction principle, such those known as American organs. The refere made to Mason and Hamlin's orchestral organ Mr. Child does not prove me in the wrong at simply because that organ is constructed on a ferent principle to the ordinary American org which contains the exhaust bellows, the orches organ being furnished with a pressure bellows in the harmonium. My statements with regar the influence of the tubes on the tone applies to organs constructed on the suction principle. have nothing to say regarding the influence of channels on the tone, in harmoniums or org with a pressure bellows, as I have not tried experiments with such instruments; but I alw like to see any correspondent state his opinion these matters, if from practical experience. If f any other conditions, or from a mere theoret point of view, I allow it to pass aside as s unless I can find some good grounds to contra any such statements. In conclusion, I should to refer our readers to the remarks made "Organon" on reed voicing (p. 581), the diffic of which is nicely explained when that gentle says that "the operator will have some little di culty in getting the original tone back again." have previously been writing for the benefit those who, like myself, have experienced the d culty of voicing the reeds to produce true char teristic tone. I can voice reeds to a certain ext but I can rarely or ever do it to my own satisf tion. Men of far greater experience than which I have had, have given it up in despair; however, I intend to persevere in the art as o as I can get the chance, although I know of ot means to obtain characteristic tone; but, I admit, not quite so perfect as that obtained really good and skilful voicing. **G. Frye**

THE FLUTE.

[21775.]—Messrs. Rudall, Carte, and publish a book on the construction of the fl by Theobald Boehm, the inventor of the cylin flute, with parabolic head joint, and I wo recommend all those of "ours" who would lik make their own flutes, clarionets, &c., to obtain

At the same time I, like "E. P." (letter 217 would be glad to see a good article or two on th subjects in these columns; for, judging from queries which appear from time to time, th seem to be a goodly number of "our interested. **Old Blow Hard**

CLARK'S IMPROVED DIAMOND HIVE.

[21776.]—I am glad to find that my letters s likely to induce others to give descriptions of v ous systems of constructing movable frame hives. The first who has done so has given which is entirely new to me, and which seems t known as the "Diamond Hive." Mr. Clark m tions three serious objections to this hive, as usu constructed, and which, he says, his improvem have overcome. The one fault which he finds the ordinary bar-frame hive being the drau round the ¼in. passages at ends of frames, which, he says, does not exist in his hive.

Mr. Clark says, "The accompanying draw will explain themselves." Now, I have had a g deal of experience in making working drawi and in working from drawings, yet I must say I do not quite understand these. At first sigh the drawing of frame I thought that I underst it at once, my idea being that the projectio corner of frame marked 2¼ by 1½ was equivalen wide shoulder of ordinary bar-frames, and that small piece at right angles to it marked ⅜in. intended to keep the frame out from the side hive, and give the bees a passage round the fram but though I cannot make anything else out of drawings, I think I must be wrong, as this wo leave a ⅜in. passage and consequent draught, entirely do away with the benefit proposed to derived from this system of construction. Ag in the description, Mr. Clark says: "The fra are supported by two arms, 11½in. long by 1 wide at upper shoulder, kept off from the hive s by ¼in. slips inside same." This seems to pro a passage of ¼in. between the frames and the s of hive; but as the absence of such a pass seems to be the essential feature of this system hive construction, I suppose I must be wron this also, though I cannot make anything else out of the description. I am also inclined to think that I must be unable to understand the matter rightly, because, according to the only meaning I can make out of the drawings and description, the measurements as given in each do not correspond with those given in the other. There are also some other things in the drawings which I cannot understand. There is a board projecting from the front, and I am entirely at a loss to know whether it is the roof of a porch, or a movable hinged-shutter to close a pane of glass, which may be indicated by a quadrilateral figure in the front of hive just above it; then what is the other quadrilateral above that again? and the other near the bottom of the front, and the small object below that? And how are the entrance, flight board, and porch (if there is any) managed?—all of which are items of some importance.

I understand the way the double tiers of sections are put on the hives, and am sure that the bees will take to them very readily—more so than, in some instances, they will to sections in crates placed over the frames in ordinary hives, but not more so than to those placed in frames close behind the brood nest in the improved combination hives. There are other things which require to be explained in this hive; there is a line and some dots in the upper corner of frame—what are they? how is foundation put into those frames? There are also a few other questions which it would be instructive to have answered: Were the hives mentioned, which were only one eighth of an inch thick, in which the colonies of bees wintered so well, diamond hives of the old construction, or were they "Clark's Improved Diamond Hives"? were they bar-frame hives in which the bees succumbed, and those in which they were a fortnight late in swarming, double or single, and were any of them only an eighth of an inch thick? how many of each kind were there in the apiary in which they were under equal conditions as regards situation, food, &c.? (which I suppose includes original strength of stock). Also how long has Mr. Clark been using his improved diamond hives? how many stocks has he had in them each winter? and what were the results obtained from them in honey production each season, and this season in particular?

I hope very much that Mr. Clark will give a farther explanation of his hive, with a cross section showing frame and sections in position, and giving height and thickness of sides, &c., and that he will kindly answer the questions which I have asked. I really ask for information, as I am quite sure it would be a great matter to get rid of the draughts caused by the passage round the ends of the frames, if it could be done without counterbalancing disadvantages; and I would be glad if the subject were discussed in the "E.M." by those who have had practical experience of wintering bees in differently-constructed bar-frame hives.

I would most strongly recommend anyone who has bees, or intends to have them, to get and read up the "British Beekeeper's Guide," by Cowan, published by Houlston and Sons, Paternoster-square, price 1s. 6d.; and also "Wintering Bees," by same author, price 3d.; published by the British Beekeepers' Association. No one should attempt to go in for bees without having those two books and reading them, and really marking them up carefully. "Modern Beekeeping," recommended some time ago in the "E.M.," was a very good book in its day; but, though said to be a new edition, "revised and enlarged," and having the date 1882 on its title page, it is very much behind date, and the B.B.K. Association, by whom it is published, should have it rewritten at once, as in its present state it is in some respects calculated to mislead.

I hope we will get the benefit of the experience of practical bee-keepers; but I also hope that descriptions of hives will only be given by those who have either made or used them, and that the class of contributors who are so fond of giving their ideas and suggestions on any blessed subject which turns up in the "E. M.," which they understand, or think they understand, will "keep their fingers out of this pie."

Finally, as to wintering bees in combination hives furnished with Association standard bar frames, like everything else, there are, at least, two ways of doing it; but I think that anyone who will read Mr. Cowan's little tract mentioned above, will be convinced that, if done the right way, it can be done safely, well, and reasonably easy.

G. J. H.

ALUMINIUM PLATE REACTIONS.

[21777.]—The correspondence on the above subject, published on page 604, letter 21761, calls, I think, for a few words of comment from myself.

In the first place, let me say that the substance experimented on was *not* chloride, but sulphate of zinc; not a bad sample either, being much more free from Cl in fact, than the portion so kindly sent me by Col. Ross, for while mine gave no indication of Cl with the silver nitrate test, the other sample showed its presence very perceptibly under like conditions.

I think it necessary to say this much, in order to prove that in my case Cl had nothing to do with the failure of the plate. This failure, from subsequent trials, I am now satisfied was entirely due to the plate itself, but whether through impurity, or insufficiency of substance, I am not prepared to say. I hope shortly, however, to obtain a piece of plate of the *exact* dimensions specified by Col. Ross, from the dealers he recommends, Messrs. Johnson and Matthey, and will then be glad to report results. In connection with this, I would suggest that if Col. Ross would give the *thickness* in parts of an inch (length and breadth being already so given), he would confer a favour on those of his students who have to obtain their supplies by post.

With respect to the statement that "the chloride is the only salt of zinc which melts in its water of crystallisation," I think Col. Ross is in error. When we consider the formula of zinc sulphate $(ZnSO_4 + 7H_2O)$, it is scarcely to be wondered that it should, as I stated, "fuse in its water of crystallisation." But this "aqueous fusion" must not be confounded with "igneous fusion," which is a very different thing.

Barnsley. **J. Tomlinson.**

P.S.—Permit me to tender my warmest thanks to Col. Ross for the kindly manner in which he replied to my letters, and for the trouble he has put himself to in the matter.

TRANSFER OF THOUGHT.

[21778.]—I agree with your correspondent, "F. W. H.," that the phenomena of Spiritualism, &c., &c., are now being attacked at the root by men like Haeckel and Buchner; but I daresay the majority of the persons who delight in spiritualistic performances are scarcely "advanced" enough to follow the great German scientists. They prefer to amuse themselves by trying all sorts of childish experiments in dark rooms, and fondly believe that they are "investigating the phenomena." At the same time, some cases of thought transfer may be possible from a physical point of view; and I would like to refer "F. W. H." to my letter No. 21624, page 457, in which a theory is suggested. A connection *might* be established between two brains by means of the luminiferous ether. I do not think this is at all probable—in fact, it is most unlikely; but still it is possible. At the same time, thought transfer is not by any means a scientific fact so far, and I am very much disposed to be sceptical about it. **Wm. John Grey.**

Elswick Science School.

[21779.]—I do not quite see what bearing the matters mentioned by "F. W. H.," 21747, p. 602, have on this subject. True, the foundation of all spiritualism is attacked by various students of natural science. What of that? The attack is not a destruction, nor can it ever affect in any way the foundations of spiritualism. Of course, by spiritualism I do not mean the alleged phenomena of mediums and so-called spiritualists, but the belief in the spiritual nature of man, or in anything apart from matter. No amount of materialistic attack or evidence will ever affect this belief or disprove it, though it may destroy the faith of individuals. The belief itself is founded upon faith and inward convictions, and, therefore, is unassailable.

The spiritual idea is, in fact, wholly independent of the material, though coincident with it. Thus such circumstances as the loss of intelligence as the body wears out in no degree whatever *disprove* the existence of the distinct spiritual essence. If a workman is deprived of his tools, his power of work is lowered; if the scientific experimenter is shut out of his laboratory, he cannot work; to come even nearer, if a cataract forms on the eye, the man loses sight though his brain and optic nerve remain perfect. If the spiritual essence exists, it is still certain that in this state of existence it is absolutely linked to, and operates only through, the agency of organised matter. Therefore, no mere study of the actions of organised matter, no effect of the failure of the organs, at all touches the question of the existence of the agent of which these are admittedly the essential tools.

In other words, the fact that the supposed spiritual agent can operate, in a material world, only through matter, does not touch the question of the existence of such an agent, independent of matter, in another form of being. That subject belongs to a wholly different order of evidence and argument, which, of course, is not suitable to these pages. Nor has science anything to do with the matter, any right to meddle with it, or any power to pronounce upon it. **Sigma.**

THE PANAMA CANAL AND THE GULF STREAM.

[21780.]—In letter 21752, your correspondent anticipates a terrible fate for Western Europe. This, I am aware, is not a new idea, and the objection was raised some time ago by the opponents of the Panama Canal scheme. Yet, in spite of that, the canal is to be made, and the nations of Western Europe are calmly looking on at the sealing of their death-warrant. Now I seek for information. What is the course selected for the canal? What will be its dimensions, and through what geological formation will it pass? But, above all, how long will it probably take the Gulf Stream to bore a way for itself sufficiently wide to appreciably affect the climate of our country? We know what immense periods of time have been occupied in making even small differences in our own coasts, even where the cliffs are of soft materials; and I think we may ease our minds of any fear of our nation's destruction. Other and much greater changes are likely to take place quite as soon; and if we are to be alarmed now by the fear of what may happen ages hence, we had better liquidate our national affairs and emigrate *en masse*. But, joking apart, I should like to have the particulars of an undertaking so important commercially, at least.

Salvo Jure.

[21781.]—None of the direful consequences foretold by Patrick Gannon (21752, p. 602) are possible. I guess he has never seen the Gulf Stream, and I have several times. If he and other timid folk will just consider that this stream is a body of water so great as to affect the climate of vast regions, and of such power as to find its way from the tropics to Norway, they may see that the effect upon it of the Panama ditch will be comparable to the waste of water from a ½in. pipe upon the reservoirs supplying London.

If any eroding effect were produced—nay, if any current at all were to be set up by the expected action, the entrance to the canal would have to be guarded by gates, or else the traffic would only be possible in one direction, and that have to be effected in great danger.

The Gulf Stream is only very slightly due to the rotation of the earth, because the water itself is impressed with the motion just as much as the solid earth; it results mainly from tidal action and the easterly trade winds. **Sigma.**

THE SYMBOLIC REPRESENTATION OF FEET AND INCHES—A SUGGESTION.

[21782.]—It being undesirable that the symbols used to designate minutes and seconds of *arc*, should become in general use to represent *feet* and *inches*, I venture to place before the readers of "ours" who prefer calling "a spade, a spade," instead of by any other name, a suggestion which I think will meet with their approval;—that is the approval of those who prefer using symbols instead of the abbreviations *ft.* for *feet*, and *in.* for *inches*; though no doubt many, like myself, prefer the abbreviations in place of symbols. I may here say that the use of the symbols ′ and ″ for feet and inches always puts me in mind of those members of the Asiatic Society, who persist in styling themselves "F.R.A.S." instead of "M.R.A.S.," thus leading one to imagine they are Fellows of the Astronomical, whereas they are members of the former Society

If symbols are to be used for linear measure—and from the frequency with which one comes across them it would appear that they are to be made use of—then by all means let them have a distinctive character from those which by right and long usage are commonly recognised as representing a different kind of measure, and thus put an end to the confusion to which one is liable when reading an article in which the same symbols are employed to designate both *linear* and *arc* measurements.

The English foot being based upon the length of the human foot—hence its name—I would suggest that the character π, which is the first letter of Greek word *pous* (the *foot*), and δ, the first character of the word *dodekatos* (the *twelfth*), should be substituted for ′ and ″ to represent feet and inches respectively. Thus for 10ft. 6in., and 6ft. 10in., we should read—

$$10\pi.\ 6\delta.\ \text{and}\ 6\pi\ 10\delta.$$

respectively, instead of 10′ 6″, &c., which is the absurd fashion now prevailing.

Dalston, E., Sept. 3. **B. J. Hopkins.**

THE PARKER-SMITH BRAKE.

[21783.]—Your correspondents, "Imprimatur," "H. S. J.," and Mr. Parker-Smith, page 603 of last volume, appear to be of opinion that the *only* reason why this brake does not fulfil the necessary "conditions" is "that mineral trucks are run between the engine and the passenger coaches." This, however, is not the only cause.

The Board of Trade Return, and also your correspondents' letters, show that this brake is fitted to but *three carriages* and not to any engines: it, therefore, follows that even if the "mineral trucks" were to be removed from the train, the brake would not then fulfil the "conditions." As it is not fitted to the engine, it could not be self-acting upon the engine in case of accident, nor could the engine brake be under the control of the guard

Mr. Parker-Smith states "that he can obtain simultaneous action throughout a train, whether it be long or short." At present the correctness of this assertion cannot be proved, as only three carriages are fitted. I trust that at no distant date sufficient vehicles will be in use to practically test the question. I have seen experiments made with various forms of "chain" and "mechanical" brakes, in which the brake force is not transmitted through the continuous connections, yet in not one single case have I found "simultaneous action," or even any near approach to it. The advocates of the Heberlein brake state that theirs is the most perfect of the "mechanical" systems, yet we know from practical experiments on English railways that it cannot act simultaneously. I know from experience that mechanical brakes do not work well on trains of ordinary length, and I fail to see any reason why the Parker-Smith brake should be an exception to the rule.

In conclusion, I must remark that nothing in the letters of your correspondents alters the plain *fact* that in the Board of Trade Returns the Parker-Smith brake is stated *not to* fulfil the necessary "conditions." At some future time it is possible that improvements may be made in the details. This is not, however, the subject now before us. To estimate the value of any appliance, we can simply deal with the question as it is at the present time. It should also be remembered that, although many engineers have inspected this brake, *no other* companies adopt it. **Clement E. Stretton.**

Brighton, September 1st.

LATHE MATTERS—PHOTOGRAPHY—OPTICS—VARIOUS.

[21784.]—There seems a strange apathy on the part of our most valued contributors, with the exception of one or two; I have nothing of value myself to send, but I write in the hope of moving somebody, though it be but to kick me.

First, then, when "J. K. P." says that in tapping cast iron it is better to leave the rounded part out of the question, does he mean this literally—that the holes should be bored *at least* ¼th depth of thread larger than the theoretical size? Also, taking average workmanship, what difference would he allow for other materials—for Whitworth threads? Can he tell me if gas thread should be rounded and of same angle as Whitworth, or not? Also, is it good practice, or rather the reverse, to let the tap act somewhat as a reamer?

A friend of mine just back from Germany declares he saw at Heidelberg, among the antiquities dug up in the castle, and now in the museum, a large screw tap of rough make, perhaps 8in. or more long and 3in. diameter, with threads of 5 to the inch, or thereabouts. Is this likely to be a genuine antique?

Daguerre's monument seems to have produced a capital crop of scientific "croppers." Let me add to those on page 599 the statement in another daily, "Herschel's discovery of the use of hyposulphite of soda in *developing* the image, &c." Please, somebody, give all the instances of use of hypo as a developer?

Will "O. V." kindly say if the subject of spherical chromatism is anywhere mathematically treated, or if he is the first to bring the matter to the notice of theorists? I can't help fancying that mathematicians tacitly assumed (or accepted) that altering the character of curves would seriously affect the balance of spherical aberration, and would produce but small effect on colour, whereas it would seem that having destroyed sp. ab. by proper ratios of *radii* we may sometimes play considerable tricks with the nature of the curve. Practical men do not as a rule seem to have known where theory was wrong (eh, "Prismatique"); but to have found out by rule of thumb a way of correcting the error. I suppose I ought to except Gundlach, though. In old days lenses were supposed to be ground to spherical curves, and if the curve were altered, it was not intentionally so, but in the ordinary course of manufacture. In an old book I once read that out of the same two kinds of glass a number of lenses were ground *exactly* (?) alike, and to such spherical curves as theory dictated (so that any one crown, and any one flint, taken at random, should have given a good glass), but that, in practice, a flint was tried with each of the crowns in turn, till a suitable match was found. The writer gave no reason, but apparently assumed that the difficulty of getting correct radii made the large stock and process of trial necessary. One can hardly suppose that the great makers of large glasses worked in this way, and smaller men made but small glasses or bad ones. This extract is but of small value; but as bearing on the question of retouching, I send it for what it is worth. The work was an expensive one in its day, a day so long ago that chlorine water was a new discovery and called oxymuriatic acid.

Will anyone tell me how large circles, as transits and mural circles, are divided? The tangent screw method seems inapplicable, and if the circles be on the cylindrical surface, and not on the flat face, *beam compasses seem inapplicable* also. I can only *suppose* that an accurate tangent wheel is attached to the circle concentrically and moved by a train of wheels, as in "J. K. P.'s" dividing engine.

Did "D. H. G." ever see an article by Mr. [illegible] *Rose*, claiming to write Q.E.D. to the proposition "that it is necessary to assign definite angles to lathe tools?" The article was in a back vol. XVI.–XXV.; but I have never seen any reference to it, so assume our friend either disdained to reply, did not notice it, or, worse still, accepted the reasoning as conclusive. Among many others which my modesty has made me keep back, I have a letter in my desk, months old, which I shall have to sling at the mechanical giant if better champions won't come to the fore.

About that screw question, too, why do not some more of our practical readers take it up? Holtzapffel's screws are perfect for this purpose, and are so widely in use that they are a standard. That they will not "live" is certain: but certain people are anxious to kill them as soon as possible.

Why won't "J. K. P." give us a few articles on the subject, telling us what threads are in use, what ones may be dispensed with, and how we may best aim at simplification? Surely, angles of 45°, 50, 55, 60, and 90, are not all necessary.

Dr. Edmunds says in a back letter that his thread is *rooted* (or some such word) more strongly on its shaft than Whitworth's. There is a sense in which this is true, but I don't think he means it: and I should be glad to know what he means. By the bye, Dr. Edmunds is very fond of the question, "In what respect are H. and Co.'s threads better than mine"? Did it never occur to him that for him to ask the question is somewhat what boys call "cheek"? When a man comes and asks us to destroy goods of a well-known pattern, proved to be good, to throw aside valuable property, and substitute more of a new design of his own, and at considerable cost, it is for *us* to ask *cui bono*; and if Dr. Edmunds is asked in what respect his own thread is superior to H. and Co.'s for die-cut screws, of short length, used as "cement," he would have no very good answer. He must not think I am against action; I am only anxious that any change should tend towards a simplification of screw standards, and that the decision should not be hastily arrived at and require revision later on. Any new thread should displace not one, but, if possible, several old varieties.

A little time back there was an article (American?) on the proper longitudinal section for lathe mandrels, arguing that they should be somewhat of an elongated (very) egg-shape. Has no one anything to say on the proportions and materials of mandrels? Holtzapp., in Vol. IV., is meagre.

Dr. Edmunds's proposed mark on the nose will have one decided good result—the user at once will see if the chuck is screwed home, or if dirt or other obstacle is in the way. Will it have any other good?

Who is responsible for the punctuation in Holt., Vol. IV.? It is perfectly awful.

Will Martin or Greenwood say how they obtained the size of "tapping" hole in their tables—by turning down a bolt, by measuring a drill, or by calculation to the nearest 64th? Also, do they recommend these sizes for cast iron, or what? I have been going through their tables, and have a reason for asking.

I fancy I am outstepping my limits: but if I can only draw one or two letters, our readers will be grateful. **Bow.**

ORNAMENTAL TURNING AND MANDREL NOSES.

[21785.]—I am pleased to see Dr. Edmunds's letter on "Ornamental Turning and Mandrel Noses" in this week's "E. M." From what information I have at present, I am not able to decide either diameter, shape, or pitch to make the nose of mandrel to a lathe I have had in hand for some time. Shall I be asking our friend Dr. Edmunds too much if I request him to give us in the "E. M." the same information that he has given to the A. M. Society; also a drawing of the nose of the mandrel he advocates? I am sure it will be highly valued, and perhaps it may be followed with the replies and conclusions of the members of the above society. I myself wish to complete my lathe with all the advantages I possibly can, and of course it will be a great one to have mandrel nose a standard size pitch and uniform with other amateur lathes. I would gladly buy the number published by the A. M. Society (I have bought some): but as I am a poor man, with other calls for all I can do, I am reluctantly compelled to confess I cannot afford them. Besides, what better place can there be for this subject than our "E. M."? This I have taken from the commencement. However I may have been pinched for twopence, I have always found it possible to get my paper, and I cannot sufficiently say how grateful I am for the information and pleasure I have derived from it. Our contributors cannot tell the good they do, and the pleasure they give to their brother readers who may be poor and sadly in want of the information they are able to give. I seldom trouble our Editor with letters, but I must give my tribute to the good the "E. M." has done me, the many happy hours I have spent over it after my day's work, and also my thanks for the teaching I have received from my brother readers.

By the bye, our Editor must excuse me—but I must tell it. I went on Friday last for my number, and my bookseller said (a retired certificated schoolmaster), "I have just been looking over your "E. M.": there is a lot of stuff in it, but I should say of no use unless you are specially trained—educated, I may say—to understand all these scientific subjects." I said, "You must understand I have taken it from the first number." And the thought struck me, *all these eighteen years, unknown to myself, the "E. M." has been educating me*, so that almost every subject contained in it is more or less understood.

Some time back I asked one of our readers to give some information on the lathe; but he said that he had sent the information to the A.M. Society *for* publication, so could not accede to my request. I was much disappointed, but I hope our friend Dr. Edmunds will see his way to satisfy us regarding this matter. I am afraid that I am presuming too much on space, but I want to ask another thing, and that is how am I to get the exact measure of an inch, or fraction of an inch, in making my lathe nose? I have used a rule all my life almost, and anybody who has done the same knows the difficulty in getting an exact inch from the same. I will be bound in our shop, of from 50 to 100 men, you will not get half a dozen rules the same length. Supposing I wished to make the nose of my lathe to take the same chuck as Dr. Edmunds's lathe will take, can he tell me how to get my standard to measure from (so that he might lend me a chuck or I might lend him one for any particular purpose)? If this is to be done by having a female gauge or standard to fit the lathe nose to, then I can understand; it will be easy enough, but every workman will see the difficulty of chasing a screw to fit a chuck which he has not got to try on. **A Worker.**

PARALLEL STRAIGHT LINES.

[21786.]—Perhaps you can find space in your columns for the following remarks on parallel straight lines.

Euclid's treatment of the subject is less satisfactory than his treatment of other matters. His well-known definition of parallel straight lines, although good as a definition (since it accurately describes the thing defined and excludes all else), involves the use of a tedious and not at all obvious axiom. The general principle in mathematical reasoning is to do with the least possible amount of assumption. This principle is rigidly followed by Euclid. Many of the propositions demonstrated by him are far more obvious than this axiom. For example, any two sides of a triangle are together greater than the third (I. 20) and others.

Various methods of treating the subject have been advocated by different writers. Speaking of these methods, Mr. Todhunter remarks:—"Speaking generally, it may be said that the methods which differ substantially from Euclid's involve, in the first place, an axiom as difficult as his, and then an intricate series of propositions; while in Euclid's method, after the axiom is once admitted, the remaining process is simple and clear."

The following definition obviates the use of a special axiom. Parallel straight lines are such as are in the same plane, and make equal angles with the same fixed straight line.

The angles must, of course, be measured on the same side of the fixed line and on corresponding sides of the others. In other words, they must be the exterior angle, and the interior and opposite angle of props. 28 and 29. There seems no objection to the above definition. The property used is as obvious as that used in Euclid's, and the different props. are as easily deduced from it. It involves the idea of a straight line as direction, and that direction as measured by the angle made with a fixed line. These notions, indeed, being premised, we might define parallel straight lines as those lying in the same plane and being in the same direction. The property involved in Euclid's definition follows at once. For (Fig. I., 28) let A B and C D meet towards B and D, then exterior angle E G B is greater than interior and opposite angle G H D, which is absurd, since they are equal by definition, therefore A B and C D do not meet towards B and D. Similarly, since from Fig. the angles A G H and G H D are equal, they do not meet towards A and C. The props. are easily deduced from the definition. Thus (Fig. I., 27) if the alternate angles are equal, it follows at once that the exterior is equal to the interior and opposite, and therefore the lines are parallel by definition. Again (Fig. I., 28), the angles B G H and G H D are together equal to the angles B G H and E G B. Therefore the angles E G B and G H D are equal, and A B and C D parallel.

If a straight line fall on two parallel straight lines (I., 29), the angles E G B and G H D are equal by definition, and from this it follows at once a

The success of this balance has been very great, a large number of chronometers having been sold to the Admiralty with balances of this description not only bearing the name of Mr. Poole, but of firms that sold his chronometers, who were anxious to possess a reputation attributable to the skill of this artisan. In 1855, an eight-day chronometer by Lawson heads the list; in 1856 Muirhead, with Poole's auxiliary compensation-balance, and, in 1857, a chronometer by Hornby, with a new description of balance, invented by Mr. Hartnup, of the Liverpool Observatory. From the large number of chronometers sent to the Liverpool Observatory to rate, Mr. Hartnup, by a series of experiments, soon found the defective state of the ordinary compensation-balance for a long range of temperature, and further experiments have induced him to conclude that, for a range of temperature of 30°, this error may be confined to very narrow limits in a well adjusted balance.

The balance I am now about to describe (Fig. 9.) was made by Mr. Wm. Shepherd, a skilful chronometer maker of Liverpool, who, in combination with Mr. Hartnup, agreed that the result of their experiments should be made known for the benefit of the public. The results of the discussions with Mr. Shepherd, who made several trials, were concluded by his making a balance of circular form, so that the laminæ of brass and steel might be turned down to the requisite proportions with facility, and that the compensating and poising might be as easily effected as in the ordinary compensation balance. Secondly, the balance must be so contrived that the compensating rim and weights should move towards the centre with an increasing velocity in an increasing temperature, whilst in a decreasing temperature they must recede from the centre with a gradually diminishing velocity. In the engraving, the rim is composed of a lamina of brass and steel, united as in the ordinary balance, the steel of which is bevelled or turned at an angle of 45° or thereabouts. The bar *a*, *a*, with the bars *a*, *b*, *a*, *b*, and also the bars *b*, *c*, are composed of brass and steel united as in the rim; *a*, *a*, has the brass uppermost, and *b*, *c*, *b*, *c*, have the steel uppermost, and they are firmly joined at *b*, *b*. The compensating weights slide upon the rim as in the ordinary balance. Now the effect of the inclined position of the rim is this: The different expansion of the two component strips carries the weights to and fro from the centre, and also up and down in a slanting direction, owing to the bevelled form of the rim. The slant takes off from the action of the rim, but this is increased to the proper amount at mean temperatures by setting the weight more forward, so that the balance is compensated for small changes. So far the new construction acts exactly as the ordinary compensation balance. To show how the balance acts in extreme temperatures, first take the case of extreme heat—the ends of the bar *a*, *a*, bend downwards, and the ends of the bars *b*, *c*, curve upwards; and the compound effect of these two curvatures is to set the bevelled rim more nearly perpendicular to the plane of the balance, whence the effect of the compound rim in bringing the weights towards the centre is greater than it would have been in its more inclined position. Now, this tends to shorten the time of vibration of the balance. In the ordinary construction, a chronometer loses in extreme heat; the new construction, therefore, tends to compensate the losing rate in extreme heat. Again, in extreme cold, the ends of *a*, *a*, bend upwards, and the ends of *b*, *c*, *b*, *c*, bend downwards, from the unequal contraction of the brass and steel strips which compose the bar. The effect of this compound action is to set the rim farther or more nearly parallel with the plane of the balance. Hence the effect of the compound rim will be less effective in removing the weights from the centre than in the ordinary construction, and the balance will move more quickly. A balance of the ordinary construction loses in extreme cold: hence the new balance tends to compensate the error.

Mr. Hartnup found by experiments that chronometers fitted with the new balance are sufficiently compensated in all degrees of heat and cold, and the appended tables were given containing the rates of three chronometers to which these new balances were applied. The temperature ranging from [illegible] the chronometers were tested for [illegible] and extreme temperatures of heat and [illegible] with scarcely any variation. These [illegible] were afterwards tried at [illegible] No. 25, Wm. Shepherd, was purchased by the Government. [illegible] 1857, was tested in [illegible]. In 1858, a chronometer [illegible] heads the list with a new [illegible] with auxiliary compensation [illegible] and third with a range of temperature [illegible]

[illegible] Liverpool [illegible]

In 1860, a chronometer by Birchall stands first, with an alteration of the balance [illegible], W. P. Birchall second, Muirhead with Poole's auxiliary, third, with a range of temperature from 25° to 100°.

In 1861, McGregor, with Poole's auxiliary heads the list, Webb second and third with an unexplained auxiliary to the balance: a range of temperature from [illegible] to [illegible].

In 1862, two chronometers with Kullberg's balances, the first one bearing the name [illegible] and Roberts, the second one the name of the maker, Mr. Kullberg, the third, fourth and fifth chronometers were with Poole's auxiliary compensation: range of thermometer [illegible].

In the year 1863, a chronometer by Fletcher, with auxiliary compensation, heads the list, Kullberg second, Webb third, the temperature ranging from 35° to 97°.

In the year 1864 a chronometer by Kullberg first, McGregor second, with Poole's auxiliary: range of temperature 32° to 97°.

In 1865, a chronometer by Webb first, Lister and Son second, with Poole's auxiliary, Dent third: temperature 32° to 101°.

In the year 1866, a chronometer by McGregor stands top of the list, Cairns second, Poole third, all with auxiliary compensation: temperature [illegible] to 101°.

In 1867, a chronometer by Sewell heads the list, Gowland second, with auxiliary compensation: range of temperature from 30° to 95°.

In the year 1868, Birchall first, Fletcher second with auxiliary compensations: temperature [illegible] to 96°.

In the year 1869, Fletcher first, Whiffen second: range of temperature from 39° to 100°.

In the year 1870, a chronometer by M. F. Dent heads the list, Chittenden second; temperature 33° to 95°. The small error of M. F. Dent's chronometer, in this year of trial, was noticed by the Astronomer Royal to have been the finest chronometer that had ever been on trial, it having made but the small error of 5·5 seconds as the difference between the greatest and the least: and 3·8 seconds; the greatest difference between one week and the next, during a range of 62°. No description of the balance having been given in the published rates, the writer supposes it to have had a balance similarly constructed to the one exhibited by this firm at the Exhibition of 1862, of the following description:—M. F. Dent's new compensation balance, with outside auxiliary bows made much thinner than the ordinary lamina of the balance, the steel being outside and the brass within, reversing the metals for the auxiliary compensation pieces or bows; this gives an increased error which the primary compensation is intended to compensate. The general effect of the balance is that the compensation power is greatly increased in high temperatures. The outside bows are quite free from bankings or check pieces acting upon the balance, which is the principal objection to compensation pieces.

In the year 1871, a chronometer by Charles Frodsham heads the list, with a new reversed balance, performing very nearly equal to M. F. Dent's chronometer in the previous year; temperature ranging from 36° to 94°.

In 1872, a chronometer by Kullberg takes the first place, with a flat rim balance without auxiliary, Hennessy second, McGregor third; these two chronometers having auxiliary compensation to the balance. Temperature 44° to 95°, a range of temperature of 51° only.

In the year 1873, a chronometer heads the list by Wiechert, with Kullberg's flat rim balance without auxiliary, showing the very small error of 3 seconds during any week of trial, and 5·1 seconds as the greatest difference between the greatest and the least. The second was a chronometer by Usher and Cole, Mr. Kullberg's being third; three very fine chronometers! The range of temperature was from 35° to 95°, a range of 60° only.

The balance of Mr. Kullberg is a modification of Mr. Hartnup's and Mr. E. J. Dent's balances, or an improvement on the principle of the balances invented by those gentlemen. It is composed of a compensated disc, the rim and centre bar being all in one piece, thus doing away with the attached centre bars as in the Hartnup balance, and is so constructed that the weights shall act in a straight line to the centre, and has, up to the present time, performed better than any other chronometer at the Royal Observatory, Greenwich. The range of temperature has of late years not been so great, and this accounts for the beautiful performance of the selected few chronometers purchased. This balance does not appear so difficult to make as the Hartnup balance, but it is far harder to construct, and will cost about treble the price of the balance of ordinary construction. How these balances will act in other hands, and in higher ranges of temperature, remains to be seen before it can be said that chronometers with these balances shall surpass all others, as was the case in the last year of trial: the balance with auxiliary compensation performing nearly equal to the first, and surpassing the third chronometer with this new flat disc balance.

In concluding this chapter can give no suggestions for giving the last delicate finish t compensation by any means acting upon the s which for the sake of giving lasting good per ance, must be perfectly free and undisturbe

(*To be continued.*)

[51734.]—In reply to "R. M.," No. 217 think he will find his letter fully answered i *Horological Journal* for this month. "R. requires, how came Berthoud to establis matter of certainty that 312 seconds only daily loss was attributable to loss of elas and 62 seconds to increased length, whi neglected breadth and thickness of the b spring. This question certainly mus answered, thus:—That Berthoud was by his experiments, with a chronomet clock carrying a balance under perfect c and with its spring carefully brought to mea say, at 55° of temp. Fah., its rate must hav carefully taken at the starting point, and labour of love of horological art could have him on for the completion of his task; but "R. M." will read the table of the experi chronometer, by Charles Frodsham, as tri the Royal Observatory, Greenwich, and se closely the trials corroborated with Bert experiments, it is all that I can say up subject.

The late E. J. Dent also tried the same ment with a glass *balance* or *disc*, and att 306 seconds or 5 minutes 6 seconds to a l elasticity of the balance spring, and 1min. 1 increase of length. He also tried the same ments with balance springs made with pall and also with gold. I think it is tim the term "pendulum spring" and "hair s are discontinued as far as the bal concerned, for the term "hair spring" to me an absurdity, and the pendulum is the spring, properly speaking, that the vibration of the pendulum. The balance controls the vibration of the balance, and as should be universally called. As to hair spri Yankees are full of it, so much so that the invented a tool for the removal of the hair Certainly the term has a taint of the barber's about it, and I hope our English watchmake think so, and drop the term, and call it the balance spring.

REPLIES TO QUERIES

◆

**** In their answers, Correspondents are fully requested to mention, in each instance, t and number of the query asked.*

[50981.]—**Hydraulic Cranes for Ship** *Quetta*, belonging to the British India S. N. fitted with hydraulic winches for cargo; &c., worked by a steam pump and accumu the engine room. The chief advantages a lieve, the saving of wear and tear as c with quick-moving steam winches, and s working cargo at night, with passengers on board.—London River.

[51139.]—**Slide Rule Practice.**—The given by "E. E. S." on page 558, last Vo course, correct; but is the D line in suc necessary or convenient? In a tract (no by the late J. W. Woollgar, a simple No. 117, may be seen:

A | Sp. gravity weight
B | 27·73 cubic inches,

and for bar iron we may use:

A | 10 weight lb.
B | 356 cubic inches.

—J. C. H.

[51157.]—**Tonnage of Steamers.**—T *gravia* is 400ft. long, 44ft. 6in. beam, a deep.—London River.

[51157.]—**Tonnage of Steamers.**—Th dimensions of the ss. *Belgravia* should h given as—length 400ft., breadth 44ft. Si 33ft. Thanks to "Brass Finisher" having called my attention to this matter.-

[51190.]—**Dynamo Construction.**— in the commutator ring is diagonal or order that the current may be taken off and continuously.—A. S. B.

[51191.]—**Bricks.**—How can "Brick" obtain an answer to this query, unless f one who has seen the machine and the T. P.

[51198.]—**Bicycle Wheels.**—There i of "telling" anyone how to put in a lo spokes. It is a case of showing.—E. G.

[51224.]—**Telephone.**—If all the st connected, you cannot ring up one witho the others.—Electro-Magnet.

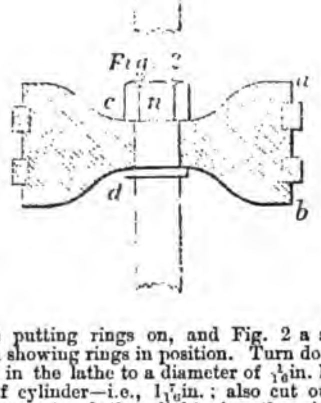
5.]—**Dynamo Machine.**—To Mr. Lan- —My thanks are due to you for so kindly my query (27th July). Will you please me (1) whether the use of 360ft. No. 12 yers) for F.M.'s, and 170ft. No. 16 for Arm. swer my purpose? The R.'s come, I find, t the proportion I mentioned. (2) I pre- should connect magnet in multiple arc. ay yes or no.—A. W. Lambert.

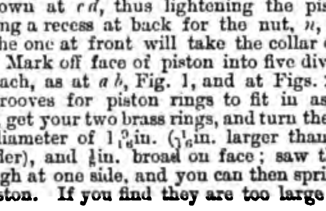
7.]—**Girders.**—The difference between a nd a trellis girder is seen in the following hat in French both are called *poutre en* and in Spanish *viga enrejada*. In Italian, ice is *trave all'Americano*, and the trellis *traliccio*. In German, the lattice is *Gitter-* and the trellis *Fachwerkträger* — i.e., :" means trellis, and "Fachwerk" frame- g. By which the querist will see that the re synonyms; but I think the distinction that lattice applies to iron bridges, and wood; also, that trellis would mean only gonals between two uprights, while lattice nclude many diagonals.—Nun. Dor.

1.]—**Gold Printing on Silk.**—The silk first treated to size—isinglass size preferably hen be printed with gold size on which the aid when it is tacky; or dusted over with powder—which is the usual thing. Neck- not made of silk nowadays; but the best inting is done as above. Better than print- have the letters or designs woven in gold- silk.—C. T.

3.]—**New Zealand.**—Several queries have appeared upon this Colony which do not to be readily answered. With our Editor's ion, I will give the rough impressions I re- luring a 12 months' visit to the colony during On arrival I found that the people did not r things very prosperous. They were g the inevitable period of depression that llow the somewhat reckless spending of the ions borrowed in the English market. s, and nothing but railways, seemed to have e whole absorbing desire; the question of route, or whether they would ultimately munerative, apparently being often totally ded. This condition of things mostly occurs South Island. I much regretted to see that a portion of the loans had been devoted to rnal country roads. Millions of acres are orthless owing to the impossibility of getting . The absurdity of providing costly rail- which mostly follow the coast line) to carry to the ports without the means of bringing luce to the railways, apparently not having 1 to those managing the disposal of the All these things, however, now are re- serious attention. Two experts from l were imported to carry out reforms, and n salaries, which last was no insignificant Space will not permit me to go more into atters; suffice it to say, they are rapidly im- . In answer to "J. B. H.," the "best or wheat and sheep occurs on the plains of th Island, but all of this was long ago p. I understand, however, that many e sheep runs on these plains let se are now falling into the hands overnment; these will be cut up into all ocks for large and small farms, and is t land. Particulars of present prices, &c., doubt be obtained at the Agent General's Westminster. Bush land (that is forest n be obtained in the North Island from acre, sometimes less, according to position. n will contract ordinarily to "fall" at 25s. , and a like sum will sow it down in grass. e the timber is all burned on the ground, has lain some months to get thoroughly The resulting huge charred trunks and s have to be split, heaped up, and re-lit, cess being repeated till all is gone. The are usually allowed to rot, which they do years. The grass seed is sown as soon as nd cools after the first burning, and springs luxuriantly. Fencing is an expensive and ome item, many forms are in favour; but no doubt when you have the timber on the substantial post and rail fence will pay in . A single stretch of barbed wire, to dis- cattle rubbing, will be found a good . A party of young men fond of hard ill find great interest and novelty in this lthough the destruction appears ruthless, satisfactory to note the daily increase to the , generally, at first to let in more sunshine ut or whare (pronounced wharry). Wild d boars can be hunted in most parts, the of birds of all kinds being most abundant. inland the North Island come the tu plains, an immense area; owing e difficulties not much has been done em. As a public company is now ing a railway right through these the native trouble will not long be heir objection is merely a protest on their eir power being gone. These plains are , and though the vegetation is very fair, the ground will not be so productive as the cleared bush land, though on the other hand the time and expense of clearing will be saved. The active volcanic region of Tongariro lies about the centre of these plains (see page 515). Our party attempted the ascent of the volcano, but failed owing to the unfavourable wind blowing the sulphurous fumes down the mountain side. The streams were found to be heavily charged with chemicals, which was not altogether a pleasant discovery, as the sulphurous dust is very thirst provoking. This region is certainly one of the most wonderful in the world. Geysers, hot-springs, mud volcanoes, &c., abound over a large area. One native village we visited on the shores of Lake Taupo seemed to be situate on the crust of an immense subterranean high-pressure boiler, steam and water were escaping in every direction. All cooking was performed by its agency. I also saw two natives busily scraping a pig in a boiling hole, and from the accumulation of hair it seemed to be the usual village resort for this purpose. Potatoes put into the steaming earth were excellently cooked in 20 to 30 minutes. Large pools of every temperature existed, some of high repute amongst the natives for their curative properties; every evening they bathed together, and seemed to enjoy the advantages they possessed for cleanliness. Though my stay in N.Z. was short, I saw enough to convince me that anybody with a knowledge of a definite trade, such as joiners, plumbers, smiths, masons, &c., need have no fear of not doing well in New Zealand. It is the young man of superior education, but without a profession or capital who fails in New Zealand. The demand for bankers' and merchants' clerks is more than supplied; the rest have to work, and very menial work, too, sometimes. The rates for money are just now high—10 per cent. for small sums up to £500. The flow of money to England for machinery and merchandise is extensive; the want of manufactories seeming to be great. Immense sums are annually spent in importing such things as jams, sauces, matches, &c. As regards climate, the country lying north and south, any desired variety may be had, from the semi-tropical of the Bay of Islands to the degrees of temperature experienced by Cornwall or Devon in the south island. The seasons are far more regular than in England. Its mineral wealth is only in the elementary stage of development. Any further information will be cheerfully given. —Imprimatur.

[51301.]—**Metallic Piston Rings.**—I think "Cylinder Bore" will find the following a simple and good method of making his piston and rings, and is same as used for locomotives on Ramsbottom's principle:—Fig. 1 is a plan of piston before putting rings on, and Fig. 2 a sectional sketch showing rings in position. Turn down your piston in the lathe to a diameter of $\frac{1}{16}$in. less than bore of cylinder—i.e., $1\frac{7}{16}$in.; also cut out metal as shown at *c d*, thus lightening the piston and forming a recess at back for the nut, *n*, to fit in, and the one at front will take the collar of piston rod. Mark off face of piston into five divisions of $\frac{1}{8}$in. each, as at *a b*, Fig. 1, and at Figs. 2 and 4; cut grooves for piston rings to fit in as shown. Next, get your two brass rings, and turn them down to a diameter of $1\frac{9}{16}$in. ($\frac{1}{16}$in. larger than bore of cylinder), and $\frac{1}{8}$in. broad on face; saw the rings through at one side, and you can then spring them on piston. If you find they are too large to press into cylinder, file a little of the cut ends, and make them so that you can just press them into your cylinder with the ends meeting. You will find, by making the rings larger than bore of cylinder, that they will have plenty of spring against side of cylinder, having a tendency to press outwards to their former size; and if the sawn ends of the two rings are placed on opposite sides of piston little or no steam will pass them. The rings need no scraping. Make piston rod with a collar on to fit against piston, and a thread at the end to take a nut; and, if you choose, you can drill a small hole through nut and rod, and put a small split cotter through to prevent nut turning.—W. E. G.





[51301.]—**Metallic Piston Packing.**—If the casting which forms the rings is well hammered on a mandrel before turning and boring up, you will find that the rings will expand sufficiently for your purpose after being sawn open. The reason why the rings are best turned up a little eccentric, is that the part which wears must have most metal to spare, and, as the rings usually wear on the side where the saw-cut is, it is best to have the thick part there. I regret that the drawing I sent of the piston shows the groove too deep. It should just be deep enough to allow the thick part of the packing rings to rest against, so as to prevent the steam blowing through to any serious extent. The rings can easily be taken out and examined by simply unscrewing the nut and taking the covering disc off. If the lid of your cylinder is turned out to receive the nut on the piston-rod, you need not fear any serious damage from the nut coming off, for, as soon as the nut gets a little loose when at work, it knocks against the cylinder cover every stroke, and gives warning by the noise.. I have only had one become loose once, and that was my own fault in not screwing it up properly after cleaning. It is a good plan to lighten pistons as as much as possible where the strength is not required, as the weight of the piston, piston-rod, and connecting-rod make a marvellous difference in the speed and wear of the engine when running a high number of revolutions per minute. Don't use solder to fix the piston to the piston-rod—it makes a tinker's job at the best, and solder has not a bit of strength for such a purpose. When the engine is at work the steam seems to take all the holding nature out of the solder, as I have experienced lamentably, and only use it when required where it will not be subject to any heat. While on the subject of packing, I may say that lately I have been trying asbestos fibre as a packing for the piston and gland of a 2in. bore trunk engine on a 5ft. model steamer, and it answers the purpose so well that I intend using it always instead of the usual cotton packing. It reduces the friction considerably, and always keeps steamtight and does not rot.—S. Austel.

[51327.]—**Angular Velocity.**—I am greatly obliged to the correspondents who have written on this subject (by the way, I suppose "J. H." means "Principles of Mechanics," by T. M. Goodeve, M.A., which is reviewed in your issue of the 24th August), but not any give me the information I want. I have, and can get the proper weight for an engine flywheel, or rather, I should say, I have got the weight of wheels that are now actually running, and doing their work well; but some of them may probably be theoretically wrong. Nearly all the writers I have consulted vary in their rules for the weight of flywheels. Let any reader try to get the weight of the rim of a wheel by, say, Molesworth, Burgh, Bourne, and Rigg, and then compare the results. I think he will find them rather confusing. Angular velocity is a term that was not used when I learned my trade, and what I want to know is, is it a shorter way of getting out or calculating the stored up energy of a revolving body like a flywheel, or can the proper weight of flywheel for any engine be got out in less time than by other methods used? Perhaps it will make my question plainer if I give an example from practice:—An engine has an 18in. cylinder, 3ft. stroke, 50 revolutions per minute, 12ft. flywheel, is driving a steady weight with 80lb. pressure in boiler, say, averaging 50lb. on diagram. What weight should the flywheel rim be to carry her round three times after the steam is shut off, all the load to be kept on? I have no doubt it will astonish some of your practical readers to know that the specified weight of flywheel for above was 10 tons, and the rim does weigh $7\frac{1}{2}$ tons.—Tyke.

[51337.]—**Air-Pump.**—"J. W." is right, I really meant air-pump. The pipe recommended should branch out below the air-pump cover and project upwards, say, 1ft. high. If it is an open-top hotwell over air-pump, the pipe can be carried up and turned over into top of hot well, as a means of keeping surroundings dry, as a little water may occasionally be carried through the pipe.—Boswell.

[51346.]—**Clarionet.**—"A., Liverpool," in answer to this question, says "the bell-mouth only increases the loudness," and I take it to mean that it increases the loudness of tone throughout the instrument, and I think it misleading, for if the bell increases the

rt of the instrument, it is the
ir harmonics or twelfths. I am
that even these notes are in-
he bell; but I am sure that they
rpened when I take the bell off.
to the conclusion that the bell
nore to do with pitch than it
r "loudness." So far as the

they give a more regular sound
ugh many in the usual way of
ium would not notice it. There
he steel reeds which I have not seen noticed: they must be polished and blued, or they will rust. Now if you tune them after they are blued you must take this off, and so make them easier to rust, and then if you were to tune very thin reeds you reduce in time their strength and thickness. To avoid all this I melted some wax and rosin to a proper thickness, and melted a small quantity on the end of each reed, and did the tuning by adding to or taking from the composition, thus avoiding meddling with the reeds at all, and found it an extremely good plan.—Edwd. Thos. Scott.

[51425.]—**Ash of Coal.**—Thanks to "A. E. S." and W. E. Haden. I do not wish to have an exact analysis; I merely wish for a general reply, so that I may form some idea of the effect of coal ash on garden soil. For my purpose the coal may be assumed to be what is sold as Wallsend in London, or Silkstone, as those are the principal coals ordered. Sometimes we find large pieces of what we call "slates" for want of a better term, but the great bulk of the ash is greyish white soft substance, the composition of which I wish to know very roughly.—E. G.

[51432.]—**Clarionet or Oboe.**—Of these two instruments, I would recommend the clarionet to "Woster" as the one most likely to satisfy him. Although the oboe is a sweet instrument when well played, it presents difficulties in the management of the reed (the one thing essential for the production of a good tone) which appear almost insurmountable to many beginners on that instrument. If he had a C he would be able to play violin music with a piano; but, solos with accompaniments are written either for B flat or A, and the B flat clarionet is generally acknowledged to be the best solo instrument. Correspondents of the "E. M." who contemplate making these instruments, will not, I am afraid, be very successful. A clarionet with joint close up cannot be sharpened, and when drawn much in order to flatten it, the whole instrument is thrown out of tune. To obviate this a new one has recently been brought out, which, by the action of a slide, shifts all the holes; but I do not know whether it has proved satisfactory. There is one very mysterious wrinkle in the "set" of a mouthpiece. Reeds are made of various thicknesses to suit different players, and if too hard can be refined (or made thinner) by rubbing with "Dutch rush." "J. J. I. D." speaks of a small F clarionet. I have never yet heard of one. They are made in E flat, A, C, and B flats.—Clarion.

[51432.]—**Clarionet or Oboe.**—In "J. W. C.'s" reply to "Woster" (vide p. 608), the former states "the extremely nasal tone of the latter (i.e., oboe) would be objectionable in a drawing-room." Is not this assertion rather too sweeping? I am totally ignorant of clarionet playing (I mean the difficulties, &c., to be surmounted), but have been an oboeist for the past twelve years, and can certainly say that in my opinion, and in the expressed opinion of many others, there is nothing whatever objectionably nasal in the tone when once the proper method of blowing is acquired, and suitable reeds obtainable. About this latter it is a *sine quâ non* that the player makes his own reeds. Very little manual dexterity is required, and the operation is a delicate and pretty little piece of work. The reed that would suit one player would, perhaps, prove utterly useless to another, and *vice versâ*. I find that rather broad reeds of a dark or mottled colour, and carefully voiced, will produce a tone approaching the flute for sweetness in the upper registers, and equally charming (to my ear) in the lower. But as we are told that there is one glory of the sun and another glory of the moon, so there is one glory of the clarionet and another glory of the oboe. Both these instruments, in the hands of a thorough master, are capable of charming the ear of a listener by their beautiful qualities of tone; but much the same can be said of most other musical instruments in the hands of talented soloists. Whether "Woster" selects clarionet or oboe, he must be prepared to endure the torture of hideous noises for the first two or three months, and must put up with the animadversions of his near neighbours. Don't attempt to learn from a book alone, but get a competent master at the very first, and so avoid risk of acquiring bad habits difficult to eradicate subsequently. The oboe, like violin and flute, stands in C, i.e., you can play from any piano or voice music written in treble clef without transposition. I suppose the same could be done with the C clarionet; but I have understood from various sources that the C clarionet is an unsatisfactory instrument. I never could get at the philosophical bottom of this, although I have tried over and over again, so must be content to leave it among other things that "no fellah can understand." Finally, "Woster" must not be too much influenced by what he hears of the playing of either of these instruments in bands, unless they are very fine military or orchestral bands. As to the oboe, it is essentially an indoor instrument, and always, in my opinion, sounds very poor and thin in the open. The oboe can be flattened or sharpened within very narrow limits, but is supposed to be pretty well *fixed*, as all orchestral bands tune (in the absence of an organ) from the first oboe's A, 2nd space treble clef.—O.

[51437.]—**Preventing Springs from Rusting.**—Would "Glatton" (see page 608) kindly inform us how he would prevail upon the springs to "keep their temper" whilst undergoing such a process of "blazing off" several times? Why won't paint or varnish keep off the oxidation, or why can't they be "oxidated" with pure tallow?—A., Liverpool.

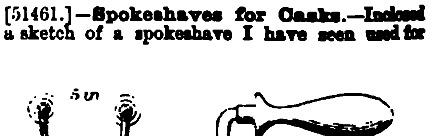
[51438.]—**Mathematical.**—Tan^{-1} $\frac{a+bx}{a-bx}$ is either a misprint (I see you have it tan^{-1} $\frac{a+bx}{a-bx}$ in one place) or a slip of the pen on my part. If the latter, I owe an apology to your correspondent. It should be tan^{-1} $\frac{a+bx}{b-ax}$.—G. W. Bulman.

[51439.]—**Laundry Stove.**—If "Economist" lives where gas can be obtained, he should abolish his stove, and use gas-heated irons. Apropos of the question of examining patents it is worth mentioning that the *Scientific American* of August 18 last contains an illustration of a gas-heated iron, which is called an "invention," patented by Mr. Pedder, of Galveston. It is one of the crudest forms, the mixture of gas and air entering at the top of the iron, and no provision being made for reversing the latter. Much superior forms have been used, to my knowledge, for more than six years in many houses in the City, and one was shown in action at the Gas Exhibition at the Palace. So common are they that in advertisements for ironers it is usual to see the words "gas-irons." I believe that patents were taken out for these irons in the United States; but in spite of that fact the system of "examining" allows of a crude device being patented when better ones are already well known.—Nun. Dor.

[51451.]—**Star Mapping.**—In answer to this, a map on the conical projection supposes a cone placed on a celestial globe, so as to touch the central declination parallel, the apex being over the pole. Then the other parallels and meridians are projected upon cone, as if seen from centre of globe, and the stars filled in in the same manner. I think "R. K. P." will see, then, that everything is supposed to radiate from the apex of the cone, the meridians being straight lines. Having once put in the pin, it remains fixed for each map. Of course, a small amount of distortion is inevitable; but so it is in any attempt to delineate a sphere, or a portion of one, upon a flat surface. I am sorry to say my knowledge of star catalogues is not sufficient to enable me to recommend one containing all stars to the 5th mag. What about the B. A. C.? I should think Mr. Franks could answer this question as well as anyone. There is a catalogue of 1,500 in Proctor's handbook, and a good deal of other information on star mapping. My plan has been to copy the stars from Proctor's large maps first, and then add from "Celestial Objects." The drawback is that there are thousands of stars visible to the naked eye not included in the maps, and it is often troublesome to tell with an altazimuth which is the particular one required. If, however, the distance of the components exceeds 1·5", a Kelner e.p. of 80 or so takes in a large field, and indicates a peculiarity about the star, if it does not divide it. A series of diagrams of stars showing the field of difficult objects would be very valuable to the amateur.—Edwin Holmes.

[51459.]—**Collapse of Tubes.**—Correction.—The 20th line in my answer to above query should read: "Bolton steel hoop seams 3' 0" (3ft.) apart, &c.," not 3in., as shown in answer.—Boswell.

[51461.]—**Spokeshaves for Casks.**—Inclosed is a sketch of a spokeshave I have seen used for



inside of casks, something like a drawing-knife, only a circular blade. The knife is ground on the inside. A is the cutting edge.—T. W.

[51481.]—**Spurious Coin.**—Draw the edge of genuine coin across the face of a doubtful one; if spurious, it will be deeply cut. On the other hand, a spurious coin will make no impression on a genuine one. Or, moisten the coin, and apply a little lunar caustic; the spurious coin will be blackened at the point of contact. (Nitrate of silver is also a test for gold; but if an article is plated, a little scraping may be necessary to detect the fraud.) Some bad coins are really good imitations. I know a pawnbroker who has b
in five times in the course of fourteen
at night. I think "Os." was wro

s coins are mostly made of zinc. I have ore me now in which I can find lead, tin, imony ; but not a trace of zinc. Thanks to ss for his Al plate reactions, I can detect in one minute.—Ex-Blacksmith, Gorton

4.]—**Reed Organ.**—The questions put nder this heading would require a consider- iount of space to reply to definitely. How- will now reply to that which I think ry, and leave the rest to the judgment of the . It is quite possible to obtain a sufficient of tone from reeds to build a three manual lal reed organ, but a considerable amount of e and skill will be required in voicing the n order to produce a sufficient variety of eristic tone in the various stops. I may add e firm of Messrs. Mason and Hamlin have rought out a three manual pedal reed organ ; ave not as yet had the pleasure of hearing or this particular class of organ. G. Minor his organ to contain 20 rows of reeds. Does n rows of 2½, 3, or complete sets of 5 octaves As regards the metal for the reeds, I, for n part, should prefer those made of brass for easons. Taking all things into consideration, nion is that brass reeds are the best, provid- course, the metal is really good. I should y advise the querist to build his organ on tion principle, and buy his tubeboards fitted he reeds unvoiced, he will then be able to e reeds voiced to his own liking, and if he ever attempted the art, I should urgently him to get somebody that knows how to do him. Under such circumstances, this will great amount of trouble, time, and incon- e. Various specifications could be suggested arrangements of the reeds and stops for the ls. For my own part, I should set aside one l for solo performances, having the reeds to produce certain characteristic qualities , such as the clarionet, trumpet, kalophon, , flute, &c. Either of the manuals could be r this purpose, but I should prefer the lower l. For the pedals, I should have two rows . reeds, one voiced soft and the other set and also one 8ft. set voiced rather soft to the ordinary diapason. These sets may con- 30 notes each, which I think will be suffi- Before advising further I should like to how many sets of reeds are required to each tive manual, and of what compass, whether 3, or 5 octaves. The query is not sufficiently e on these points. Will any couplers be ed ?—G. Fryer.

92.]—**Burning and Painful Feet.**—Put eet for half an hour in bran and hot water going to bed, and at any time during the hen painful. Use plenty of bran, and make ot as you can bear, and persevere with it. ou will, I think, find an effective remedy ; , write again, and another one shall be given he Kent Hermit.

93.]—**Laundry Stove.**—Have a damper in e to regulate the combustion of the coal. If ere to use coke, I should think it would heat rons quite as well. No arrangement of gas atus in connection with the present stove be so economical as burning coke and ting combustion by a damper in the flue.— stel.

97.]—**Small Brace.**—What this querist was illustrated on p. 547, Vol. XXXV.— Dor.

97.]—**Small Brace.**—E. Owen will find ll Archimedean screw brace quite suitable. from 2s. at any toolmaker's or ironmonger's. H. F.

97.]—**Small Brace.**—I have drilled a er of small holes in metal with a small medean drill. It consists of a wooden handle hich fits one end of an iron rod about 9in. nd has a coarse worm or thread cut in ; at the end of rod is the socket for drill to fit in. A fitted to the rod, shaped like a spool, and by ; this up and down the rod and drill rotate y. I bought brace and three drills for 6d., cheaper than you can make one, and I think l answer your purpose very well.—W. E. G.

98.]—**Seaweed.**—If E. Owen will advertise ldress, I think I may be able to tell him a cal use for seaweed.—Onward.

98.]—**Seaweed.**—Could E. Owen send us, bout 1cwt. of seaweed for trial ? We think n put it to practical use. We will pay ge and cost if not very far.—William Atlas Works, Bacup.

98.]—**Seaweed.**—The reply to this query ds on the kind of weed plentiful, locality, The weed called "carrageen moss," is used ke a kind of tea for consumptive patients. n other kinds are dried and utilised for the g of cheap furniture. Seaweed used to be yed in glass manufacture, but has, I believe, been supplanted in a great measure ; and, lastly, seaweed makes very fair manure for many things. —B. H.

[51500.]—**Mathematics.**—(1) Area of base = 10 × 11 = 110 sq. ft. ; area of top = 5 × 5 = 25 sq. ft. ; average area = 110 + 25 ÷ 2 = 67½ sq. ft. ∴ cubic contents = 67½ × 5 (height) = 337½ c. ft. ; (2) Area of base = 20 × 10 = 200 sq. ft. ; area of top = 15 × 5 = 75 sq. ft. ; average area = 200 + 75 ÷ 2 = 137½ sq. feet ; ∴ cubic contents = 137½ × 5 (height) = 687½ c. ft.—Salvo Jure.

[51500.]—**Mathematics.**—

ft.
10ft. × 11ft. = 110 square of base.
5ft. × 5ft. = 25 square of top.

2) 135

67·5 mean square.
67·5ft × 5ft. height.
5

337·5 cubic feet in (1) heap.
In (2) heap 687·5 cubic feet.—G. H. F.

[51500.]—**Mathematics.**—In reply to "Poor Labourer," I beg to submit the following figures as the correct method of solving his problems:—

ft. in.
(1) 10ft. 0in. × 11ft. 0in. = 110 0 area of base.
5ft. 0in. × 5ft. 0in. = 25 0 area of top.

135 0 ÷ 2ft.
= 67ft. 6in. × 5ft. 0in. = 337ft. 6in. cube.
ft. in.
(2) 20ft. 0in. × 10ft. 0in. = 200 0 area of base.
15ft. 0in. × 5ft. 0in. = 75 0 area of top.

275 0 ÷ 2ft.
= 137ft. 6in. × 5ft. 0in. = 687ft. 6in. cube.—Evans, Dublin.

[51500.]—**Mathematics.**—

ft. ft.
$$10 \times 11 = 110$$
$$5 \times 5 = 25$$
$${}^{2}\sqrt{110 \times 25} = 52{\cdot}44$$
$$187{\cdot}44$$

$(187{\cdot}44 \div 3) \times 5 = 312\frac{2}{5}$ cubic feet. Ans. No. 1.

ft. ft.
$$20 \times 10 = 200$$
$$15 \times 5 = 75$$
$${}^{2}\sqrt{200 \times 75} = 122{\cdot}47$$
$$397{\cdot}47$$

$307{\cdot}47 \times 5 \div 3 = 662\frac{9}{20}$ cubic feet. Ans. No. 2. —A. McCormack.

[51505.]—**Land Tax.**—The poor rate is the usual basis. You can appeal to the Commissioners at the proper time. You will then have to prove that the property in the parish is unequally assessed, and that yours in particular is over-assessed—that you are assessed on the gross rental instead of rateable value. It is desirable to redeem if the property is likely to become more valuable. The rule is: "the money paid be sufficient to yield interest less by 17½ per cent. than was required by Act 42, G. III., c. 116." The sum to be paid depends upon the price of Three per Cents in the week after the contract. For fullest details see "Land Tax and its Redemption," by W. Evans, a copy of which appeared in the *Estates Gazette* (Fetter-lane) about two months since ; I do not remember the date. Roughly, the sum to be paid is 20 to 30 years' purchase.—R. Hannen.

[51506.]—**Earth Contact.**—Your cheapest way to form an earth circuit will be to solder your return wire to a gas or water pipe ; if you have not got either, get a thin copper plate 16in. square, solder your wire to that and bring it a few feet under the surface in damp soil. That will be cheaper than using a return wire.—Fitter.

[51507.]—**Model Compound Marine Engine.** —I doubt if a model of the size you name would work well without a good deal of attention to the boiler steam pressure. I don't think you will get the necessary steam pressure, say, 80lb. on the square inch, unless you use a very good boiler, which would come expensive, and may possibly prime ; and, as a consequence, upset the proper expansion in the cylinder. 2 to 1 is the proportion generally used in large engines ; but as you, in all probability, will not have enough pressure in the small cylinder for the necessary expansion in the large ditto, I should recommend your making the proportions 1½ to 1. You will find it more satisfactory to have two cylinders 1¾in. by 1¼in. to your engine, and work both direct from the boiler. I presume you are not thinking of economising the fuel in the model in question.—S. Austel.

[51509.]—**Rabbits.**—Your rabbits are just the age for breeding. A very useful book entitled, "Pigeons and Rabbits," by E. S. Delamer, price 1s., is published by G. Routledge and Sons, London. —J. E. Norman.

[51509.]—**Rabbits.**—"Pigeons and Rabbits," by E. S. Delamer (1s., published by Routledge), is a good book. The author says that rabbits breed before they are six months old ; but this is the earliest age at which they should be allowed to do so.—R. A. R. Bennett.

[51516.]—**Commercial Units and Metallic Ores.**—"Pyrites cupreous 6d. per unit c. i. f., G.B." For an example take Rio Tinto pyrites. These contain on an average about 47 per cent. of sulphur. Every per cent. in a ton is called, in commercial phrase, a "unit": therefore the price of the sulphur in a cargo of Rio Tinto pyrites which was found by analysis to contain, say, 47 per cent. of sulphur, at 6d. per unit, would be 47 times 6d., or 23s. 6d. for every ton of pyrites. The copper in cupreous pyrites is sold quite distinct from the sulphur, and the price is calculated on an altogether different basis; "c. i. f. G.B." means that the merchandise is delivered by the vendors, all cost, insurance, and freight paid to any port in Great Britain. "c. i. f." is sometimes written "c. f. and i.," and instead of "G.B." it is often put "U.K.," or United Kingdom.—Rio Tinto.

[51517.]—**Compressed Gas.**—Cubical space occupied by gas varies inversely as the pressure, so by a rule-of-three sum you get cubical contents. Taking initial pressure of gas same as atmosphere— 1728in. : 15lb : : 1,000lb. :—Ans. — 8·6 cubical inches. I should think you will require some kind of a reducing valve on your reservoir to make gas burn.—W. E. G.

[51519.] — **Chemical Action of Etching Copper.**—When chlorate of potassium and hydrochloric acid are mixed together, a body is produced, which Davy termed euchlorine, but which is probably a mixture of chlorine tetroxide and free chlorine. These acting upon the copper form a chloride, which then combines with the chloride of the alkali, produced by the action of the HCl on the $KClO_3$, giving rise to a double salt. With nitrous acid, which is the term applied to the impure nitric acid of commerce, nitrate of copper is formed.—W. E. Haden.

[51520.]—**Granule Carbon Battery.**—I think you will find, by using ammonium chloride, acidified with hydrochloric acid, instead of the Zn chloride, which forms a hard yellow incrustation on the Zn, that your mistake will be rectified. I myself have worked it for thirty hours at intervals, and at one time.—Hugh.

[51520.]—**Granule Carbon Battery.**—I have three cells, "granule," about same size as "Hill's," and find them work well charged as follows:— Outer cells: ¼lb. bichromate potash dissolved in about half a gallon of warm water. Cool, and add about one-third of a gallon of muriatic acid. Inner cells: place in each porous pot 2oz. chloride ammonium mixed to paste with ½oz. muriatic acid, and fill up with water.—G. H. F.

[51521.]—**Opening Railway Bridges.**—There is a swing railway bridge on the Manchester and Stockport railway over the canal at Sankey, and it is proposed to use these bridges over the Manchester ship canal, near Warrington.—W. E. G.

[51524.]—**Trembling, &c.**—This case can only be prescribed for after personal examination ; so consult a doctor. If you have not received benefit from medical advice, the reason is probably that you either did not strictly follow that advice, or that you did not sufficiently describe the particulars of the case, and your habits and mode of life. I am sorry I cannot assist you ; but you would, no doubt, derive much benefit by adopting the anti-indigestion diet given in a recent number of this journal. —The Kent Hermit.

[51525.]—**Magnetism—Science Examination.**—Have you got Buckmaster's "Electricity and Magnetism"? If you have not, you ought to get it, as it is written expressly for the science and art students. I don't know any book entirely composed of answers to questions given during past years. There are plenty of advanced questions in Buckmaster ; or you can get all the questions set in former years from the secretary of the Science and Art Department, South Kensington, S. W.— R. A. R. Bennett.

[51525.]—**Cram-Book in Subject IX.**—I have taken the liberty of altering the title of this very unsatisfactory query, and beg to inform "R. R. R." that I believe there is such a book as he desires, but I decline to advertise it. If he wants to pass an examination he should study the subject properly. The existence of such books as the one inquired for has done more harm to science teaching than can easily be estimated.—Wm. John Grey, Elswick Science School.

[51526.]—**Cement.**—"Coaguline" answered very well.—R. A. R. Bennett.

[51527.]—**Sulphate of Copper.**—When I answered this question before, I was under the impression that brass would dissolve quite easily in sulphuric acid. On actually trying it, however, I find that it is a good deal of trouble to get it to

[illegible] If [illegible] thermometer [illegible] water. [illegible] will get splashed [illegible] whether [illegible] sulphuric [illegible] Couldn't [illegible] in a very [illegible] if heated [illegible] quicker.—R. A. R. [illegible]

[51634.]—**Stern Wheel Steamer.**—[illegible] could get some of [illegible] favour [illegible] cylinders with [illegible] horizontal, and drive the wheel [illegible] best size and position of the wheel [illegible] motion is already [illegible] therefore it should be nearly as wide as the boat, as to putting it out of sight [illegible] over it, but [illegible] very large wheels placed on a frame extending from the stern.—T. P.

[51635.]—**Moisture in Air.**—[illegible] ploy a wet and dry bulb thermometer [illegible] g the moisture from [illegible] the formula given in Ganot's "Physics."—[illegible] ART.

[51635.]—**Moisture in Air.**—This can readily ascertained by means of Daniell's hygrometer, and these are supplied with instructions for use. It is edless to give them.—W. E. HADEN.

[51542.]—**Boro-Glyceride.**—Full particulars of arff's preservative will be found in VOL. XXXIV., 367.—NUN. DOR.

[51542.]—**Boro-Glyceride.**—This is prepared heating boracic acid with 1½ times its weight of ycerine; when entirely dissolved, and allowed to ol, it forms a tenacious deliquescent mass, soluble water and spirit. In solution it is used as an tiseptic for preserving meat, &c., and also for rgical dressings.—W. E. HADEN.

[51550.]—**Colouring Baskets.**—Wouldn't dson's dyes answer your purpose?—R. A. R. ENNETT.

[51551.]—**Chimonanthus Fragrans** is of order olygynia, in class Icosandria. It is sometimes lled the Japanese Allspice. It is multiplied by yering. The leaves fall about November, the llow flowers appear at Christmas time, and have very fragrant odour. It was brought over to this untry by Admiral Harvey about eighty years go; it grows out in the open—a light soil with uthern aspect suits it best. The leaves may be cked in the summer or autumn: it will not imde the growth. Dry in the sun, roll up, and d pack tightly down in a box in a dry place, so to obtain the ripeing; use as tea.—A LOVER OF EAN FOOD.

[51554.]—**Preserving Butter, Fish, and oultry.**—After repeated trials, I find the best ticle for the above purpose to be "Conservealait."—J. E. NORMAN, Worle, Somerset.

[51556.]—**Utilising Oxide of Tin.**—Oxide of n is used for polishing plate, under the name of tty powder. By fusing it with excess of caustic da, stannate of sodium would be formed, which used as a mordant by dyers; or it may be reduced the metallic state by fusing with charcoal and dium carbonate.—W. E. HADEN.

An Installation of Electric Power and Light.—At Archway House, Bush-lane, Cannon-street, E.C., Mr. C. R. Heap, the agent for the [illegible] Company, of Philadelphia, has [illegible] a small installation of electric power and lighting by means of Kabath's storage batteries charged by the current from the mains of the Metropolitan Brush Company. On any day of the week from, say, 10 to 4, Mr. Heap will be pleased to show what can be done by means of electricity in lighting the apartments of a house or in working [illegible] machines, or the appliances of an amateur [illegible] workshop. The excellent little Griscom motor which attracted so much attention at the [illegible] can here be seen driving sewing machines, [illegible] drilling machines, ventilating fans, and last but not least, a dentist's drilling apparatus [illegible] arranged that the motor and [illegible] desired position, the drill [illegible] a flexible shaft. We have [illegible] Kabath's secondary cell [illegible] XXXV [illegible] as modified and improved [illegible] Archway House, just as it [illegible] a dwelling-house. [illegible] is well worth a visit by [illegible] the utilisation of electricity for [illegible] power.

UNANSWERED QUERIES

[illegible]

[illegible]

[illegible]

QUERIES

[illegible]—**Chemical.**—Will some kind friend [illegible]

[illegible]—**Nickel Plating.**—I shall be glad of any hints on above. In making a solution and batteries I have been guided by instructions given in Watt's "Electro-Metallurgy." I made a solution of sulphate of nickel neutralised with ammonia, and added a solution of sulphate of ammonia neutralised with H_2SO_4, in each case pure. I made merely a small quantity for experiment, say about a pint, but I should say the proportion of metal would be [illegible]. From this solution I have obtained no result whatever. No deposit—good, bad, or indifferent—is made. I have also tried a solution spoken of in Watt's work consisting of sulphate of nickel, tartaric acid, and potassic hydrate, but with a like result. I have two batteries each consisting of a jar about 1gal., containing a cylinder of copper, and a porous cell containing a zinc bar. Dilute sulphuric acid [illegible] in former, and concentrated solution of common salt acidulated with HCl in the latter. The connections are all right. The amount of anode exposed exceeds the surface to be deposited upon, which I have taken care to have thoroughly cleaned. I have first tried one cell, then two, arranged both for quantity and intensity. There is evidently some necessary condition omitted, and I shall be obliged if any correspondent would suggest it or recommend a well tried solution. I wish to make a bath of about 1gal., as I have a tank of that capacity. Will the cells I have named be sufficient to work it? My zincs expose a surface of about 10 or 11 sq. in. each. I have read the articles in Nos. [illegible] and 811, but they do not furnish the information I want. I have been successful in depositing silver and copper; but nickel is quite new to me; so perhaps some experienced reader will kindly help me out of a—DIFFICULTY.

[51558.]—**To Mr. Wetherfield.**—(1) A.'s horse came into my field of growing corn and did damage to the extent of £4, according to the valuation of a licensed valuer. A. says his horse came through my hedge (i.e., at a place where the ditch was on A.'s side), and says on that account he is not liable. Is this so? Is he not bound to see that his stock shall not injure his neighbour's crops? I deny his statement as to place of entry, and have claimed the amount of damage in writing; but also wish to know if, in taking the case to the County Court, I should also state the valuer's charge as part of the debt? Or must that be left to the judge to include it in "costs"? (2) Can you recommend a work on the law as relating to the duties, responsibilities, privileges, &c., of land occupiers, tenants, owners, &c., as to hedges and fences?—H. L. R. H.

[51559.]—**Tonnage of Steamers.**—Will some one kindly explain the difference between awning-decked and spar-decked steamers?—LONDON RIVER.

[51560.]—**The Atomic Theory.**—According to the atomic theory the elementary units of mass are in all respects equal, are absolutely hard and inelastic, absolutely inert, and therefore purely passive. But, according to the atomic theory of chemists, some atoms are much heavier than others; and in fact the chemical theory will not work with the mechanical. How is this? Which is the correct atomic theory?—NEMO.

[51561.]—**To Mr. Wetherfield.**—I advertised some shares in Starr-Bowkett Society, £30 paid in, for £23. A gentleman wrote and told me to call with the books. After seeing them he agreed to buy them, less 12s. (there only being £29 8s. paid), and paid 10s. deposit, and I left the books with him. He now refuses to buy them on the ground that he will have to pay £2 working expenses on withdrawal, although the rules were in the book to that effect when he saw them. Having lost the opportunity of selling them now, can I compel him to complete the purchase, and what steps ought I to take?—H. KNOWLES.

[51562.]—**Burnishing and Setting Razors.**—Will some reader inform me how razors are burnished and how to set same to the finest edge? If possible, I should like to know the method used in their manufacture.—[illegible]

[51563.]—**Shaft.**—Will some one please tell me if my shaft is strong enough to carry 12 arms, each having [illegible] at ends and 16ft. long from centre of shaft, fitted [illegible] from top. Shaft is a 14ft. length of steam tube, 2in. inside, 2½in. outside, to stand in a vertical position with bearings at about 2ft. 3in. from ends, and [illegible] 12 revolutions per min. If not, what will do?—THOMAS.

[51564.]—**Microscopic.**—In a microscope by one of the best makers the 100th part of an inch in the stage micrometer with a $\frac{4}{10}$ object-glass corresponds to 7½ [illegible] of an inch in the eyepiece micrometer in B eyepiece. 7½ [illegible] is equal to $\frac{15}{80} = \frac{3}{16}$; and $\frac{3}{16}$ of an in. is the same thing as 18¾ hundredths. That is to say, a $\frac{4}{10}$ [illegible] glass in a first-class microscope only magnifies with the second eyepiece 18¾ diameters. How am I [illegible], and how can I accurately tell the number of diameters any given object-glass and eyepiece magnify, including eyepieces not used for the micrometer?—L. B. B.

[51565.]—**Photographic Printing.**—To MR. [illegible]—Will you kindly tell me where I am working amiss? My prints are a beautiful plum colour before going into the hypo. bath, to the point, but they lose it all after having been in the latter bath.—I want to keep a stock solution of saturated hypo. How many ounces of this ought to be added to the pint of water for fixing prints?—As alum is said to assist in eliminating hypo. from negatives; would it do for prints, water being a [illegible] consideration?—R. D. H. B.

[51566.]—**Odourless Waterproofing.**—Can any reader kindly give me a recipe for making either cloth, [illegible] or [illegible] waterproof? The preparation needed is one that will withstand immersion in beer when barrelled without imparting taste or smell to the beer. Would a mixture of gelatine answer the purpose, and if so, how long would such a coating stand waterproof when immersed in the barrel filled with beer? Any recipe likely to be of service will be much valued.—H. F. [illegible]

[51567.]—**Tenant's Liability.**—To "LEX."—To what extent is B. liable for dilapidations under following circumstances?—A takes a house on three years' lease. After the three years he keeps on as yearly tenant for nearly two years, and then quits in favour of B. by landlord's sanction. B. holds the house for several years without any fresh lease. On leaving the house, is he liable for damage done by A. while a tenant, and is he bound to repair according to terms of A.'s three years' lease?—X. Y. Z.

[51568.]—**The Audiphone.**—My hearing is considerably impaired through the thickening of the eustachian tube, or throat deafness. Can anyone tell me if the audiphone is practically of use in this case for conversation, hearing lectures, &c. An ear-trumpet maker told me it was not; but he might not be unbiased. Before trying one of these rather costly appliances, I should feel greatly obliged for any information about them, which might also be a boon to others besides myself.—A. E. C.

[51569.]—**Legal.**—If a son of a widow goes wrong, and leaves his wife and children chargeable to the parish, is the widow compelled to maintain them? There is property coming to the son at the widow's death.—S. CRANE.

[51570.]—**Blacking Machinery.**—Will any reader inform me what sort of machinery is required for blacking making? Also, if there is any machine for making small quantities, and where obtainable?—T. E. TAYLOR.

[51571.]—**Steam Punt.**—I am anxious to build a steam punt for use on a small narrow river where weeds are very numerous. For this reason I have decided on a single wheel astern as in the American up-river boats. Any hints as to the best way to build the boat—size, pattern, and power of engines, boiler, &c., with sketches, will be esteemed a great favour by—E. P.

[51572.]—**Oxide of Copper Battery.**—To "SIGMA."—Please say if this cell is suitable for working incandescent lamps. If so, what size of cells would you recommend, and will the common black commercial oxide answer, which is sold at about 2s. per lb.?—C. TURNER.

[51573.]—**Filling up Crests, &c., on Plated Articles.**—I have just bought a quantity of plated articles, all having crest and initials engraved. Is there any method of filling up?—DEALER.

[51574.]—**The "English Mechanic" and Time.**—The first volume of the ENGLISH MECHANIC ended on Sept. 22, 1865. The XXXVIIth was completed on the last day of August, 1883. When will the volume be completed in June?—NUN. DOR.

[51575.]—**The Passion Flower.**—Can any of your readers tell me if it is possible to bloom this plant in a pot, and if so, how old must it be? Is it advisable to stop it severely?—S. R.

[51576.]—**G.E.R. Engines.**—Can any reader give some account of the six-coupled goods with a small wheel in front (presumably a bogie) of this line? I have seen one or two at March and on the Cambridge main line.—BUFF.

[51577.]—**Rushton's Self-Acting Fountain.**—Will some reader tell how I can make one of the above fountains? It is started by blowing for about a minute. A sketch will greatly oblige.—CHEMICUS.

[51578.]—**Rhinoceros Horn.**—Having broken about 6in. off the end of a walking stick made of this material, I shall be obliged by practical information how to proceed to draw it out to its original length, and how to repolish?—C. F. A.

[51579.]—**Drilling Emery-Wheel.**—[illegible] reader inform me how I can drill [illegible] emery wheel 1¼in. thick?—S. J. R.

|—**Model Boat.**—I have a model boat 5ft. should like to make an electric engine to drive I would be able to make myself, but do not ctly what pattern to make it. Would any of me out of my difficulty? The engine to work -WAUN.

|—**Windmill.** — Living in a very exposed .should like to know it I constructed a wind- ld it do to drive a dynamo-electric engine for ght purposes? If so, what pattern would it made?—WAUN.

]—**Violoncello Strings.**—What is the cor- h of strings of a violoncello from the nut to the E. H.

—**Cement for Aquarium.**—Can any of ne what will stop an aquarium from leaking? alt water, so there must be nothing in the hich would be acted on by the water. Every- mmends a cement made of white-lead and red- d together into a paste. I don't believe in it. re good reasons for not doing so, since the has been mended four times in succession with g fresh stuff each time, and it runs out now as t did as first. Each time the water has run out g one night in the aquarium. I am afraid if n recommend another cement, I shall have to e glue, and I don't want to do that because of ionable smell, as I said once before in last vol. say that the aquarium is 1ft. high, and holds of water, so that the pressure is very consider- any one can tell me of a cement warranted to pressure, and not composed of white and red all be very grateful. It is no use referring to bers, for I haven't got any, except this year's. swer as soon as possible, as it is very awkward ow where to put the anemones, &c., which were arium.—R. A. R. BENNETT.

|—**H.P. of Engine.**—Will some kind reader he h.p. of a six-wheeled coupled locomotive aving 5ft. 1in. wheels, 18in. cylinders, 26in. essure of steam in boiler 140lb. to the sq. in.? se of baffle plate in firebox?—EXON.

|—**Water-Motor for Blowpipe Fan.**—I greatly obliged if any reader could inform me nstruct a water motor (model) to work small blowpipe.—W. MORGAN.

|—**Windmill for Pumping Water.**— e one kindly oblige with a few hints as to the ion of a simple windmill suitable for raising the supply of a large house, and the best way of the power to the pumps?—KERAULOPHON.

|—**Preparing Millboard, &c., for Oil g.**—Can any one tell me how to prepare mill- rtridge paper, or canvas for oil painting—the the preparations, or any books on the subject? ATEUR.

—**Nervousness.**—Can any of your scientific rs offer a remedy to one suffering as follows?— months ago I rode a long bicycle race, which l and excited me considerably. Next day I felt upid, with retching and a touch of dysentery. 28 days I got quite melancholy—hating all en music): would rather not look at the light sun; a continual noise like frying of meat in ; a shortness of breath, an excited feeling, rest- &c. After some time I found a little more ut I am still suffering from a bad memory and nergy. I was a strong thinker in time past, and l of excelling in every engagement—whether r mental. I feel my condition like a millstone around my neck. I feel as if there is some in- the usual pulse in my temples, and my skin is ot, especially my head. I have consulted some s, who told me it would wear away. I am not a or smoker; age 26—married some months. the best course to take? My appetite has been l all the time.—A. McC.

]—**Water Colours.**—Would some one inform method of keeping water-colours moist after them myself, and how to mix them in the to make them adhere and work nicely? I am of the ordinary dry colour that you buy at so r lb.—H. M. F.

]—**Electrical.** —To MR. LANCASTER OR —(1) Having a tangent galvanometer, I should now how to calculate current in ampères by it. It has (*a*) two turns of thick wire, and (*b*) s (ten turns each, making twenty) of fine wire. m. of wire 6·75in. Please give earth's intensity ear as used in this answer. (2) Does any type telegraph use a single wire for transmission of (3) If mercury be added to melted zinc for attery rods, is not the heat sufficient to vaporise therwise, is this method as satisfactory as surface amalgamation?—CARBON, London.

]—**Cigarette Machine.**—Will any corre- kindly tell me how to make a little machine for igarettes, as I find it rather difficult to make them ?—G. FRYER.

]—**Utilising Vegetable Fibre.**—Will any ndly describe machines for extracting the fibre Agave, Bromelia, and other leaves?—NICARA-

]—**Portuguese Grammar and Diction-** an any one recommend a really good Portuguese , and also an exhaustive dictionary?—LINGUA.

]—**Crystoleum Printing.**—Would "R.B." her reader give a few hints concerning the mix- ints, so as to produce the different colours re- crystoleum painting? Also is the preservative ng crystoleum permanent, and medium, one and thing, as a tube of medium cannot be bought— les of preservative medium?—M. WILSON.

]—**Chinese White.**—Of what is this substance , and how is it prepared? What solvent should o keep it moist or to moisten it when dry? I most impossible to get rid of grittiness with SALVO JUKE.

]—**Platinum.**—Will some kind subscriber (a tell me the names of the substances, acid and alkaline, that act on platinum? That is, what substances corrode it? Will caustic potash solution or chlorine act injuriously on it? Kindly state all known substances that act injuriously on it?—HOROLOGICAL.

[51597.]—**Oxide of Copper.**—Could some kind subscriber tell me of a cheap method of making oxide of copper? I am aware that by heating sheet copper red hot and plunging into cold water a film of oxide forms on it, but is there not a cheap method of making it from the sulphate or any other simple way?—HOROLOGICAL.

[51598.]—**Platinum in Battery.**—Would our kind contributor "Sigma," tell me with what solutions I may safely use platinum as a negative in a battery, &c.? Can it be used in sulphate mercury battery, caustic potash battery solutions, caustic soda solutions, and any of the chlorides and chlorine? Would it be safe to leave platinum in mercury for any length of time?—H. W. H.

[51599.]—**Haulage.**—(1) What would mineral cost per ton per mile drawing on ordinary tram rails by men or boys, when men's wages are 4s. per day? (2) What would it cost by horse when horses' keep and drivers' wages amount to 6s. per day? (3) What would it cost on edge rails? A rule for the above will oblige.—SCOTTIE.

[51600.]—**Chemical.**—For purposes of photography I keep ready dissolved 10gr. each of citric acid and potassium bromide in 20oz. of water. In the course of a week after it is made up, there appears in it a pure white fungus-like mass. What is this? Will these salts not keep in solution?—VOLVOX.

[51601.]—**Photographic.**—Can any reader name a book on the theory of photography? That is, explaining what are supposed to be the chemical reactions in dry-plate films. I have Abney's "Instruction in Photography,' but would like another.—VOLVOX.

[51602.]—**Testing a Piano.**—I should feel obliged for information concerning the different parts to notice when buying a piano.—G. O.

[51603.]—**Corliss Valve Gear.**—Will "Glatton" or any other gentleman be kind enough to embalm in ours a graphic method of observing the action of the above gear? All books on valve gear with which I am acquainted give this gear, considering the extent to which it is used, a very cursory and unsatisfactory notice. Could the well-known Zeuner diagram, as used for ordinary slide valves, be modified so as to render it applicable to the Corliss?—ECCLESTON.

[51604.]—**To "Sigma."**—In a back number you allude to the superiority of a certain French steel for magnets. Could you inform me where the works are that produce it? I know a firm that would try and make some in England, if a sample could be had of this peculiar French steel.—MAGNETO.

[51605.]—**Water Power.**—I am putting down a breast waterwheel, 7ft. diam. The water strikes the wheel one foot nine inches from the top. How much water per minute must pass through to gain one horse power?—FARMER.

[51606.]—**Repairing Engine.**—I am about to repair a 25-horse horizontal steam-engine which at present will scarcely drive three ordinary circular saws. Now what I want to do is to increase the power as much as possible. I may also add there are two valves, main and expansion, but owing to the small amount of power, the driver has taken the expansion valve off and worked the engine with the main valve cutting steam off at ½ stroke. Now what I thought of doing was to take a slight chipping off the valve face and turn the eccentric round so as to cut steam off at ¾ stroke. Of course, in this case more steam will be required. Will anyone kindly tell me of any other way without increasing pressure in boiler, which is at present 60lb.? Main steam valve faces and throttle valve in good order, and engine quite free from all binding. I may also state the driver says the engine has never given anything like its proper power ever since it was fixed. Any answers would greatly oblige.—YOUNG FITTER.

[51607.]—**Dissolving Human Hair.**—I have read in a back number that hair can be dissolved by boiling in a solution of caustic soda. If this is correct, could any one tell me how I could withdraw the caustic soda, leaving all the constituent parts of the hair in a state of solution? Or, by what other means could I obtain the same result?—NO CHEMIST.

[51608.]—**Patterns for Boots and Shoes.**—I want to understand the art of cutting patterns for boot and shoe uppers. Is there a book published on the subject? The information given by "Jack of All Trades" some time ago is too meagre for my purpose. I cut my patterns on a last, but do not know how the height at back and side and length of vamp is regulated. Will any one tell me? To amateurs, as fathers of families with small means, as well as myself, this information, I think, would be very valuable.—POLITZER.

[51609.]—**To Mr. Wetherfield.**—There is a clause in the New Bankruptcy Act which provides that a tenant's property to a certain amount is protected from seizure by landlord. Does this apply to matters of rent, or only to cases of bankruptcy or liquidation?—POLITZER.

[51610.]—**G.E.R. Locos.**—Will some one give particulars of a train engine (No. 131) which I understand is being turned out at Stratford? Also are there any more of the new coupled expresses coming out—562 class? What are the cylinders and wheels of Nos. 556, 616?—H. S. P.

[51611.]—**Levelling.**—Could any correspondent give me some advice as to the best kind of level for rough use in foreign countries? Is a "Dumpy" or a "Y" preferable? Also, what is an Abney's level, and a builder's level? Any information will oblige.—E. E. R. T.

[51612.]—**Tunnelling.** — Can any correspondent kindly give me some information as to the method of keeping the levels and lines of a tunnel, which is being driven from both ends, so as to insure the work meeting correctly? I shall be glad of any information on this subject. Can anyone also recommend me a cheap and reliable book on tunnelling? How is the area of the section of a tunnel having curved top and sides calculated?—E. E. R. T.

[51613.]—**Knapp's Solution.**—A description of the mode of preparing the above solution, and the method employed when using it for the titration of grape sugar, will oblige.—N. C. B.

[51614.]—**Sliding Door.**—I have a sliding door to my workshop which it is requisite should be kept shut. Can any of our numerous readers inform me of an appliance that will shut the door when left open—something that will not make it much harder to open? I may add that the door runs on pulleys at the top.—W. LISTER.

[51615.]—**Brass and White Ornaments.**—How are brass or white metal cast figured ornaments finished in Sheffield, Birmingham, or elsewhere?—W. WILSON.

[51616.]—**Hosiery Goods.**—In buying hosiery goods (lambswool shirts, pants, &c.), the seller tells me the quality is 10, 12, or whatever the gauge may be. Kindly explain what is meant by gauge and how to tell the different gauges? I find each article marked with small holes (as if the stitches were left out), thus ⁚; those of a finer quality having more holes. Can you tell the gauge by these holes, and if so, how do you count? Or do different makers use different marks or holes for the same gauge?—D. M. L.

[51617.]—**White Metal.**—Will one of ours kindly inform me how to mix white metal, such as cheap brooches are made of?—J. SMITH.

[51618.]—**To Mr. P. J. Davies.**—Will you be so kind as to show me in plain figures how the following is worked out? We have the town's water in the mill. The mill is 63ft. high; the pipes are ½in. Suppose there is 100lb. pressure at the bottom, what will there be at the top? Also, will you give me instructions how to make a counter as you showed attached to the pump a few weeks back to count 126,000?—YOUNG ENGINEMAN.

[51619.]—**Specific Gravity.**—Will any kind reader inform me how to calculate, from the sp. gr. of any solution, the amount of solid matter which is contained in, say, a gallon of distilled water, and also give me a rule by which I shall be enabled to reduce a liquid from one sp. gr. to another by the addition of distilled water?—SPECIFIC GRAVITY.

[51620.]—**Photographic.**—Will any reader inform me whether the photographic business is a profitable one or not in Tasmania—if dry plates and the necessary chemicals can be obtained at about the same price in Tasmania (Launceston) or Melbourne as they are in England, or would it be advisable to take out a stock of materials?—A WOULD-BE PHOTOGRAPHER.

[51621.]—**Glue.**—Please inform me how to make glue acid and waterproof.—J. GRANT.

NOTICES TO CORRESPONDENTS.

CORRECT Solutions to 848 by Dicky Sam, F. V. P., and H. Jacobs; to 849 by J. Keylbee-Hewson, E. Stanley Follwell, F. V. P., Dicky Sam, C. Planck.

J. H. B.—Game received with thanks.

F. F. B.—Thanks for slip.

H. JACOBS.—Sorry you are not able to continue.

THE *Matlock Register* is about to start a two-move problem tourney. Those anxious to join it can obtain particulars by communicating with the Chess Editor, Mountain View, Clontarf, Dublin.

Holloway's Pills will render to delicate invalids the most essential service when they suffer from bilious affections, loss of appetite, or indigestion, through damp or variable weather. Lowness of spirits, sick headache, dimness of sight, faintness, and vertigo resign their perplexing sway after a few doses of this regulating medicine.—[ADVT.]

no one can object to a patent on the ground that it comprises more than one invention. The exact force of this section can be known only when it has been determined by the Court, but no exception can be taken to it if it means, in the case of a machine, the invention as a whole, and certain parts which might otherwise be the subject of separate patents. Provision is made for the granting of a patent to the legal representative of a deceased inventor, if application is made within six months after his death. Section 40 provides for the issue of an illustrated journal of patented inventions containing reports of patent cases decided by courts of law, and such other information as the Comptroller may think useful or important. Section 45 is very important, and is that referred to at the commencement of this article; for as phrased it appears that applications left at the office between now and Dec. 31 will pay the diminished fees, and escape the examination and the liability to grant licenses. Thus the provisions of the Act relating to applications and proceedings thereon shall have effect only in applications made after the commencement of the Act. Every patent granted before the commencement of the Act, or on an application then pending, shall remain unaffected by the provisions of the Act relating to patents binding the Crown and to compulsory licenses. "In all other respects (including the amount and time of payment of fees) this Act shall extend to all patents granted before the commencement of this Act, or on applications then pending, in substitution for such enactments as would have applied thereto if this Act had not been passed." We quote that subsection literally, for if it really means what it says, there will be a decided advantage in getting applications filed before the end of the year. By Section [illegible] the Comptroller is empowered, on request in writing accompanied by the fee, to correct clerical errors, &c., and by Section [illegible] it is provided that any application, notice, or other document may be sent by post, and shall be deemed to have been left, made, or given, at the time when in the ordinary course the letter would be delivered. It will be sufficient to prove that the letter was properly addressed and put into the post. Another section, [illegible] contains the important proviso that where any discretionary power is given to the Comptroller, he shall not exercise it adversely to the applicant without giving him an opportunity of being heard personally or by his agent. Extensive powers are given to the Board of Trade to make such general rules and regulations as may be considered expedient, and on these will depend much of the success of the Act in settling the vexed question of Patent Law reform.

EASY LESSONS IN BLOWPIPE ANALYSIS AND PYROLOGICAL MINERALOGY.—XII. (AND LAST).

By Lieut.-Col. W. A. Ross, F.G.S. (late R.A.)

Rationale of Outer and Inner Ball Formation. Sodium and Non-Sodium Yellow Flames. Cause of the Colour of Sapphire, Emerald, Amethyst, &c.

C.—"Before proceeding, Professor, would you kindly say if it is *necessary* to [illegible] calcium-borate ball before [illegible] B.B. to the boric acid, in order to [illegible] inner balls?"

"Certainly not. You can apply the [illegible] ball (XXXVII., 590), just [illegible] bead, B.B., and almost [illegible] the inner balls."

C.—"When I return shortly to America I [illegible] to correct and contradict the reports spread there by your [illegible] friends in England and elsewhere [illegible] of your system of analysis, and shall further maintain that I have the best possible evidence (that of my own eyes) for stating that *silica* is not the simple combination of two elements which it is universally supposed to be at present. But how do you explain the formation of these "inner balls" communicated to calcium pyroborate by silica; and, indeed, that of the *outer* balls also: a fact discovered by you apparently in 1869 (*fifteen years ago!*) but not yet taken into consideration by men of science, as I think it might have been?"

"I feel that in you, Professor C., I shall have my first *real* friend,—a man not only capable (for many are that), but having the sincere *wish*, and the influence or power, to defend or elucidate my simple exposition of THE TRUTH in philosophical analysis. The small sphericles or balls formed within a bead, by the application B.B. of lime and about 12 other oxides, to boric acid, are evidently due to the respective *cohesion of two liquids*—liquid, of course, only when in a state of fusion B.B.—which do not dissolve each other (although that is not the opinion of Professors Roscoe and Schorlemmer), but possess nearly the same specific gravity; just as this oil, poured into diluted alcohol, remains suspended within it in the forms of perfectly spherical masses. The two liquids in the case of lime applied B.B. to boric acid, are the latter (containing), and calcium borate (contained). The boric acid coheres to as near a sphere (see Lesson IX., para. 10, page 433, 'E.M.'), as the platinum-wire ring to which it clings will allow, and hence the advisability of making the ring as nearly round as possible. The calcium borate coheres to as many perfect sphericles inside the bead as there are fragments of lime applied; and these sphericles are immediately resolved into one by O.P. applied to the containing bead. It is usually supposed that the two liquids, in an experiment with fluids, *must* be of '*precisely* the same specific gravity.' ('Miller's Chemical Physics,' page 65), but that is not *necessary*; for, you see, here is a sphericle of pure gold floating in the boric acid bead B.B. in exactly the same manner as the calcium borate sphericles float."

C.—"This is quite clear; and, as you have shown the contained spheroidal borates to consist of materials in *definite proportion* to each other—exceedingly interesting and important to my mind; but I do not yet see why or how *calcium silicate* forms inner balls in *calcium* borate B.B. Why does not the lime of the of the former combine with or rather join the lime of the latter, and dissolve the silica transparently in the ball, as you showed us it did when the ball was held *per se* on a platinum-wire hook B.B.?' (Lesson XI., page 590, "E.M."). "Your observation shows that you are following me closely, and this is precisely the difficulty as regards the *nature* of these inner balls, which occurred to myself. In the absence of a menstruum (at present) for dissolving the outer, and thus obtaining for examination the inner balls *per se*, which will no doubt one day be found. (Prof. G. G. Stokes, Sec. Royal Society, recommends me to try *aceticacid*, which I intend doing.) I attempted tocome to some definite conclusion regarding them by a simple process of ratiocination, and argued thus: "If" (said I to myself) "these inner balls are silico-borate of calcium, balls will be formed, when pure silica is applied to the calcium borate, held *by itself* on a platinum wire, without the containing bead of boric acid B.B.; and this we have seen (Lesson XI., page 590, 'E.M.') is *not* the case. If, on the contrary, fresh boric acid derived from the outer containing bead is *absolutely necessary* for their formation, the presumption must be that calcium borate cannot be decomposed either by separate or dissolved silica in boric acid B.B.; or, in other words, that the calcium borate will not give up any part of its proportion of boric acid to the calcium silicate in order to form inner balls, or any part of its lime to combine with the silica; and that the originally added silica, therefore, is simply dissolved in the ball *per se*, and changed in its nature through the abstraction of its 'chemical water' by the action of calcium borate at this high temperature upon it. (Lesson XI., page 590, "E. M.") The silica then gradually becomes, as it loses this water, in a manner, *itself* 'caustic,' and capable of forming, at high temperature, a fusible compound with boric acid, which compound follows the law of cohesion of liquids while fluid and undissolved in the calcium borate; just as you see this speck of hard marble, when applied B.B. to a boric acid bead, at first appears (like silica) as an unacted-upon white opaque fragment; but shortly losing its CO_2 and 'chemical water' (which latter *immediately shows itself as grey opalescence* in the bead), it forms a fusible compound, and appears as a transparent ball of calcium borate, instead of a white opaque fragment of calcium carbonate in the bead."

C.—"Hullo! Professor, do you mean to say you think you have, in the formation of these inner balls, formed a new substance, hitherto unknown to chemists—i.e., *Silicon borate?*" "Most certainly. If you do not conclude it to be that from the full consideration of these experiments and results, will you kindly afford a clue to *any other* explanation of the phenomena? I consider that not only one new substance (silicon borate) has been here proved to exist, but that another substance (pure silica, or 'rock crystal,')—although not 'new' to chemists in one sense, has been hitherto entirely misunderstood by them as to its nature (it being in reality a *hydrate*), in consequence of their solely employing, in its analysis, *hydrated* acids." C.—"What do you mean by that last expression?" "I will make you explain it to yourself. You have seen, beyond all doubt, that what I have termed 'chemical water' causes the evolution of grey opalescent matter in boric acid B.B.?" C.—"Certainly, I am quite assured of that fact." "Well, now, will you be so good as to fuse a bead of this pure boric acid upon this ring of new, clean platinum wire? Good! You observe that, when cool, it is as transparent, colourless, and refractive as the 'rock crystal' of your spectacles itself. Now, dip that bead, in a state of red-heat, into this beaker of distilled water, and heat the bead again B.B. What do you observe in it?" C.—"Nothing; the bead is lessened in bulk, in consequence of the bursting of the innumerable bubbles of steam formed, but it is now as transparent and refractive as before." "Now, mark! I pour just a little sulphuric, or nitric, or hydrochloric acid into the beaker of distilled water, and stir it well round with this perfectly clean glass rod. Be so good as to dip your red-hot bead again into this acidulated water, and, after heating B.B., and cooling, tell me the result?" C.—"The result is, faint streaks of grey, opalescent matter, which, on further heating and cooling, *render the whole bead slightly opaline*, and I see now what you mean by the expression 'hydrated acids.' It seems to me, therefore (adopting your views, which I don't say I wholly do yet), that if we treat calcium borate (or the anhydrous contained ball) *separately* with silica in a boric-acid bead B.B., the combined lime, *only during the continuance of high temperature*, has an attraction for the supposed "water" of the silica, and extracts it; itself becoming *hydro-borate* of calcium *only during the period of high temperature*, giving up the thus-obtained 'chemical water' on cooling, to the surrounding boric-acid bead, where it (the chemical water) floats undissolved as a finely-divided precipitate on becoming cold (for I see the whole bead is perfectly transparent whilst hot) which you call 'grey opalescent matter,' but which I should certainly call '*Hydrated boric acid*' ——" "My dear sir,"—"Stop a bit; I haven't done yet. If we admit all this, it seems to me to follow that, if you dissolve 'hydrated' (or ordinary) silica in calcium borate held *per se* on a platinum hook ('E.M.,' p. 590) and then treat the siliceous ball in a boric acid bead B.B., the lime of the ball, caustic in spite of its combination with boric acid *at high temperature*, and *then only* capable of forming the double combination with this water and boric acid which I will call 'Calcium hydroborate' (only existing at high temperatures) extracts the water, as in the other case, from the silica; although in *this* case, the silica being contained within the ball cannot escape into the *bead*, but there—i.e., within the ball, forms the fusible compound with boric acid obtained through the ball from the outer bead of which you speak: which, assuming the spherical shape whilst fused and liquid, in obedience to the law of cohesion, appears, finally, as 'inner balls of silicon borate'; when, of course, the containing ball would be much heavier, in spite of the opaline matter it evolved. Is this what you mean?" "My dear sir, you have expressed my meaning more clearly than I could myself." C.—"Well now, will you kindly explain, if your conclusion is correct, how it is that the silica, dehydrated (and thus rendered capable, according to your account, of forming 'silicon borate') by the calcium borate ball treated *separately* with it B.B. in a boric-acid bead, does *not* then form 'silicon borate' *separately* in the *bead*?"

"For two reasons: 1st, because the boric acid, with which the inner anhydrous silica combines, is derived from the containing ball, where it must be *absolutely anhydrous*; the ball meanwhile supplying its loss, with boric acid from the containing *bead* in exchange for the water derived from the silica; so that *a round of chemical exchange* goes on. 2nd. Because perhaps the two fused fluids, 'silicon borate' and calcium borate, are suitable for exhibiting the phenomenon of floating spheres (as oil and dilute alcohol are suitable); and the two fused fluids, 'silicon borate' and boric acid are *not* suitable (as alcohol and water are not suitable)."

C.—"Well, there is no doubt the inner balls *do* exist (and must be accounted for somehow), for I have just broken a calcium borate ball containing them in half, and placed it under the microscope; and here they are sticking out of the broken side of the hemisphere. Is silica the only substance which, thus applied, forms inner balls in calcium borate?" "Oh, dear, no: zirconia, glucina, alumina, tungstic and molybdic acid; in fact, so far as I yet know, *all 'earths' and non-volatile oxides, which do not themselves form balls in boric acid* B.B., form these inner balls. The sublimate of *antimony* forms balls in calcium borate *per se* B.B. with the evolution of 'chemical water.' But the inner balls formed by some oxides, as tungstic acid, *crystallise under continued O.P.*, and these crystals *constantly exhibit the same form;* which, as you know, is quite the contrary with borax crystals B.B." C.—"Again, this seems to me a matter of *extreme* importance." "You stated just now that I ought to call that fine precipitate, which appears as grey opalescence in the clear B. acid bead, *hydrated boric acid.* Would you suppose now that boric acid thus 'hydrated' should have changed any of its properties?" C. — "Certainly I would; and, indeed, I was just going to remark that your boric-acid beads, opaque with grey opalescent matter, seem to differ in no respect (except opalescence) from the transparent beads." "What substance, then, would you call this?" (*taking some white powder out of a bottle, and heating it on a platinum spatula under C.'s nose*), C.—"Resin; or some related hydrocarbon." "This, sir" (*fusing the powder B.B. on a pt. wire ring*), "as you see, is opaque, or *hydrated boric acid*, which apparently acquired that peculiar smell of resin by simple exposure to the air, in about a year after it was hydrated in the Royal Artillery Institution Laboratory, Woolwich, in 1873." C. (*reflectively*)—"Are you *quite certain* of this? The resinous smell on ignition is unmistakable; and yet there was certainly no inflammation, as would be the case in thus heating resin. Was this boric acid hydrated with 'water' from silica?" "No, but you see, it also rehydrates calcined lime." (*Calcining to white heat in O.P. of the hot-gas lamp a fragment of pure marble, larger than the opaque bead, upon the latter. The glowing lime slowly clarifies the bead, and, when afterwards separated from the bead, crushed, and applied to fresh pure B. acid B.B., evolves grey opalescent matter into the transparent bead*). "Follow me in this experiment, and I will now show you how this B. acid was hydrated. When I thus make a paste of *calcium hydrate* (590, XXXVII. 'E. M.'), and dry it as a large white opaque bead in gentle P.P. on this pt. wire ring (Fig. 16, p. 255, 'E. M.'), bend the long wire double, and fuse a bead of pure boric acid upon a similar ring made at the other end of the wire, holding the two beads at the bend of the wire in the forceps (Fig. 17), so that the 'flame' of the hot-gas lamp, directed upon the Ca hydrate, plays *afterwards* upon the B. acid; what is it that causes this gradual opalescence in the transparent, colourless boric acid?" C.—"Why, the 'chemical water' of the calcium hydrate; I quite understand that now; there is really no necessity to go through all this *again*." "Excuse me, sir, that is not my object; but do you observe this yellow flame emitted from the calcium hydrate whilst it is slowly calcining in O.P., and evidently *causing* the opalescence in the boric acid, by impinging steadily upon the bead, until the hydrate is perfectly calcined and begins to glow white-hot?" "What is that?" C.—"What is that yellow flame? Why, *sodium*, of course!" "Observe me now, and I will prove to you that it is *not* sodium. Taking the lime-bead off the first ring, I substitute for it a bead of sodium carbonate, and thus, allowing *its indubitable* yellow sodium flame to impinge upon the bead of opalescent boric acid; what is the result?" C.—"*The opalescence removed*, by Jove! The same cause producing opposite effects. A *reductio ad absurdum*. Against Euclid. No, this won't do at all. I admit, sir, that the *first* yellow flame *cannot possibly* be due to *sodium*." "To what, then, do you suppose it to be due?" C. (*considering*)—"Well, the yellow flame, which rendered the boric acid opalescent, certainly ceased *as soon as* the calcium hydrate was calcined, leaving anhydrous lime behind; this hydrate I have seen to similarly opalesce boric acid, leaving (as was proved by the assay balance) anhydrous calcium borate behind.—Sir, I see no other conclusion except that the *first* yellow flame is caused by the *ignition* of this 'chemical water,' as you call it." "That has been my conviction for twelve years; but you are the first man of science I could get to listen, patiently and intelligently, to my proofs. Some declared they could not understand such simple evidence. *All* (very unphilosophically, I think), laughed at me and my proofs; and said I was setting the Thames on fire, &c., &c. But I will now show you how I hydrated this boric acid with the resinous smell on ignition. Taking the bent platinum wire again, I insert in the ring next the O.P. this little roll of new clean platinum foil, simply to have a considerable quantity, or *bulk*, of platinum in contact with the blowpipe 'flame,' as it then cannot be heated beyond redness, and will consequently, *continuously* emit a yellow flame; *this* yellow flame also, as you see, renders this fresh bead of pure boric acid opalescent.

Well, before I discovered this fact, I fused about an ounce of pure, crystallised boric acid in a clean open platinum dish at a table-blowpipe in the R.A. laboratory, Woolwich, with the result of finding all my boric acid grey, opaque, and (as I thought) spoiled! I do not mean to assert that you cannot fuse boric acid in platinum *without* producing this result; but I overheated mine, keeping the platinum at a strong red heat for some two hours, and producing, therefore, an enormous amount of this *yellow flame*, which filled the dish, playing upon the boric acid all the time it was being fused. I don't remember it exhibiting this resinous smell on ignition at first, and imagine, therefore, that it was thus rendered capable of gradually absorbing more hydrogen (and, perhaps, carbon) from the air to which it was constantly exposed when the stopper of the bottle was left off. I will now show you another curious result of the supposed hydration of this boric acid. You see I have got here a stoppered bottle of grey mineral powder. It is pure crystallised *Wavellite*, lately discovered in the country of which you are so justly proud (THE STATES), but baked for a fortnight in my kitchen oven (which you now know better than to suppose would eliminate the "chemical water," and which it in fact *concentrates*), crushed, and put into this bottle. I purchased this *Wavellite* some years ago, from Henson in the Strand, because I knew it, as aluminium *hydrated* phosphate, to contain a large amount of 'chemical water,' and was curious to see what the effect would be of dissolving its fine powder B.B. in my *hydrated* boric acid, by means of the cautious addition of potassium *hydrate*. You shall now do this yourself; but first I would ask you to test the *Wavellite* for iron or other possible metallic colouring oxide, with the borax you have there, as you do not believe in my reagents."

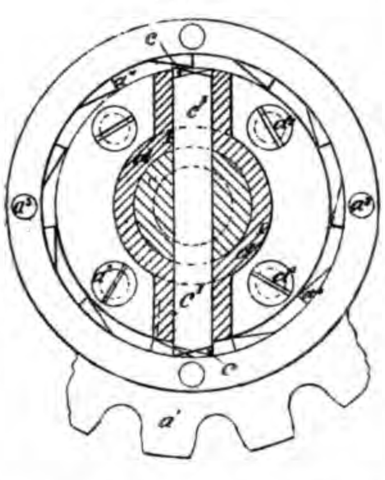
C.—"Do not say that, sir; I begin now to see the drift of what you call your system, and shall uphold it wherever I go; but I now try this powder, as you suggest, in borax B.B. for the satisfaction of others, and I find the borax bead not even yellow hot; so presume the powder to be so far free from metallic colouring oxides, that at all events, they cannot afford any recognisable colour to a bead. Now, what shall I do?" "Fuse some of the resin-smelling boric acid B.B., to a bead on this platinum wire ring, and, taking up on the hot bead gradually, some of this baked *Wavellite* powder, with a mere trace of potassium hydrate to dissolve it, treat the mass with a powerful H.P. (you know what that means now) from the 'hot-gas lamp.'" C.—"Good: the bead turns a bright purple." "Now, dip the hot bead, first in the hydrated boric acid again, and then in the *Wavellite* powder, *plus* a trace of potassium hydrate; and continue the treatment with H.P." C.—"This is really *surprising*. The bead is at first purple, then a beautiful sapphire-like *blue*, and quite transparent; then it becomes an equally brilliant emerald-like *green*!" "If you wish it to remain blue, dip it in the hydrated boric acid again." C.— "*Dark blue*, again! *All* these colours cannot possibly be due to any metallic oxide: cobalt would give a blue bead; copper or chromium a green one; and manganese a purple one; but no single oxide could produce *all three* colours. Did you not communicate this important matter to your Royal Society?" "Yes, and the Secretary sent me the materials back again, with a polite note to the effect that he had not time to try them as suggested, but power is communicated. Here, as in the previous method, it is possible by the addition of a reversed set of inclined planes and cavities to make this into a reversible clutch by a sliding arrangement which changes the balls from one circle of cavities to the other.

The chief advantages of this clutch will be found in its silence, wear, and above all in this, that, by properly adjusting the ball chambers, it can be made to give almost no backlash. It might be applied to the velocipede in the same way and in the same position as other clutches.

In a fourth method of double driving the patentee places one or more circular discs upon the treadle shaft and others to correspond upon the hub or shaft of the driving wheel or wheels, the motion being carried from the treadle shaft to the driving wheel by one or more spindles with rollers fixed on them at each end, the motion being communicated by friction. An arrangement for raising and lowering the said spindles makes a change of speed easy, and a system of this description attached to each driving wheel will give a very safe and certain method of steering the vehicle as the rider accelerates or checks the speed of either driving wheel, and in this case the third wheel of a tricycle would be made merely as a castor to carry part of the weight, not as a steering wheel, which is its usual purpose.

Fig. 1 is a front elevation, and Fig. 2 is an edge view partly in section of the first improved method of double driving. Fig. 3 is an edge view partly in section of the second method of double driving. Fig. 4 is an elevation of the outer ring with ratchet teeth, and Fig. 5 is an elevation, partly in section, through the line A B Fig. 3

FIG. 5.



In Figs. 1 and 2, *a* is the driving shaft to which is keyed or secured the bevel wheel a^1; loose upon the shaft *a* and facing the bevel wheel a^1 is a second bevel wheel *b* which forms part of the hub of one of the driving wheels. Four bevel pinions *c* are placed between and gear into both the bevel wheels a^1 and *b*. The bevel pinions *c* are fitted on studs c^1 upon which they are free to revolve: the studs c^1 are attached radially to an inner ring c^2 and are secured at the other end between the two flanges of an outer casing. This casing forms the chain wheel *d* and the brake wheel d^1, which are fastened together by the screws d^2. Motion communicated to the chain wheel *d* by the power of the rider or by any other agency will be transmitted through the bevel pinion *c* and the bevel wheels a^1 and *b* to both driving wheels.

In Figs. 3, 4 and 5, *a* is a metal disc with a boss by which it is mounted loosely up on the shaft *b* in which is cut the slot b^1. Two metal rings a^1 and a^2 are secured to the metal disc *a* by screws a^3. The ring a^1 forms the chain wheel, and the inner surfaces of the chain wheel a^1 and ring a^2 and cut in opposite directions are two rows of ratchet teeth a^4 and a^5, with an annular space a^6 between them. Two bars *c* and c^1 acting as pawls pass through the slot b^1 in the shaft *b* and are held in position by slots through two metal discs *d* and d^1 fastened together by set screws d^2: the pawls prevent the metal discs *d* and d^1 from revolving independently of the shaft *b*, but permit them to traverse the shaft to the extent of the slot b^1: the ends of these pawls *c* and c^1 are bevelled in opposite directions so as to gear with either set of ratchet teeth, and are of such length as to just miss the teeth on one side when in full gear on the opposite side, and when one pawl is in gear the other runs free in the annular space a^6: a clutch (not shown in the drawing) which takes into an annular groove d^3 in the boss of the disc *d* is employed to shift the pawls from one set of ratchet teeth to the other. By sliding the discs *d* and d^1 as far as possible in the direction of a^5 the pawl c^1 gears with the ratchet teeth a^5, and by sliding the discs as far as possible in the other direction the pawl *c* gears with the ratchet teeth a^4. If the annular space be made sufficiently wide, by placing the discs midway between a^4 and a^5 both the pawls are thrown out of gear and can revolve in the blank space a^6. The metal disc *a* and rings a^1 and a^2 may be made in one piece, and the discs *d* and d^1 may also be in one piece, if preferred. When motion is communicated from the shaft *b* to the pawls *c* and c^1 that pawl which is in gear with the ratchet teeth will transmit the motion through the chain wheel a^1 and drive the machine in one direction. By sliding the discs, the other pawl gears with the other row of ratchet teeth and drives the machine in the reverse direction.

PRACTICAL NOTES ON PLUMBING.—LXXX.*

By P. J. DAVIES, H.M.A.S.P., &c.

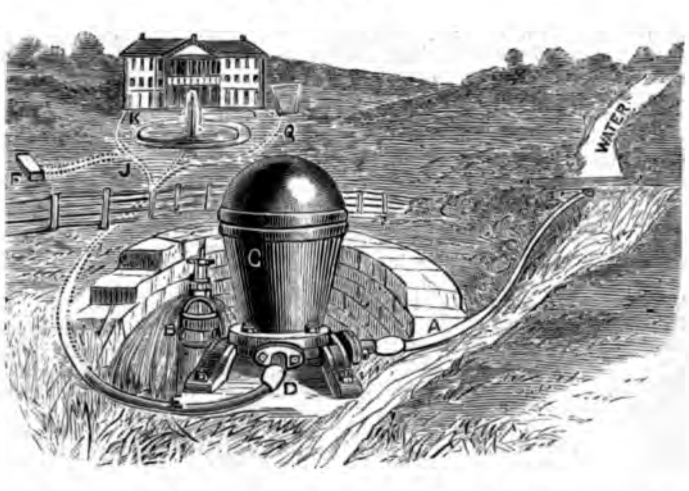
(*Continued from page* 5.)

Rams With Double Foot Valves.

ALTHOUGH I have written so much in favour of this machine, of course I do not mean to imply that we have no better, or, as far as water is concerned, no more economical machines for raising it, that is to say, *where only a limited quantity can be obtained*, or is necessary for the working of the machine itself, because if we come to that point, there is no machine equal to the overshot water-wheel, shown at Fig. 366 C, but what I wish to imply is this: that the ram is, of all water machines, the most simple, and will answer every purpose in places where large quantities of water may be had to run to waste.

The ram will work pretty well under an 18in. head of water; yet, like the water wheel, the greater the fall, and the better the supply of water applied, the more water can be thrown, and, of course, the more powerful will be the machine, though, be it understood, that it is quite possible to have too great a fall, and therefore the fall should be only in due proportion to the requirements of the machine.

FIG. 381.



The relative proportion between the water raised, and that wasted, is entirely dependent upon the fall or source of supply, that is to say, from the top of the trunk as at S to the foot-valve C, Fig. 368, and the height to which the water is required to be raised.

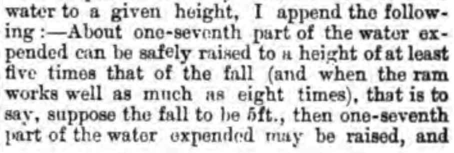
Of course, as in all cases where long lengths of pipe are used (especially when of small bore), friction must be taken into consideration.

I generally allow for rising main pipes from ½in. to 1in. bore, 1ft. pressure for every 100 yards of piping, that is to say, if the rising main be 1,000 yards long I allow 10ft. extra pressure, *or 5lbs. the square inch extra on the surface of the water in the air chamber*, to overcome the friction in such pipes. If the pipes be 1¼in. to 2in., I only allow half this amount, simply because there is not the same amount of friction in large pipes as in the smaller ones, the friction being in exact proportion to the size of bore. My advice is, always to use pipes large enough for the work.

Let us go back to the fall, and examine what is actually necessary to get a certain required amount of work. Some will say that if they had a head of say 10ft., they would make use of the whole, not having to lift the water more than 30ft. I may say that a fall of 10ft. is ample to throw one-fourteenth of the water expended to height of 140ft., and I may add that it is quite possible to fix a ram under a head of 10ft. and yet get no more work than from under a 5ft. or 6ft. head.

If this be the case, there must of necessity be a lot of useless wear and tear on an ill-proportioned ram. This being so, it requires the judgment of the plumber to select a ram which is suitable to his fall, so that the wear and tear of the machine may be in strict proportion to the amount of work done, and the economy in keeping the ram in repair will be in accordance.

FIG. 382.



In order that my readers may calculate what fall is required to safely work a ram to drive water to a given height, I append the following:—About one-seventh part of the water expended can be safely raised to a height of at least five times that of the fall (and when the ram works well as much as eight times), that is to say, suppose the fall to be 5ft., then one-seventh part of the water expended may be raised, and which will equal one-seventh part to a height of 25ft., as before said. You can get more, but this is safe reckoning. And, further, I may add that one-fourteenth part of the water expended may be raised to a height of ten times that of the fall, and so on in proportion. To make this quite clear, so that no misunderstanding may arise, I will give another illustration as follows:—If the ram be placed under a head, say, of 5ft. of water upon the trunk, then for every seven gallons drawn from the head one gallon may, and should be sent through the rising main to a height of 25ft., or half a gallon to the height of 50ft., or,

this same order of explosions by influence, which are rapidly propagated to a great number of caps.

It follows, then, from these facts, and especially from the experiments made under water, that the explosions by influence are not due to a burning, properly so called, but to the transmission of a shock arising from the enormous and sudden pressures produced by the nitro-glycerine on gun-cotton. In an extremely rapid reaction, the pressures may approach to the limit which corresponds to the matter detonating in its own volume, and the commotion due to the sudden development of almost theoretical pressures can be propagated both through the ground and by supports as intermediary or through the air itself, projected *en masse*, as has been shown by the explosion of certain powder factories and of gun-cotton magazines, and even by some of the experiments with dynamite and compressed gun-cotton. The intensity of the shock propagated either by a column of air or by a liquid or solid mass, varies with the nature of the explosive body and its mode of inflammation: it is of greater violence according as the length of the chemical reaction is shorter and develops more gas, that is to say, a higher initial pressure, and more heat, that is to say, work, for the same weight of explosive material. This transmission of a shock is conveyed better by solids than by liquids, better by liquids than by gases; with gases it is better, as they are more compressed. Through solids it is better propagated according to their degree of hardness, iron transmitting it better than earth, and hard ground better than ploughed soil. All breaks of continuity in the transmitting material tend to weaken it, especially if a softer substance is interposed. It is in this manner that the use of a tube as a receiver, made from a goose quill, stops the effect of mercury fulminate, while a tube or a capsule of copper transmits this effect in all its intensity. The explosions by influence are the better propagated in a series of cartridges according as the envelope of the first detonating cartridge is the more resisting, which allows the gases to attain a greater pressure before the covering is destroyed. The existence of an empty space, that is to say, filled with air, between the fulminate and the dynamite, on the other hand, diminishes the violence of the shock transmitted, and in consequence that of the explosion: generally the effects of breaking powders are lessened when there is no contact.

To form a full conception of the transmission of sudden pressures which produce shock by the supporting medium, it is desirable to recall this general principle, in virtue of which in a homogeneous mass, pressures are transmitted equally in all directions and are the same on a small element of surface whatever its position. Detonations produced under water with gun-cotton show that this principle is equally applicable to the sudden pressures which produce the explosive phenomena. But it ceases to be true when one passes from one medium to another.

If the inert chemical matter which transmits the explosive movement is fixed in a given situation on the surface of the ground, or better, on the surface of the rail on which the first cartridge was placed, or better still, held by the pressure of a mass of deep water, in the midst of which the first detonation is produced, the propagation of the movement in this matter will hardly be able to take place except under the form of a wave of a purely physical order, and in consequence of a character essentially different from the first wave of a chemical and physical order, at the same time developed in the explosive body itself. This new wave propagates concussion away from the explosive centre, all around it, and with an intensity which decreases inversely as the square of the distance. Even in the neighbourhood of the centre, the displacements of the molecules may break the cohesion of the mass and disperse it, or crush it by enlarging the chamber of explosion, if the operation is conducted in a cavity. But a very short distance, and of which the magnitude depends on the elasticity of the surrounding medium, these movements, confused at the beginning, regulate themselves in order to produce a wave, properly so called. Characterised by compression and sudden deformations of the material, the amplitude of these oscillations depend upon the magnitude of the initial impulse. They move with a very great rapidity, and preserve their regularity up to the point where the medium is broken. Then these compressions and sudden deformations change their nature and are transformed into a movement of impulse, that is to say, that they reproduce the shock. If then they act on a new cartridge they may determine its explosion; the shock will be otherwise weakened by the distance, and in consequence the character of the explosion may be modified. The effects diminish in this manner up to a certain point, from which the explosion ceases to produce itself.

When this occurs on a second cartridge the same series of effects will be produced from the second to the third cartridge; but they depend on the character of the explosion of the second cartridge. nd thus it goes on.

Such is the theory that appears to me to explain explosions by influence and the phenomena which accompany them. It depends, definitely, on the production of two orders of waves: one series represents the explosive waves, properly so called, developed in the midst of the matter which detonates, and consisting of a continual reproduction of the transformation of the chemical actions into caloric and mechanical action, which transmits the shock to the support and to the contiguous bodies; the other is a purely mechanical and physical series, and which also transmits the sudden pressures all round the centre of the concussion to the adjoining bodies, and by a singular circumstance to a new mass of explosive material.

A theory differing from this was originally proposed by Abel; that is to say, the theory of *Synchronous vibrations*, to which we shall now direct our attention. According to this English savant, the originating course of the detonation of an explosive lies in the synchronism, between the vibrations produced by the body which provokes the detonation, and those which the first body would produce in detonating, precisely as a violin string resounds at a distance in unison with another vibrating chord. Prof. Abel has cited the following facts in support of his theory. To begin with, the detonators appear to differ with each variety of explosive. For instance, nitrogen iodide, so susceptible to shock or friction, cannot cause the detonation of compressed gun-cotton. Nitrogen chloride, so easily exploded, will not produce the same detonation, except when ten times the weight of the necessary fulminate is used. In the same way nitro-glycerine will not produce a detonation of gun-cotton in sheets on which is placed the envelope in which it is contained. In this way nitro-glycerine up to 23·3 grains can be detonated without success. On the other hand, the inverse influence is proved; 7·75 grains of compressed gun-cotton having caused the detonation at a distance of 25mm. of nitro-glycerine wrapped up in an envelope of thin sheet iron. A cap filled with a mixture of potassium ferrocyanide and potassium chlorate, similarly (according to Brown), will not detonate gun-cotton. Finally, a cap consisting of a mixture of mercury fulminate and potassium chlorate, should be used of much heavier weight than if it were filled with the pure fulminate, (according to Franzl). Nevertheless, the heat given off by the same weight is greater by one-fifth than that with the first mixture.

Messrs. Chapman and Pellett have brought to the support of this ingenious hypothesis the following experiments: they attached to the strings of a double bass particles of nitrogen iodide, a substance which detonates on the slightest friction. Then they made the strings of a similar instrument vibrate at a short distance off. A detonation was produced, but only for sounds higher than a certain note, which corresponds to 60 vibrations per second. They also took two conjugate parabolic mirrors placed 2·5 meters apart and they arranged along the line of foci at different points several drops of nitro-glycerine or of nitrogen-iodide; then they detonated at one of the foci a large drop of nitro-glycerine; they observed that the explosive substances placed in the conjugated foci detonated in unison to the exclusion of the same substances placed at other points. A layer of lampblack placed on the surface of the mirrors was designed to prevent the reflection and the concentration of the calorific rays.

As yet none of the experiments appear to me to be conclusive, and several of them seem even to be formally opposed to the theory. We shall begin by observing that the speciality of a given musical note, capable of determining each variety of explosion, has never been established; it is only below a certain note that the effects cease to be produced, while they take place by preference, and whatever the explosive bodies may be, by the action of the most acute notes. Besides, these effects cease to produce themselves at distances which are incomparably less than the resources of the chords in unison, which goes to prove that the detonations are functions of the intensity of the mechanical action, rather than of the character itself of the determining vibration. Similarly, the detonation ceases to be produced when the weight of the detonator is too slight, and in consequence when the living force of the shock is weakened. Nevertheless, the special vibratory note which determines the explosions should always remain the same. For instance, cartridges filled with 75 per cent. of dynamite cease to detonate when the capsule contains a weight of fulminate less than 0·2 grains; the detonation not being certain in all cases except by the regulation weight of one grain. This confirms the existence of a direct relation between the character of the detonation and the intensity of the shock produced by one and the same detonator. If it is true that gun-cotton will cause the nitro-glycerine to detonate in consequence of the synchronism of the vibration communicated, then we do not understand why the reciprocal action does not take place, while the absence of reciprocity can be easily explained by the difference of the structure of the two substances which play so important a part in the transformation of the living force into work.

This same diversity of structure and the modifications which it introduces into the transmission of the phenomena of shock and with the transformation of mechanical energy into caloric energy, may be called upon to explain the facts observed by Abel. The difference between the energy of pure fulminate and of the fulminate mixed with potassium chlorate is no less easily explained; the shock produced by the first body being sharper on account of the absence of all dissociation of the product, which is no other than carbon monoxide, this absence should be opposed to the dissociation of carbon dioxide formed in the second case. Perhaps, also, the formation of potassium chloride disseminated through the gas produced with the aid of potassium chlorate weakens the shock, just the same as silicon does in the case of dynamite.

All the effects observed with the nitrogen-iodide may be explained by the vibration of the supports and by the effects of rubbing which results therefrom, this substance being particularly sensitive to friction. The experiment with the conjugate mirrors may also be easily explained by the concentration in the foci of the movements of the air, and therefore of the mechanical effects which result. Besides, M. Lambert has proved by experiments made for the commission of explosive substances, that the explosion of dynamite cartridges being produced in tubes of cast iron of large diameter, it does not appear to have, from the standpoint of detonations provoked by influence, any difference between the vibratory motions and nodes characteristic of the tube. Desiring to clear up this entire question by removing it from the influence of the supports and of the diversity of cohesion and physical structure of solid explosive substances, I undertook a series of special experiments on the chemical stability of matter in a sonorous vibration and especially on that of gaseous bodies such as ozone or hydrogen, arsenide or liquids, such as hydrogen feroxide, or persulphuric acid, all of the bodies being selected from among those which decompose or change spontaneously, and that at ordinary temperatures with the disengagement of heat, precisely similar to explosive substances. The description of these experiments may be found in the *Comptes Rendus* or in the *Revue Scientifique*, May, 1880. They lead to the conclusion that substances which are transformable with the disengagement of heat, are stable under the influence of soundwaves, while they are decomposed under the influence of ethereal vibrations. This diversity in the mode of action of the two classes of vibrations is not surprising when we consider that the sharpest sonorous vibrations are incomparably slower than the luminous or calorific vibrations.

Nevertheless, it appears certain that the propagation of explosions by influence is not made in virtue of an undulatory movement, a complex movement of a chemical and physical order in the midst of the explosive substance which is decomposed, whilst it is purely physical in the midst of intermediary substances which suffer no decomposition. But that which distinguishes this sort of movement of the vibrations, properly so called, is, first of all, its extreme intensity; that is to say, the magnitude of the living force which it transmits; it is also the unique character of the explosive wave, which is propagated in opposition to the multiplicity of successive sonorous waves. Finally it is essential to observe that the explosive material does not detonate because it transmits the movement, but on the contrary because it arrests, and because it transforms on the spot the mechanical energy into calorific energy capable of suddenly raising the temperature of the substance up to the degree which will produce its decomposition.

MOULDING A JACKETED CYLINDER.*

At the left of the engraving is shown a section of a jacketed cylinder, which will be recognized by the practised moulder as being a somewhat difficult casting to make. The outside of the casting is a simple affair enough, the difficulties being confined almost entirely to the centre core, which is shown in section on the right, together with the sweep and other accessories used in its making.

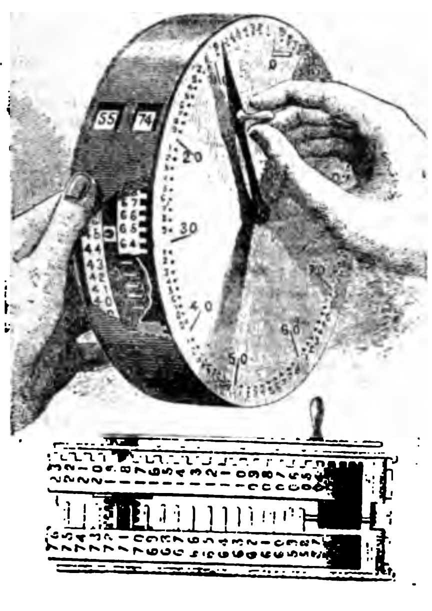
In making the mould the outside was made first, not because it is customary to do so, but because it it had to be built up and dried in a pit, from a lack of oven room. At K is shown the bottom plate; also a holding down hook, of which there are four. The plate was set on a solid sand foundation, and in order to leave a pit below a cast-iron ring F was used. The pit was required to provide room for a man to operate screws for centring the centre core, as will be explained further on.

In making the outside mould there were five 6in. round blocks distributed so as to equally divide the circumference, for making vent holes as at H. At mechanically added. Through the centre of the case extends a shaft, and on the face of the case, in a circle drawn from the shaft centre, are inscribed a series of figures, from 0 to 99, inclusive, consecutively, as shown, and rigidly secured to the front end of the shaft is a hand or pointer, which is kept in its initial position at 0 against a stop by a coiled spring. Two circular discs mounted loosely on the shaft are peripherally numbered. The disc which registers units and tens is provided with a flange on the inside of which are cut ratchet teeth, which register with and correspond in number to the numbers on the periphery of the discs. Into these ratchet teeth a spring pawl which is secured to the arm catches. When the pointer is turned to the right, the disc remains stationary; but when the pointer is turned to the left, the pawl engages with one of the ratchet teeth and revolves the disc with the shaft. The second disc is loosely mounted upon the shaft at a suitable distance from the first disc and, like it, is peripherally numbered. Projecting from its inner face are a hundred tappet pins, which register with the numbers inscribed upon the periphery.

---

* By Thos. D. West, in the American Machinist.

The first disc is provided with a spring tappet rod which projects from its outer face, and is so situated as to be normally out of contact with the tappet pins on the second disc. This tappet rod moves the second disc one number each time it is brought into operation. The normal position of the machine is when the pointer is at 0 and the ciphers on the discs register with the apertures in the case. In adding a number of figures—as, for example, 20, 17, and, 13—the pointer will be turned from 0 on the dial to the left until it reaches 20, and then released, and the spring, E, allowed to carry back to 0, then to the left again to 17, and so on for the next number, and, owing to the pawl and ratchet teeth previously described, the disc, F, will be revolved from point to point, and the sum "50" will appear through the units and tens aperture. When the sum of the figures added equals or exceeds 100, the second disc will be also moved one point, or as many times as there are hundreds in the sum, and the amount will be read through both apertures, as will be very readily understood.—*Scientific American.*



SOME UNSOLVED PROBLEMS IN GEOLOGY.

THE American Association for the Advancement of Science held its annual meeting at Minneapolis, in August last, and as usual the retiring president delivered an address, of which the following is an abstract. After some preliminary remarks in which he pointed out that science must be limited on all sides by unsolved mysteries, Principal Dawson, LL.D., F.R.S., commenced his subject by asking:—

What do we know of the oldest and most primitive rocks? At this moment the question may be answered in many and discordant ways; yet the leading elements of the answer may be given very simply. The oldest rock formation known to geologists is the lower Laurentian, the fundamental gneiss, the Lewisian formation of Scotland, the Ottawa gneiss of Canada. This formation of enormous thickness corresponds to what the older geologists called the fundamental granite,—a name not to be scouted, for gneiss is only a stratified granite. Perhaps the main fact in relation to this old rock is that it is a gneiss; that is, a rock at once bedded and crystalline, and having for its dominant ingredient the mineral orthoclase—a compound of silica, alumina, and potash—in which are imbedded, as in a paste, grains and crystals of quartz and hornblende. We know very well, from its texture and composition, that it cannot be a product of mere heat; and being a bedded rock, we infer that it was laid down layer by layer, in the manner of aqueous deposits. On the other hand, its chemical composition is quite different from that of the muds, sands, and gravels usually deposited from water. Their special characters are caused by the fact that they have resulted from the slow decay of rocks like these gneisses, under the operation of carbonic acid and water, whereby the alkaline matter and the more soluble part of the silica have been washed away, leaving a residue mainly siliceous and aluminous. Such more modern rocks tell of dry land subjected to atmospheric decay and rainwash. If they have any direct relation to the old gneisses, they are their grandchildren, not their parents. On the contrary, the oldest gneisses show no pebbles, or sand, or limestone—nothing to indicate that there was then land undergoing atmospheric waste, or shores with sand and gravel. For all that we know to the contrary, these old gneisses may have been deposited in a shoreless sea, holding in solution or suspension merely what it could derive from a submerged crust recently cooled from a state of fusion; still thin, and exuding here and there through its fissures heated waters and volcanic products.

It is scarcely necessary to say that I have no confidence in the supposition of unlike composition of the earth's mass on different sides, on which Dana has partly based his theory of the origin of continents. The most probable conception seems to be that of Lyell; namely, a molten mass, uniform except in so far as denser material might exist toward its centre, and a crust, at first approximately even and homogeneous, and subsequently thrown into great bendings upward and downward.

In short, the fundamental gneiss of the lower Laurentian may have been the first rock ever formed; and in any case it is a rock formed under conditions which have not since recurred, except locally. It constitutes the first and best example of these chemico-physical, aqueous, or aqueo-igneous rocks, so characteristic of the earliest period of the earth's history. Viewed in this way, the lower Laurentian gneiss is probably the oldest kind of rock we shall ever know—the limit to our backward progress, beyond which there remains nothing to the geologist except physical hypotheses respecting a cooling, incandescent globe.

In the next succeeding formation, the true lower Laurentian of Logan, the Grenville series of Canada, we meet with a great and significant change. It is true, we have still a predominance of gneisses which may have been formed in the same manner with those below them: but we find these now associated with great beds of limestone and dolomite, which must have been formed by the separation of calcium and magnesium carbonates from the sea water, either by chemical precipitation or by the agency of living beings. We have also quartzite, quartzose gneisses, and even pebble beds, which inform us of sandbanks and shores. Nay, more, we have beds containing graphite, which must be the residue of plants, and iron ores which tell of the deoxidation of iron oxide by organic matters. In short, here we have evidence of new factors in world-building,—of land and ocean, of atmospheric decay of rocks, of deoxidising processes carried on by vegetable life on the land and in the waters, of limestone-building in the sea. To afford material for such rocks, the old Ottawa gneiss must have been lifted up into continents and mountain masses. Under the slow but sure action of the carbonic dioxide dissolved in rain-water, its felspar had crumbled down in the course of ages. Its potash, soda, lime, magnesia, and part of its silica, had been washed into the sea, there to enter into new combinations, and to form new deposits. The crumbling residue of fine clay and sand had been also washed down into the borders of the ocean, and had been there deposited in beds. Thus the earth had entered into a new phase, which continues onward through the geological ages; and I place in your hands one key for unlocking the mystery of the world when I affirm that this great change took place, this new era was inaugurated, in the midst of the Laurentian period.

This is also a proper place to say something of the doctrine of what is termed "metamorphism." The Laurentian rocks are undoubtedly greatly changed from their original state, more especially in the matters of crystallisation and the formation of disseminated minerals by the action of heat and heated water. Sandstones have thus passed into quartzites, clays into slates and schists, limestones into marbles. So far, metamorphism is not a doubtful question; but, when theories of metamorphism go so far as to suppose an actual change of one element for another, they go beyond the bounds of chemical credibility; yet such theories of metamorphism are often boldly advanced, and made the basis of important conclusions.

The Grenville series, or middle Laurentian, is succeeded by what Logan in Canada called the upper Laurentian, and which other geologists have called the Norite or Norian series. Here we still have our old friends the gneisses, but somewhat peculiar in type; and associated with them are great beds rich in lime-felspar,—the so-called labradorite and anorthite rocks. The precise origin of these is uncertain, but this much seems clear: namely, that they originated in circumstances in which the great limestones deposited in the lower or middle Laurentian were beginning to be employed in the manufacture, probably by aqueo-igneous agencies, of lime-felspars. This proves the Norian rocks to be much younger than the Laurentian, and that, as Logan supposed, considerable earth-movements had occurred between the two, implying lapse of time.

Next we have the Huronian of Logan,—a series much less crystalline and more fragmentary, and affording more evidence of land elevation and atmospheric and aqueous erosion than any of the others.

Still later than the Huronian is the great micaceous series called by Hunt the Mont Alban or White Mountain group, and the Taconian or Taconic of Emmons, which recalls in some measure the conditions of the Huronian. The precise relations of these to the later formations, and to certain doubtful deposits around Lake Superior, can scarcely be said to be settled, though it would seem that they are all older than the fossiliferous Cambrian rocks which practically constitute the base of the Palæozoic.

After what has been said, you will perhaps not be astonished that a great geological battle rages over the old crystalline rocks. By some geologists they are almost entirely explained away, or referred to igneous action or to the alteration of ordinary sediments. Under the treatment of another school, they grow to great series of pre-Cambrian rocks, constituting vast systems of formations, distinguishable from each other, not by fossils, but by differences of mineral character.

After the solitary appearance of Eozoon in the Laurentian, and of a few uncertain forms in the Huronian and Taconian, we find ourselves in the Cambrian, in the presence of a nearly complete invertebrate fauna of protozoa, polyps, echinoderms, molluscs, and crustacea; and this not confined to one locality merely, but apparently extending simultaneously throughout the ocean. This sudden incoming of animal life, along with the subsequent introduction of successive groups of invertebrates, and finally of vertebrate animals, furnishes one of the greatest of the unsolved problems of geology, which geologists were wont to settle by the supposition of successive creations. In an address delivered at the Detroit meeting of the Association in 1875, I endeavoured to set forth the facts as to this succession, and the general principles involved in it, and to show the insufficiency of the theories of evolution suggested by biologists to give any substantial aid to the geologist in these questions. In looking again at the points there set forth, I find they have not been invalidated by subsequent discoveries, and that we are still nearly in the same position with respect to these great questions that we were in at that time,—a singular proof of the impotency of that deductive method of reasoning which has become fashionable among naturalists of late. Yet the discussions of recent years have thrown some additional light on these matters; and none more so than the mild disclaimers with which my friend Dr. Asa Gray and other moderate and scientific evolutionists have met the extreme views of such men as Romanes, Haeckel, Lubbock, and Grant Allen. It may be useful to note some of these as shedding a little light on this dark corner of our unsolved problems.

It has been urged, on the side of rational evolution, that this hypothesis does not profess to give an explanation of the absolute origin of life on our planet, or even of the original organisation of a single cell or of a simple mass of protoplasm, living or dead. All experimental attempts to produce by synthesis the complex albuminous substances, or to obtain the living from the non-living, have so far been fruitless; and, indeed, we cannot imagine any process by which such changes could be effected. That they have been effected we know; but the process employed by their Maker is still as mysterious to us as it probably was to him who wrote the words, "And God said, Let the waters swarm with swarmers." How vast is the gap in our knowledge and our practical power implied in this admission, which must, however, be made by every mind not absolutely blinded by a superstitious belief in those forms of words which too often pass current as philosophy.

But if we are content to start with a number of organisms ready made—a somewhat humiliating start, however—we still have to ask, How do these vary so as to give new species? It is a singular illusion in this matter, of men who profess to be believers in natural law, that variation may be boundless, aimless, and fortuitous, and that it is by spontaneous selection from varieties thus produced that development arises. But surely the suppos that of mere chance and magic is unworthy of science. Varieties must have causes, and their causes and their effects must be regulated by some law or laws. Now, it is easy to see that they cannot be caused by a mere innate tendency in the organism itself. Every organism is so nicely equilibrated, that it has no such spontaneous tendency, except within the limits set by its growth and the law of its periodical changes. There may, however, be equilibrium more or less stable. I believe all attempts hitherto made have failed to account for the fixity of certain, nay, of very many, types throughout geological time; but the mere consideration that one may be in a more stable state of equilibrium than another so far explains it. A rocking stone has no more spontaneous tendency to move than an ordinary boulder, but it may be made to move with a touch. So it probably is with organisms. But, if so, then the causes of variation are external, as in many cases we actually know them to be; and they must depend on instability or change in surroundings, and this so arranged as not to be too extreme in amount, and to operate in some determinate direction. Observe how remarkable the unity of the adjustments involved in such a supposition. How superior they must be to our rude and always more or less unsuccessful attempts to produce and carry forward varieties and races in definite directions! This cannot be chance. If it exists, it must depend on plans deeply laid in the nature of things, else it would be most monstrous magic and causeless miracle. Still more certain is this conclusion when we consider the vast and orderly succession made known to us by geology, and which must have been regulated by fixed laws, only a few of which are as yet known to us.

Certain recent utterances of eminent scientific men in England and France are most instructive with reference to the difficulties which encompass this subject. Huxley, at present the leader of English evolutionists, in his "Rede Lecture" delivered at Cambridge, England, holds that there are only two "possible alternative hypotheses" as to the origin of species—(1) that of "construction," or the mechanical putting-together of the materials and parts of each new species separately; and (2) that of "evolution,,' or that one form of life "proceeded from another" by the "establishment of small successive differences." After comparing these modes, much to the disadvantage of the first, he concludes with the statement that "this was his case for evolution, which he rested wholly on arguments of the kind he had adduced"; these arguments being the threadbare false analogy of ordinary reproduction and the transformation of species, and the mere succession of forms more or less similar in geological time, neither of them having any bearing whatever on the origin of any species or on the cause of the observed succession. With reference to the two alternatives, while it is true that no certain evidence has yet been obtained—either by experiment, observation, or sound induction—as to the mode of origin of any species, enough is known to show that there are numerous possible methods, grouped usually under the heads of absolute creation, mediate creation, critical evolution, and gradual evolution. It is also true that almost the only thing we certainly know in the matter is that the differences characteristic of classes, orders, genera, and species, must have arisen, not in one or two, but in many ways. An instructive commentary on the capacity of our age to deal with these great questions is afforded by the fact that this little piece of clever mental gymnastics should have been practised in a university lecture and in presence of an educated audience. It is also deserving of notice, that, though the lecturer takes the development of the Nautili and their allies as his principal illustration, he evidently attaches no weight to the argument in the opposite sense deduced by Barrande—the man of all others most profoundly acquainted with these animals—from the palæozoic cephalopods.

Another example is afforded by a lecture recently delivered at the Royal Institution in London by Professor Flower. The subject is "The Whales, Past and Present, and their Probable Origin." He gives up at once, as every anatomist must, the idea of an origin from fishes or reptiles. He thinks the ancestors of the whales must have been quadrupedal mammals. He is obliged for good reasons to reject the seals and the otters, and turns to the ungulates, though here, also, the difficulties are formidable. Finally he has recourse to an imaginary ancestor, supposed to have haunted marshes and rivers of the Mesozic age, and to have been intermediate between a hippopotamus and a dolphin, and omnivorous in diet. As this animal is altogether unknown to geology or zoology, and not much less difficult to account for than the whales themselves, he very properly adds, "Please to recollect, however, that his is a mere speculation"

Another caution which a paleontologist has occasion to give with regard to theories of life has reference to the tendency of biologists to infer that animals and plants were introduced under embryonic forms, and at first in few and imperfect species. *Facts do not substantiate this. The first appearance* of leading types of life is rarely embryonic. On the contrary, they often appear in highly perfect and specialised forms; often, however, of composite type, and expressing characters afterwards so separated as to belong to higher groups. The trilobites of the Cambrian are some of them of few segments, and, so far, embryonic; but the greater part are many-segmented, and very complex. The batrachians of the carboniferous present many characters higher than those of their modern successors, and now appropriated to the true reptiles. The reptiles of the Permian and trias usurped some of the prerogatives of the mammals. The ferns, lycopods, and equisetums of the Devonian and Carboniferous were, to say the least, not inferior to their modern representatives. The shell-bearing cephalopods of the Palæozoic would seem to have possessed structures now special to a higher group, that of the cuttle-fishes. The bald and contemptuous negation of these facts by Haeckel and other biologists does not tend to give geologists much confidence in their dicta.

There is one other unsolved problem, in the study of life by the geologist, to which it is still necessary to advert. This is the inability of palæontology to fill up the gaps in the chain of being. In this respects, we are constantly taunted with the imperfection of the record; but facts show that this is much more complete than is generally supposed. Over long periods of time and many lines of being we have a nearly continuous chain; and, if this does not show the tendency desired, the fault is as likely to be in the theory as in the record. On the other hand, the abrupt and simultaneous appearance of new types in many specific and generic forms, and over wide and separate areas at one and the same time, is too often repeated to be accidental. Hence palæontologists, in endeavouring to establish evolution, have been obliged to assume periods of exceptional activity in the introduction of species, alternating with others of stagnation—a doctrine differing very little from that of special creation as held by the older geologists.

So soon as we find evidence of continents and oceans, we raise the question, "Have these continents existed from the first in their present position and form, or have the land and water changed places in the course of geological time? In reality both statements are true in a certain limited sense. On the one hand, any geological map whatever suffices to show that the general outline of the existing land began to be formed in the first and oldest crumplings of the crust. On the other hand, the greater part of the surface of the land consists of marine sediments which must have been derived from land that has perished in the process, while all the continental surfaces, except, perhaps, some high peaks and ridges, have been many times submerged. Both of these apparently contradictory statements are true; and, without assuming both, it is impossible to explain the existing contours and reliefs of the surface.

In the case of North America, the form of the old nucleus of Laurentian rock in the north already marks out that of the finished continent, and the successive later formations have been laid upon the edges of this, like the successive loads of earth dumped over an embankment. But in order to give the great thickness of the Palæozoic sediments, the land must have been again and again submerged, and for long periods of time. Thus, in one sense, the continents have been fixed; in another, they have been constantly fluctuating.

The causes and mode of operation of the great movements of the earth's crust which have produced mountains, plains, and tablelands, are still involved in some mystery. One patent cause is the unequal settling of the crust towards the centre; but it is not so generally understood as it should be that the greater settlement of the ocean bed has necessitated its pressure against the sides of the continents in the same manner that a huge icefloe crushes a ship or a pier. The geological map of North America shows this at a glance, and impresses us with the fact that large portions of the earth's crust have not only been folded, but bodily pushed back for great distances. On looking at the extreme north, we see that the great Laurentian mass of central Newfoundland has acted as a protecting pier to the space immediately west of it, and has caused the Gulf of St. Lawrence to remain an undisturbed area since Palæozoic times. Immediately to the south of this, Nova Scotia and New Brunswick are folded back. Still farther south, as Guyot has shown, the old sediments have been crushed in sharp folds against the Adirondack mass, which has sheltered the tableland of the Catskills and of the Great Lakes. South of this again, the rocks of Pennsylvania and Maryland have been driven back in a great curve to the west. Nothing, I think, can more forcibly show the enormous pressure to which the edges of the continents have been exposed, and at the same time the great sinking of the ocean beds. Complex and difficult to calculate though these movements of plication are, they are more intelligible than the apparently regular pulsations of the flat continental areas, whereby they have alternately been below and above the waters, and which must have depended on somewhat regular recurring causes, connected either with the secu cooling of the earth, or with the gradual retar tion of its rotation, or with both. Throughout t changes, each successive elevation exposed rocks for long ages to the decomposing influenc the atmosphere. Each submergence swept aw and deposited as sediment, the material accumula by decay. Every change of elevation was acco panied with changes of climate and with mod cations of the habitats of animals and plants. W it possible to restore accurately the phys geography of the earth in all these respects, for e geological period, the data for the solution of m difficult questions would be furnished.

Principal Dawson then spoke of the controv with regard to the formation of coal, and of respecting the so-called fucoids of the ancient ro He then gave the landmarks of the great Gla epoch, and proceeded:—

No conclusions of geology seem more certain t that great changes of climate have occurred in course of geological time; and the evidence of in that comparatively modern period which mediately preceded the human age is so stri that it has come to be known as pre-eminently ice age, while, in the preceding tertiary peri temperate conditions seem to have prevailed e to the Pole. Of the many theories as to t changes which have been proposed, two seem present to divide the suffrages of geologists, ei alone, or combined with each other. These (1) the theory of the precession of the equinoxe connection with the varying eccentricity of earth's orbit, advocated more especially by Cr and (2) the different distribution of land and w as affecting the reception and radiation of heat the ocean currents,—a theory ably propounded Lyell, and subsequently extensively adopted, ei alone or with the previous one. One of these vi may be called the astronomical; the other, geographical.

If, however, we are to adopt the geograph theory, we must avoid extreme views; and leads to the inquiry as to the evidence to be fo for any such universal and extreme glaciation demanded by some geologists.

The only large continental area in the north hemisphere supposed to be entirely ice and sn clad is Greenland; and this, so far as it goes certainly a local case, for the ice and snow Greenland extend to the south as far as 60° latitude, while both in Norway and in the inte of North America the climate in that latitude mits the growth of cereals. Further, Grin Land, which is separated from North Greenl only by a narrow sound, has a comparatively climate, and, as Nares has shown, is covered verdure in summer. Still further, Nordenskj one of the most experienced Arctic explorers, that it is probable that the interior of Greenlan itself verdant in summer, and is at this mom preparing to attempt to reach this interior o Nor is it difficult, with the aid of the facts cite Woeikoff and Whitney, to perceive the cause of exceptional condition of Greenland. To giv and snow in large quantities, two conditions required,—first, atmospheric humidity; secondly, cold precipitating regions. Both of t conditions meet in Greenland. Its high co ranges receive and condense the humidity from sea on both sides of it and to the south. Hence vast accumulation of its coast snow-fields, and intense discharge of the glaciers emptying out o valleys. When extreme glacialists point to Gre land, and ask us to believe that in the glacial the whole continent of North America as far so as the latitude of 40° was covered with a contine glacier, in some places several thousands of thick, we may well ask, first, what evidence t is that Greenland, or even the Antartic contin at present shows such a condition; and, secon whether there exists a possibility that the inte of a great continent could ever receive so large amount of precipitation as that required. So as present knowledge exists, it is certain that meteorologist and the physicist must answer questions in the negative. In short, perpe snow and glaciers must be local, and canno continental, because of the vast amount of poration and condensation required. These only be possible where comparatively warm supply moisture to cold and elevated land; and supply cannot, in the nature of things, penet far inland. The actual condition of interior and interior America in the higher northern latitu affords positive proof of this. In a state of pa submergence of our northern continents, we readily imagine glaciation by the combined ac of local glaciers and great ice-floes; but, in wh ever way the phenomena of the boulder clay an the so-called terminal moraines are to be accou for, the theory of a continuous continental gla must be given up.

Recently the opinion has been gaining gro that the close of the ice age is very recent. reasons as the following lead to this conclus the amount of atmospheric decay of rocks an denudation in general, which have occurred the close of the glacial period, are scarcely preciable; little erosion of river-valleys or of coast-terraces has occurred. The calculated recession of waterfalls and of production of lake-ridges leads to the same conclusion. So do the recent state of bones and shells in the Pleistocene deposits, and the perfectly modern species of their fossils. On such evidence the cessation of the glacial cold and settlement of our continents at their present levels are events which may have occurred not more than six thousand or seven thousand years ago, though such time estimates are proverbially uncertain in geology. This subject also carries with it the greatest of all geological problems, next to that of the origin of life; namely, the origin and early history of man. Such questions cannot be discussed in the closing sentences of an hour's address. I shall only draw from them one practical inference. Since the comparatively short post-glacial and recent periods apparently include the whole of human history, we are but new-comers on the earth, and therefore have had little opportunity to solve the great problems which it presents to us. But this is not all. Geology as a science scarcely dates from a century ago. We have reason for surprise in these circumstances that it has learned so much, but for equal surprise that so many persons appear to think it a complete and full-grown science, and that it is entitled to speak with confidence on all the great mysteries of the earth that have been hidden from the generations before us. Such being the newness of man and of his science of the earth, it is not too much to say that humility, hard work in collecting facts, and abstinence from hasty generalisation, should characterise geologists, at least for a few generations to come.

SILVER PRINTS MOUNTED ON GLASS—MEDALLIONS, AND HOW TO PRODUCE THEM.*

TWENTY years have elapsed since Mr. Rawlinson, as well as Mr. Tunny in Scotland, mounted photographs on glass plates by means of gelatine, much in the same manner as we practise the process to-day; and shortly afterwards Mr. V. Blanchard described his method of stripping the photograph from a glass plate previously collodionised. The method proposed by the latter gentleman has been in use all over the civilised world almost daily since its publication, but the former was allowed to lie dormant, or nearly so, until the energy of Mr. Payne Jennings and a few other exhibitors brought it once more to the fore. Briefly, the prints to be treated should be printed darker than for ordinary mounting, care being taken not to tone them very much, or a cold blue or grey tone will be the result when finished. The glass plate intended for the reception of the print should be free from scratches or blisters, and must be most carefully polished with rouge, tripoli, or the usual polishing mixture. It is then placed on a water oven or heated over a gas-flame or other contrivance, until it can be comfortably borne on the back of the hand. Hot gelatine solution—1 part gelatine to 15 parts water—should next be poured in a pool on the warm plate, and equally distributed over its surface by means of a glass rod; the prints, which are slightly smaller than the glass plate, are withdrawn from a weak solution of gelatine (1 part gelatine to 40 parts of water) and placed, albumenised side downwards, on the gelatinised glass plate, when it will be found that a good squeegeeing will remove the excess. When dry, the operation is complete. As a matter of fact, so largely have photographers availed themselves of this method of exhibiting their own productions, that it would be difficult to find a place of importance where the process is not employed. And here we may mention that we have noticed, in a few instances where show-cases have been exposed to considerable variations of temperature, including the full force of the sun's rays, portions of the photographs have dragged away from the glass support, and in a short time showed unmistakable signs of fading, while the parts still adhering appeared comparatively fresh. There is always a danger of the print coming up in patches unless the glass plate is thoroughly well polished, and as the instances we speak of were all pictures of large size, doubtless the defect was due to imperfect polishing.

A further development of this process is to be seen in the medallions, as they are called; that is to say, photographs surrounded with black varnish and a metal rim.

By abrading the back of the print with fine glass paper, as recommended in the crystoleum process, it is possible, especially with landscapes, to produce a certain amount of coloured effects by means of liquid dyes in alcohol, and in many cases we have seen good results. When portraits, however, are so treated, they are seldom all that can be desired, the main difficulty being to get the proper depth of tint. The only difficulty likely to be encountered in the production of these pictures will be with the gelatine. Temperature, as in carbon printing, play an important part. 65° F. will be found the most satisfactory temperature for the coating and drying-room, and every precaution should be taken to obtain that result, or failures are sure to follow. Having regulated the temperature, the following articles will be required:—A flat tin dish for dissolving the gelatine, arranged over a Fletcher air burner gas-stove, and a similar dish for soaking the prints in the melted and filtered gelatine: also a jug for pouring the solution over the glass plate, arranged over a fine jet of sufficient heat to prevent the solution cooling; a Wedgwood funnel, into the neck of which is placed a piece of clean wet sponge, answers well for filtering; a glass rod for distributing the gelatine over the plate; a rubber squeegee, and a piece of American cloth to protect the print while squeegeeing; strips of wood an inch broad, of any length, two such strips joined by cross-pieces forming racks for drying; padded blocks of the same size and shape as the medallions will be useful (the pad forms a cushion for the glass, while the raised surface allows of passing the burnishing tool quickly round when fastening down the rim); a stock of prints trimmed to the desired size and shape. In the majority of cases, from one to two inches margin of clear glass is allowed, this margin being afterwards filled in with Bate's dead-black varnish, as described below. A stock of oval dome-top or other shape glasses; suitable backs for these shapes fitted with rings; metal rims to fit: Bates' dead-black varnish; Young's patent size, as sold at the oilman's, completes the list.

Melting the gelatine:—Cover the bottom of the tin with size broken up into small pieces. Enough cold water is poured over to cover the pieces, when the temperature is raised to nearly 200° Fahrenheit, to insure perfect solution. When melted, a portion of the solution is passed through the sponge into the second dish for soaking the prints, and the remaining portion is passed into the jug, and kept hot by the means above stated. A well-polished plate is heated to 100° F., placed on a level slab, and covered with a pool of hot size. Should the solution prove refractory, the glass rod will assist spreading. Quickly transfer a soaked print from the second dish of hot size to its position, face down, on the plate, and roughly squeegee; remove the excess with a sponge, and again apply the squeegee, this time interposing a piece of American cloth to protect the print. If no air-bells are seen when examined from the front, the plate is placed on the rack to dry, paper side uppermost, which in a good current of dry air will occupy a couple of hours. When dry, the back should receive a second coating in like manner, another two hours being required before the next operation. When the second coating is quite dry, a brush well charged with Bates' black is passed round the margin, completely coating the bare glass, care being exercised not to allow the varnish to overlap the photograph more than is really necessary; thirty minutes' drying will remove the last traces of tackiness, and no more remains to be done than to fit the back, adjust the metal rim, and secure it down neatly with a burnishing tool to the padded block.

Landscapes and figure studies, nicely vignetted to the edge of the plate, are very effective when mounted as described above, on oval glass plates, in which case the use of black varnish is, of course, dispensed with.

Mason Science College.—The Mason Science College, which begins its new session on the 23rd of October, was open three years ago, and during the first session 95 students (65 males and 30 females) were registered. In the session just ended there were 366 students (229 males and 137 females). The courses of instruction are framed with a view to prepare students for the various examinations in arts and in science of the University of London. At the same time a large number of students are pursuing different branches of science with a view to their application to manufacturing or other purposes. By an arrangement with Queen's College (the Birmingham Medical School) all their students attend this college for the purpose of obtaining instruction in chemistry, botany, and physiology. At the end of the first term (February, 1881) there were about 3,000 volumes in the library. At the present time there are upwards of 14,000 volumes, including the best works for each department of the college. The council have spared no expense in acquiring apparatus and specimens in order adequately to illustrate the various courses of lectures.

THE most successful makers of malleable castings in the United States use pig that is very free from phosphorus or sulphur, as either hot shortness or cold shortness will spoil the castings. The metal is melted in crucibles of 50lb. to 100lb. capacity, keeping the air out. The metal should be hot enough for a drop withdrawn on an iron bar to burn on exposure to the air. The cementation is done in iron boxes, the castings being bedded in powdered hematite or in iron peroxide, and kept from three to fifteen days, according to thickness. This is a greater length of time than is found necessary in this country.

SCIENTIFIC NEWS.

FROM Dun Echt Circular, No. 78, we learn that a telegram was received from Prof. Kruger at 9 a.m. on Sept. 6, stating that a suspicious object was discovered by Brooks on Sept. 2, which was observed by Wendell, and found to be a comet. Its place was Sept. 3, 16h. 9m. 24·5s. G.M.T., R.A. 16h. 35m. 15·6s.; N. Dec. 64° 49' 33'. The daily motion is — 36s. and — 12'. The physical appearance is circular, less than 1' diameter, 10th mag., well defined nucleus; no tail. It may be of interest to mention that the words of the message actually sent by the Science Observer Code commenced with "unmerited unmusical Brooks unbaptised unnerved Wendell," &c.

The annual report by Prof. Adams of the work done at Cambridge University Observatory has been published for the information of the members of the Senate. Comet Wells was observed up to May 31, 1882, and altogether 182 comparisons with neighbouring stars were made. Of the Great Comet, 1882 *b*, 306 comparisons were made, and 150 of Comet 1883 *a* (Brooks-Swift). The weather entirely prevented any observation of the transit of Venus. From three places of Comet *a*, 1883, Mr. Graham calculated a parabolic orbit which almost exactly reproduces the middle place; and in correspondence with Dr. Carl Stechert, of Berlin, some good work has been done in connection with the orbit of Schäberle's Comet, 1881 *e*.

The directors of the Ben Nevis Observatory have appointed Mr. R. T. Omond, of Edinburgh University, superintendent of the observatory which is to be built on the summit of the mountain. Two assistants will be appointed shortly, and the three observers will then take up their station and prepare to enter on the work of the coming winter. The highest section of the path to the summit is finished, and the building of the permanent observatory has been commenced, horses being employed to carry up the materials. During the winter the work will consist mostly of eye observations, the object being to collect information regarding the climate of the Ben, with the view of deciding what automatic and other instruments will be required for making the various observations in the permanent buildings. Mr. Buchan has been asked to visit the more important meteorological observatories on the Continent, especially those at high levels, and report on the instruments in use to the directors, so that by next summer the Ben Nevis Observatory may be fully and adequately equipped.

The next meeting of the American Association for the Advancement of Science will be held early in September at Philadelphia. The president elect is Dr. J. P. Leslie, of Philadelphia.

M. Hutinet, with Prof. Stebbing, has been visiting many of the principal cities and towns to enable photographers to judge of his simple method of enlarging, and of the value of his improved gelatino-bromide paper, which is said to be so prepared that every sheet can be relied upon to be exactly like any other. The lantern used is a simple square metallic body, with double bent and screened chimney, and an ordinary argand gas-burner. A silvered reflector is connected to the back, and in front of the flame is a sheet of ground glass separating the lantern from the camera. The latter is of simple construction, but is provided with a slot, through which to pass the negative immediately in front of the glass plate. A sheet of cardboard placed in front of the objective (a few feet), serves to show when the picture is sharp and clear, and also as a support for the prepared paper. According to the rapidity of the lens used the exposure is from one to five minutes; but with any ordinarily good carte lens, a minute and a half is sufficient. Ferrous-oxalate is used for development. The process has given satisfaction wherever shown, and, whatever professionals may do with it, will be welcomed by amateurs. The gelatino-bromide paper is patented in all countries.

Last Monday Messrs. Gilbert, Bogle, and Co., of Glasgow, tried one of their electric launches on the Clyde at Kilcreggan. It was driven by Clark's patent battery and motor, Mr. Clark managing the machinery and also steering the boat. The only other persons on board were Mr. Bogle and Major MacIver, for whose inspection the trip was made. Major Maclivcr, who had with him a 15ft. launch, built by Powell and Douglas, of Waukegan, Illinois, has ordered it to be fitted with Clark's machinery. If the experiment be successful, Messrs. Bogle are to construct a much larger vessel for him, to make the trip from the North Sea to the Black Sea, through the Rhine and Danube and their artificial junction. The large boat will be designed for a speed of ten miles an hour, and it will take several months to construct her, but the smaller one will probably be seen on the Thames before the end of October. Major Maclivcr believes that he can make the trip from sea to sea in about three weeks.

---

* Extracted from an article in the *Photographic News*.

The autumn meeting of the Iron and Steel Institute, like the annual meeting of the British Association, commences next week, the former being held at Middlesbrough, commencing on the 18th, the latter at Southport, on the 19th. Amongst the important papers to be read at the former will be those on the manufacture of coke on the Simon-Carvès system by Mr. R. Dixon, and on the Jameson system by Mr. J. Jameson; Mr. I. L. Bell's on the "Use of Raw Coal in the Blast Furnace," and Mr. Smith-Casson's on "Recent Results with Gas Puddling Furnaces." The excursions and visits are, however, the chief attractions of the meeting.

M. B. Renault brought before the Académie des Sciences on the 20th of August "A Contribution to the History of the Formation of Coal." He concludes that coal is, in many cases, produced by the transformation of the constituent elements of the plants the forms of which are preserved, and that both wood and bark have entered into the formation of coal, condensed in proportion to the primitive density of the carbon element.

M. Chevreul, the famous French chemist, entered his ninety-eighth year the other day. He was born August 31, 1786.

A Mr. Watkins, a Clerkenwell manufacturer, has, according to the *Times*, invented a motor for the sewing machine. It consists of a "length of steel tape," which as it is wound up forms itself into a "parabolic spiral," and thus dispenses with the compensating arrangement of the fusee. According to our contemporary, the "tape" is wound up by a winch handle, a few turns of which will store up sufficient energy for an hour's work or more! The action is completely under control; the needle attains a rate of between 900 and 1,000 stitches a minute, or can be made "to work so slowly that the machine scarcely moves."

The "first consignment" of burning-oil from the petroleum wells of Batoum has been landed in Birkenhead.

According to the latest accounts of M. Marcel Deprez's experiments at Grenoble, the results of the attempts to transmit power over a distance of nearly nine miles by means of conductors of silicium bronze show a return of only 15 per cent.

The Rev. L. L. Langstroth, at a meeting of the Montgomery Co. (Ohio) Horticultural Society, recommended the cultivation of golden rod and wild asters on waste land, as bees will forsake almost any plant if they can find either within distance.

Rules for Reckoning Postage. Mr. C. L. Dodgson of Christ Church, Oxford, gives the following rules: Book Post. Find the number of ounces. Take the first even number not less than this and halve it. This gives the cost in halfpence. Letter Post. A letter not over 1oz. costs 1d. Otherwise use last rule and add 1d. Parcel Post.—Find the number of pounds and add one. Take the first even number not less than this and halve it. This gives the cost in threepenny-pieces. N.B. A book must not be over 5lb. nor a parcel over 7lb. A letter over 12oz. is charged 1d. an ounce, beginning with the first ounce. Examples for a book of 5½oz., say "5½, 6, 3 halfpence." For a letter of 5½oz., say "5½, 6, 3 halfpence, and a penny makes 2½d." For a parcel of 5½lb., say "5½, 6½, 8, 4 threepenny-pieces make 1s."

ADAMANTONITE is the local name of a mineral which is said to be found in only one place in the world, and that in the State of Missouri. The *Scientific American* says the stone is very peculiar in its structure and properties. Its cutting power is diamond like, cutting away steel very rapidly, and still retaining an exceedingly fine edge.

LETTERS TO THE EDITOR.

◆◆◆

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, 31, *Tavistock-street, Covent-garden, W.C.*

All Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

⁂ *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original."
—*Montaigne's Essays.*

THOUGHT READING — ATTACHING FOSSILS TO CARDBOARD—POSITIVE RELIEF INSTEAD OF "NEGATIVE" WASTE OF MONEY—LOW BAROMETER—THE LATE MR. C. F. VARLEY —OBSERVING STARS IN DAYLIGHT —SYMBOLS FOR FEET AND INCHES —THE MANUFACTURE OF OBJECT-GLASSES—NOT KNOWING WHERE TO STOP—THE DETERIORATION OF PRINTING—SHADOW OR MIRAGE?—MICROSCOPIC—THE "ENGLISH MECHANIC" AND TIME — CHINESE WHITE—LEVELLING.

[21795.]—HOLDING, as I do, a very definite opinion indeed, myself, as to the (so-called) "transfer of thought" or "thought-reading," I will yet, for the sake of argument, admit it to be a real and objective phenomenon. Having made such admission though, I rather fail to see the difficulty started by "F. W. H." in letter 21747 (Vol. XXXVII., p. 602); because if we conceive thought to consist in, say, molecular vibrations of the brain, it seems more likely that such vibrations should set up corresponding ones in a similarly constituted piece of organic mechanism than that an immaterial entity (if I may employ such a form of expression) should go outside of the only apparatus through, which we have, or can have, any cognisance of its actions—and moreover, in fact, it can conceivably act at all—to impress another similar entity. If a man will sound a chord upon a musical instrument, stopped tubes or stretched strings in the room will each take up its own special rate of vibration, and reproduce it in the form of a specific note; but the performer might *think* of a tune until doomsday without producing the faintest effect in the shape of musical sound on any resonant body whatever. If "thought-reading" be not mere trickery performed by persons either deceiving or self-deceived, it seems to me that it must have its origin in material action. I do not see any necessity for importing the vagaries of theologians into the discussion at all.

"R. R. R." (query 51526, Vol. XXXVII., p. 610) will find that very thick gum-water will fasten fossil shells to cards capitally. I have also glued pretty large fossils (such, for example, as the Euomphalus) on to pieces of board.

"The Government," says Reuter's telegram dated from Simla, "has decided to start famine relief works in the northern provinces, owing to the drought prevailing there." Surely this is a much more legitimate expenditure of public funds than the sending out of any person or persons to take negatives of sunspots: to be forwarded home that some charlatan or other may, by "reducing and discussing them," pretend to predict the advent of famine seasons in the Indian Peninsula.

At 1 p.m. on Sunday, the 2nd inst., during the very heavy gale which then blew, the barometer in my hall (unreduced) stood at 28·683in. I can find no record of a lower reading in my register.

The late Mr. C. F. Varley, whose death is announced in your "Scientific News" on p. 11, presented one of those psychological puzzles which serve to illustrate the truth of the well-known words, "Great wit to madness nearly is allied." A man of great intellectual capacity and high scientific attainments, he was yet the credulous dupe of those most shallow and impudent of all impostors, the Spiritualist "Media." Anyone who may wish to see to what a depth of fatuity a man of great ability may descend, need only turn to p. 62 of your XIXth Volume, and read the account of the elaborate way in which Mr. Varley tried how not to find out Miss Cook's method of performing her barefaced and impudent tricks. The manner in which her paltry deception was at once detected by common-sense investigators may be read in Vol. XXX., p. 502.

In connection with letter 21768 (p. 12), I may just remark that it is by no means necessary to employ an 11½in. reflector to see stars in the daytime. I constantly get the time in sunlight from stars of the 1st and 2nd magnitudes in a 2¾in. transit instrument. I merely mention this to encourage in an interesting kind of observation those who might be deterred by the supposition that it could only be pursued with such large telescopes as that of Mr. Franks.

While heartily endorsing the well-timed protest made by Mr. Hopkins (in letter 21782, p. 15), against the misuse of the symbols ′ and ″. I am not sure that his suggested method of indicating feet and inches would be advantageous. That °, ′, and ″ should be employed in their original signification of degree, minutes, and seconds of arc *alone*, everyone having the smallest regard for scientific accuracy must admit. As it is, we constantly find architectural and mechanical draughtsmen using ′ and ″ for feet and inches; and what is, if possible, worse, I have known an astronomer (?) to write ′ and ″ for minutes and seconds of time! The confusion which might thus be made between, say, 42m. 36·8s. and 42′ 36·8″ Longitude East, need merely be mentioned to be obvious. Having said which, it only remains to add that my chief objection to Mr. Hopkins's suggested symbols is that both π and δ have already very definite significations attached to them, π standing for the number 3·14159265, &c., and δ for Declination. I do not see why people cannot write ft. for feet and in. for inches. These unmistakeable marks of quantity are very nearly as easily written as ′ and ″ themselves.

What "Bow" quotes (in letter 21784, p. 16) from "an old book," is, I believe, still substantially true as far as the objectives of a very large proportion of pocket telescopes are concerned. Lenses, I have been told, are ground in Paris in hundreds of thousands, and are fitted together in the way described.

Apropos of "Bow's" antepenultimate paragraph, I agree with him thoroughly about the punctuation in Vol. IV. of the "Turning and Mechanical Manipulation." A good deal of it induces a reminiscence of the story of the gentleman who, volunteering to read the Lessons in church, rather astonished the congregation by proclaiming that "The wicked flee, when no man pursueth but the righteous, is as bold as a lion": thus seemingly attributing an amount of bravery to a noxious insect with which it has previously not been credited.

I have little doubt that "A Practical Printer" (letter 21791, p. 17) is right in his conjecture as to the cause of the typographic difference between the two works to which I referred. The "Short History of the English People" is printed upon much thinner and poorer paper than the first edition of "The Ipswich Lectures." I find, too, in comparing Herschel's "Astronomy" (in Lardner's Cyclopædia) with Proctor's "Moon," as requested by your correspondent, that the latter work certainly does not show any falling off; albeit the edition of the "Outlines" (Sir J. H.'s expansion of his original work in Lardner), published in 1875, is decidedly worse printed, on the whole, than that was. I suspect that the "Outlines" must be printed from stereotyped plates too.

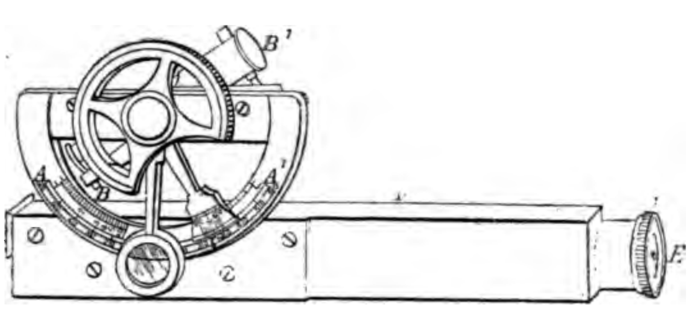
I do not understand the *inversion* of the second shadow referred to by Mr. Ratcliffe, in letter 21792 (p. 17); but the oblique reflection of the sun's rays from the surface of the water would obviously suffice to cast a second shadow in the position indicated.

Reading query 51564 (p. 22), one is curious to know how "L. B. B." determined the value of the divisions in his eyepiece micrometer.

"Salvo Jure" (query 51595, p. 23,) will find that a very little glycerine will keep Chinese white moist and workable. I fancy that Chinese white is zinc oxide.

From a rough calculation, made in connection with query 51574 (p. 22), I find that Vol. CXXXV. will be the first one of the ENGLISH MECHANIC that will terminate in June. Number one of it will be published on Friday, January 5th, 1933, and its twenty-sixth number on Friday, the 29th of the subsequent month of June.

"E. E. R. T." (query 51611, p. 23), will find a dumpy level, such as Elliotts manufacture, the best for rough work abroad. Abney's level, of which I subjoin a drawing, is a very ingenious form of reflecting instrument, which is carried in the pocket, and held in the hand for use. It consists mainly of a tube, T, furnished with an eyehole at E. In the top of this tube is an opening, and within the tube, and half filling it, is a mirror inclined at an angle of 45°. A bubble tube, B B′, set hollow, so that the light can shine through it, has its bubble reflected down into the mirror, when the vernier, V, marks 0° 0′ on the arc, A A′, and the tube is horizontal. If, then, we look through the eyehole, and find any object under these circumstances coincident with the bubble image, such object must be on a level with the observer's eye. Pretty evidently, too, if we direct the tube to any



object above or below the level of the eye, and move the vernier until the reflected image of the bubble comes into coincidence with the object we are looking at, its angle of elevation or depression may be read off by inspection on the arc. I suppose that a builder's level is one of the bubble tubes mounted in a long mahogany box, with a brass bottom, that one sees; unless, indeed, it be the square, with a plumb line, used by bricklayers. Your correspondent should get that excellent eighteenpenny-worth, No. 170 of Weale's Series, published by Crosby Lockwood and Co., London.

A Fellow of the Royal Astronomical Society.

ASTRONOMICAL—δ EQUULEI.

[21796.]—The faint pair of stars in the field with β Cephei, alluded to by Mr. Holmes (letter 21731, page 578), was first mentioned by Σ, but has never been catalogued or measured. I saw it easily some years ago with the 3¼in. Sheepshanks refractor, power 64, the observations being made within four miles of Charing-cross. There is a minute pair mentioned by Webb (Σ 541 *rej.*) between $\kappa^1 \kappa^2$ Tauri, which I have just seen with a power of 64 on this aperture; with 150 it is an easy object. Σ estimates the mag. at 9·10: De, who speaks of it as being extremely difficult with 7¼in., at 11·2, 11·6; but these last are considerably underrated. By "640" Cygni, I presume Mr. Holmes means Ħh 640 (Ħ.N. 110 = So. 726): the decl. of which is 11′ too large in Webb. The minute pairs near this, χ Cygni, and δ Cephei, do not appear in any catalogue; the number of faint Galactic pairs is well nigh innumerable. Mr. Holmes should give the estimated magnitudes, pos. angles, and distances of any new pairs he may chance to find, as well as the approximate differences of R.A. and δ referred to some known star; but faint coarse pairs are not worth cataloguing.

It may interest some of your readers to know that Mr. Burnham has lately made an observation of that wonderful binary, δ Equulei, by which he has been able to determine approximately the period. Hitherto all the observations have been made about the opposite extremities of the orbit, and the stars are so nearly equal in a telescope of 15in. aperture, that it has been impossible, as the motion has seemed so nearly rectilinear, to decide whether the time of revolution was 13-14 years, or only half that number. Mr. Burnham, however, has just shown me a rough diagram of this object, which has served, with the aid of his latest measure, to determine the direction and rate of the motion. The period is about 13 years, and the present distance of the two components is, he tells me, certainly not over 0·25″. This is the most rapid binary known up to the present time, the next being 42 Comæ (Σ 1728), with a period (according to Dubiago) of 25¾ years. The following observations of δ Equulei, by Profs. Winlock and Peters, seem to have escaped notice:—

195·57°: (0·44″): 1869·745 (6 nights).

The measures were made with the 15in. refractor at Harvard, powers 633 to 2004, the stars being just separated on one occasion with 1243. With the exception of this observation and two somewhat doubtful ones of Dunér's this most difficult object seems only to have been seen at Pulkova, Madison, and Chicago. Perhaps the Rev. J. J. M. Perry, who I trust has not altogether abandoned double-star observation, will see what he can do with this? β Delphini is still very close, the distance being only 0·25″, or perhaps even less; it is evidently a binary of short period, probably under 30 years.

September 8. **H. S.**

[21797.]—I am honoured by the notice of the Rev. T. W. Webb. Allow me to explain that "β Cephei × 500" was intended to express as seen with a power of 500, the power being obtained with a ¼in. Steinheil solid eyepiece and a Barlow lens on a 9in. mirror of 75in. focus. The faint pair were in the field with this power.

There is a very interesting group near 31 Ħ in Cassiopeia. When 31 is in field of low power, a triangle of stars is following in same field. Due north of triangle is a patch which a power of 90 or 100 shows nicely. It consists of from 10 to 11 mag. in a straight line, and three rather brighter following at a small angle to the line of the first. The four are about equally distant, and I estimate about 3″ to 4″ apart. The preceding star of the four is a close double—the companion preceding—and the following star of the four is also a double, a little wider and fainter, with the companion following. I estimate these two little companions as of the 13th and 14th mag., but the night was not clear. It appears to me there would be a great deal of difficulty in doing any useful work in the direction indicated by the Rev. T. W. Webb in London, from the great variations of the atmosphere. Not only does this differ from hour to hour, but even at the same hour with an apparently clear sky: stars in one direction will be tolerably sharp, and in another fuzzy. Last night, for instance, ζ Herculis was pretty sharp and good, but at same time doubling the 7·5 mag. of 101 Cassiopeiæ was quite a feat. The faint companion to 60 Cygni was obvious, while β Cygni was two nebulous patches; and the night before, when 429 Cygni was beautifully clear 2624 was very doubtfully double. How to allow for this inequality of air is a puzzle to me.

I should be glad to know what I may regard as the smallest star visible with a 9in. mirror. Of course, a considerable discount must be allowed for London air, for I am satisfied that 6in. a few miles away will show as much as 8in. in London, and show it much more pleasantly. In fact, I think 6in. is about as large an aperture as is useful in London. **Edwin Holmes.**

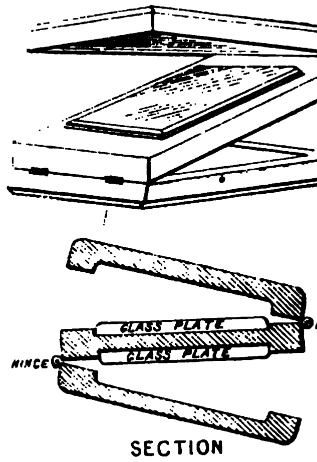
DAYLIGHT PLANETARY OBSERVATIONS.

[21798.]—This morning being remarkably clear, I determined to utilise the opportunity of doing a little telescopic work. Having opened the observatory shutters soon after 7 o'clock, I picked up *Saturn* by 7.15, two hours after sunrise. The planet was pale, but very beautiful, bearing a power of 160. The shadow of ball on ring, principal division in ring, and the dusky ring where it crossed the ball, were well seen. The ring has opened perceptibly since last season, and now extends just beyond the ball. The greater yellowness of the ball as compared with the ring was obvious enough. *Mars* at 7.25, very bright, and its orange tint conspicuous; it bore a power of 300 well. The gibbosity on *p.* limb very plain, the N. pole cap and some dusky markings seen, but its diameter of 7″ not enough to identify them. This is certainly the next planet to Venus for brilliancy in sunlight. *Jupiter* at 7.35, a little pale, but looked noble with 160; all the belts well seen, the S. equatorial one especially strong. The colour of the planet was white, with a faint tinge of yellow, very similar to that of Venus, only, of course, incomparably paler. The vivid blueness of the sky background might possibly affect the whiteness of an object in daylight, giving its complementary tint of yellow to it. *Venus* at 9.5 a.m., well defined and excessively bright, now only 11 days from superior conjunction. I have used two methods of reducing the distressing glare of light in the sun's vicinity. One is to employ a light neutral-tint moon cap with full aperture; the other is to use a very small eccentric stop (I have a revolving diaphragm for solar observation, with various apertures from 2¼in. to 4½in., which answers capitally). The latter plan is preferable, giving steadier definition. Powers of 160 and 240 were used, and, in extra steady moments, I suspected some departure from uniform illumination, but nothing definite enough to sketch. *Mercury* at 1.25 p.m., about dichotomised, but perhaps slightly concave; terminator very irregular. It would not well bear a high power, being very fluttering, and only occasionally steady. The colour of this object, carefully noticed with various eyepieces (and on the 4th and 8th inst., as well as the present occasion) was decidedly a dull yellow. In 1877 I had noted it, as seen with 5in. o.g., pale white in the daytime. But I am disposed to give more weight to the present observations, made with an instrument of four times the light-grasping power, and free from the disturbing effect of chromatic aberration. It is seldom one gets such an opportunity of comparing together all the five planets of the ancients in the broad light of day. In relative brightness the sequence was:—Venus, Mars, Jupiter, Mercury, Saturn—though in the case of Jupiter and Mercury the order might be reversed if Jupiter was *south* and Mercury *north* of the sun. In the *Nautical Almanac* the ephemeris of Jupiter, "at transit at Greenwich," only begins on Sept. 22nd, for the present season—whereas it was plainly visible a month earlier, as it passed the meridian here, with my 11¼in. telescope. I may add that Castor was seen this morning at 8.20, marvellously wide, like two points; and the difference of magnitudes was apparently greater than at night, at least 0·7m.

Sept. 9th, 1883. **W. S. Franks.**

HANDY SURFACE PLATE BLOCK.

[21799.]—I beg to call the attention of amateurs to the useful surface plate sketched below. It is made as follows:—A piece of plate glass, ¼in. thick by 12in. by 4in. is procured at a glass warehouse, and divided into three pieces, making each about 4in. square. One side of each piece is then surfaced on each other with a little fine emery and oil, thus: No. 1, for sake of clearness, is rubbed in little circular motions on No. 2; then No. 2 is taken to rub on No. 3; No. 3 on No. 1, and so on, ringing the changes on the three till either lies perfectly flat on its neighbour. Mount two of the best plates in a suitable case with plaster of Paris, of course bevelling and grinding the edges of the glass on a sandstone with water, to give a finished appearance to the job. The remaining plate can be kept by for rough surfacing, or to take the place of one of the two in the case should either happen to get broken.



SECTION

HANDY SURFACING BLOCK AND CASE

I often use an arrangement substantially the same as this for sharpening my slide-rest tools and cutters, also any small surfacing I have to do, and have no reason to do away with an old friend for one of Whitworth's, or any similar make. I should like our friend "A., Liverpool," to try surfacing small work on the above little affair, and also on a piece of wood, no matter how nicely it is planed up, and kindly give us the benefit of his experience, as I notice on page 582, he recommends the latter plan, and also scraping. The scraper, when properly used, is, I admit, very good for bringing up large work to surface; but when you have an awkward little piece that you can scarcely hold in your fingers to surface, the best way is to work it up on the plate. When using this surfacing-block one side should be used with fine emery and oil to bring the work up to a face, and the other side used with clean oil only to finish the work off smooth. This is my way of surfacing slide-valves, port faces, and any small part requiring an absolutely flat surface.

It is not necessary that this surfacing block should be mounted as shown. Any other way would answer just as well, provided the glass is not subject to undue strain in the mounting. I simply send this as an arrangement which I think would answer most purposes of the amateur engineer.

A. Austel.

BERTHELOT ON EXPLOSIVES—STAR CATALOGUES.

[21800.]—In No. IV. of the admirable series of articles on "Explosives," page 10, the subject of "Explosion by Influence" is treated upon. Allow me to mention a case which did not follow the usual rule. On the 29th ult., I accompanied a friend to destroy a cartridge of Nobel's gelatinised nitro-glycerine. The cartridge was placed on the grass, and in close contact with it a "primer" of the same material, in which the usual fulminating detonator was firmly pressed, and a piece of fuse attached. The detonator exploded the primer all right, but not the main cartridge. The latter simply ignited, and burnt away with great fierceness. It might be supposed that the detonator was too weak, but this could scarcely be the case, for we had previously exploded two, three, and four cartridges together with detonators from the same packet, taking no precaution to tie the cartridges, but simply laying them side by side. In this instance, however, I did place a stone on each side, to prevent the cartridges from rolling apart. On examining the spot directly afterwards, it appeared, from the burnt grass, as if the main cartridge had been blown aside by the initial explosion and ignited, instead of exploding as we expected. Can any brother reader who has had a larger experience throw any light on the matter?

With respect to Mr. Holmes's remarks on "Star Catalogues" (21451, p. [illegible]), I should think that Proctor's "Handbook of the Stars" would be the most useful to "R. K. P.," and certainly there is nothing cheaper. The "B. A. C." is a splendid catalogue, containing 8,377 stars, down to 7 mag. generally, although a few lower ones are included; yet there are a goodly number of naked-eye stars not mentioned in it, to my knowledge. The places of stars, however, are given with great precision, and also the constants for reduction; the epoch is 1850. But its great drawback is the extremely loose manner in which the [illegible] are expressed; these are utterly untrustworthy. Added to which the catalogue is out of print, very scarce, and commands a high price. The "Catalogue" of Heis, accompanying his "Atlas Cœlestis," would be preferable, inasmuch as its author is our greatest authority on the subject of magnitudes. It contains 5,422 stars, arranged in constellations, for epoch 1855. But the places are only given to nearest minute of arc, both in decl. and R.A., and there are no precessional constants. Moreover the expression of R.A. in ° and ′, instead of in time, is highly inconvenient. Some copies of this work have two pages of corrigenda; but, besides these, a very long list was published by Professor Peirce, "Annals of Harvard College Observatory," Vol. IX. Personally, I prefer the Greenwich Catalogues for star places, and these volumes may often be bought at a secondhand bookseller's, whilst I trust to Heis and Argelander for magnitudes. I know of no one catalogue that fulfils all the desired conditions, or I should have obtained it long ago. There is just one statement by Mr. Holmes, if he will pardon my mentioning it, where he says — "The drawback is that there are *hundreds* of stars not visible to the naked eye not included in the maps." The italics are mine. This refers to the large atlas of Proctor, if I mistake not the preceding sentence. There may be some [illegible] of such stars (and I have come across not a few myself), but [illegible] is "too much" even for my indulgent belief! If Mr. H. will excuse me, I think that his labour would be better expended upon the conversion of his alt-azimuth stand into an equatorial one, and then he would require no such elaborate maps. May I tell him, though strictly *sub rosa*, that I have heard a whisper of a new "Star Atlas," that is to eclipse all predecessors, being in course of preparation!

September 7th. **W. S. Franks.**

SQUARE NUMBERS.

(Continued from No. 961, [illegible].)

[21801.]—The squares of the natural numbers 1, 2, 3, 4, . . ., are worthy of consideration. The series 1^2, 2^2, 3^2, 4^2, 5^2, . . . includes all integral squares. Taking the differences of the squares in the order in which they stand, we get the series of odd numbers 1, 3, 5, 7, . . ., from which we see at a glance that every odd number is the difference of two squares. Hence every odd square is the difference of two squares. 25, for example, is the difference of the squares 144 and 169, which are found by adding and subtracting one from the given square and dividing by two, thus 26 ÷ 2 and 24 ÷ 2 give 13 and 12, then we get $13^2 - 12^2 = 5^2$. Also two squares whose difference is 81, will be $(82 \div 2)^2$ and $(80 \div 2)^2$ or $41^2 - 40^2 = 81 = 9^2$.

Taking the differences of the ultimate terms of the series, we get the series 8, 12, 16, . . ., which are all multiples of 4; it follows that every multiple of 4 is the difference of two squares. To find the squares for any given difference, divide by 4, then add and subtract 1 for the roots. Thus 12 ÷ 4 = 3, adding 1 and subtracting 1, we get the roots 2 and 4, whence $4^2 - 2^2 = 12$. If the difference is 100, then 100 ÷ 4 = 25, from which we get $26^2 - 24^2 = 100$. We may state here that the geometric series, 1, 2, 4, 8, 16, . . ., if every term is multiplied *by the sum of two squares, each of them will also be the sum of two squares, and every term after the second being a multiple of 4, will also be the difference of two squares.* Multiplying the series by 10, which is the sum of two squares, it becomes [illegible]. [illegible] Now [illegible] = 14 − [illegible], the sum of two squares and [illegible] = [illegible] − [illegible], the difference of two squares, from which we deduce [illegible] = [illegible] − [illegible].

The odd number [illegible] is the difference of 2 squares, and [illegible] it is easy to see that [illegible] = [illegible]. From these equations we get [illegible]. From this, treated in the same way, we find a square the sum of [illegible] squares, namely [illegible]. Again—

[illegible]

L. S.

ARCTIC COLD.

[illegible]—Having been unable before to answer Mr. Lancaster (letter [illegible]), I trust you will allow me a few lines in reply to same. Mr. Lancaster says, "the whole question seems to me to be most easily solved when we consider what does really take place." And that is just what we ought to consider, for I think the problem is not solved yet. For instance, why do not those enormous sudden changes occur more regularly, oftener, or periodically? Because an ordinary Polar current would not change the temperature to such a great extent and in such a short space of time, especially from 54° down to 10° or 12° Fahr., or even lower. That I will prove presently, and anybody who has spent some time in the far North will agree with me. Here I will give a few facts. First. Why does not the Pole, or rather why do not the Polar currents, issue the same amount of cold each winter? Someone would answer, "The wind has been south." No, that is not the case; for it is known that the wind has been blowing from the north for weeks, and still the cold has been very moderate (that is experienced in Norway, in the north of Sweden and Russia, and even Spitzbergen and other north-lying places can have very moderate cold some years. Secondly. Why do not the Polar currents issue the same amount of cold for each mile, or ten miles, they traverse? Because the nearer they arrive towards the south the more cold they lose? No, that is not the case, one place lying 10 or 40 miles more south than another may have 10° or 15° more cold than a place lying so many miles more north, although at both places the wind has been full north. Thirdly. Does Mr. Lancaster believe that he can get ice an inch and a half thick in 12 hours, in a temperature of 30° Fahr.? No, that is simply impossible, at least in the north of Sweden, the 5th of October, and anywhere else, where temperature has never been lower than 54° for the previous six months. The temperature (as far as I can recollect) was at 7 a.m. 8° Fahr., but it may have been still lower. Fourthly. The same amount of cold which came on so suddenly at the beginning of October, should certainly have lowered the quicksilver to 4° Fahr., or perhaps 2° Fahr., if it had been in January instead of October. That may seem strange; but that is the case, and I will explain it presently, if somebody should not know, or perhaps have never thought of it. Still, we cannot so easily detect it in England as one may do in the more north-lying countries. We know that the earth absorbs a great deal of solar heat during the summer. Now, Mr. Lancaster says, heat radiated from the earth is retarded or absorbed by a moist atmosphere, and is not absorbed by a (perfectly) dry atmosphere. This, of course, is impossible to find in nature.

Does Mr. Lancaster mean that we cannot see the radiation of the heat from the earth? If so, I will prove that he is not correct. After a warm summer day, a cool night may set in; the cool atmosphere is rushing down toward the hot surface of the earth, and, coming in contact with the earth, the cool air is condensed into steam, which gradually settles down on the ground in drops—what we call dewdrops. Or, as is more plainly seen in the North in the autumn, especially if the night is very cool, or the cool season sets in very suddenly. In the morning the rivers or lakes look full of steam, caused by the cooler atmosphere coming in contact with the much warmer water. So an ordinary Polar current (excuse me for using the word "ordinary") could not possibly produce such an enormous change in the atmosphere in such a short time as 12 hours. It must be, at certain times, some kind of revolutions in the Polar regions, or, at least, in the Polar currents, which bring such a great quantity of cold to one single spot, say, within a radius of from 300 to 800 or 900 miles or more. Therefore such a great change would be, I should think, impossible, at the beginning of October, with our ordinary Polar currents, and that for the simple reason that, at such an early date, the earth still possesses so great an amount of heat that the radiation of such heat would take longer than 12 hours to absorb and equalise the temperature of the atmosphere and the earth. Mark me, I have spoken about the plains of Northern Europe, and not the Alps. Anybody who has experience of cold climates where the quicksilver has been frozen hard as a stone in the morning, and in the evening the thermometer has shown over 50°, will agree with me that the vast difference between two such extremities is still something for our learned professors to explain.

Hot and Cold.

FREE REEDS.

[21803.]—As I wish to supplement the remarks on p. 14 of our new volume, I should like to draw the attention of Mr. Child to the wonderful effect produced by the application of what are known as the patent qualifying tubes, which are used in the reed organs manufactured by the Clough and Warren Organ Company of America. These tubes, which are constructed of wood, have the effect of increasing the volume, power, and quality of tone from the sets of reeds to which they are applied. This, at least, is one experiment which has been tried, and proved successful. This fact also proves that the tubes can be made to influence the quality of tone, if at present the tubes do not influence the tone, the reason of which is because (as I remarked before) they are made to one scale throughout the organ. As such is the case, how can the tubes be expected to have any influence on the tone? The popular or general idea is that the tubes are of little or no consequence—that is, with regard to their influence on the tone; and as I have practically proved this idea to be erroneous, I must differ.

G. Fryer.

[21804.]—I do not know what is meant by the phrase, "eventually contradict" (p. 14); and certainly my letter on p. 603 was not intended to contradict the statements of Mr. Fryer, for that would be a work of supererogation. It is quite true that Mr. Fryer said on p. 580 he had "proved by practical experiment that characteristic tone can be obtained without voicing the reeds"; but he considered the experiment evidently so great a discovery—as, indeed, it is—that he forgot to tell your readers how he arrived at it. I can promise your correspondent that if he will only explain definitely "how it's done" he will have one attentive reader; but he must really let a little more light into the matter than he does on p. 14. Mr. Fryer's first statement was that the size and position of the tubes necessitated voicing; now he says that, according to his experiments, "voicing the reeds is not in the least required or in any way necessary." It is very kind of Mr. Fryer to state that he has "nothing to say against voicing the reeds, only that it is an art in which very few excel"; and very noble of him to confess that, although he can voice reeds to a certain extent, he can rarely or ever do it to his own satisfaction. But Mr. Fryer has misunderstood my remark that he imagined the shape and position of the tubes necessitated voicing; for, of course, if he spoke from experience, how could I know anything about it when I only spoke from a knowledge of what has been done in the trade since the American organ was born, and had (unfortunately, still have) no knowledge of the wonderful discovery of Mr. Fryer? That gentleman objects to my citing the orchestral organ as a proof that the shape and position of the tubes do not necessitate voicing, but that voicing (in the American fashion) is purely supplementary; and he objects on the ground that it is really a harmonium, whereas his remarks apply only to instruments constructed on the suction principle. Just pausing to note that the only difference of importance is the difference in the pressure of the wind, I may point out that I selected the orchestral organ for this reason: that its European cousin is made by one of the most accomplished reed organ builders in the world, who has done all that can be done for it in the matter of shape and position of tubes or channels, and has made it the first harmonium *par excellence*. Now the Americans have taken that instrument, and by their system of voicing have improved it; hence, as I said before, voicing the reeds is the primary consideration, the position of the tubes and their size have only a secondary effect, and so I must continue to believe until Mr. Fryer tells us how he manages to get characteristic tone. He is "prepared to say" that he has actually tried the experiment (p. 14), and being "prepared" to do all that, he might go a little further and tell us how he does it. Mr. Fryer "maintains" that when "all the tubes are made to one scale it does not influence the tone." I am not quite clear what the "it" means, or what Mr. Fryer "maintains," and how he does it; but on p. 21 I see he recommends "G Minor" to build his instrument on the suction principle, and get his tube-boards with reeds unvoiced, knowing, presumably, that the three tube-boards which "G Minor" is to get will have "all the tubes made to one scale" in their respective registers, unless he (Mr. Fryer) will tell "G Minor" what size he ought to obtain. I believe the American manufacturers will make the tubes any size, and stick them where you like on the soundboard. I may first mention, as Mr.

Fryer seems in a bit of a fog here, that "row," as applied to a tubeboard, will be understood to mean five octaves, unless some other number is specially mentioned. But what can be meant by the recommendation to get the boards with unvoiced reeds, when it is stated elsewhere that the tubes being all of the same scale will necessitate the voicing of the reeds? Why not state what size they should be to obtain the characteristic tone without voicing? Surely Mr. Fryer is not going to patent his secret? I begin to think that, with Mr. Fryer's aid, a very useful series of maxims for reed organ builders might be put together, which could be hung up in the workshops for their edification and the wonderment of the apprentices. On p. 14, for instance, Mr. Fryer says:—"Voicing the reeds does not affect the mechanical stops in any organ." How would something like this do? My "maxim" is not quite so profound as the other, but it is at least apposite and opposite.

MAXIMS FOR REED ORGAN BUILDERS.

By G. Fryer and N. E. Child.

Voicing the reeds does not affect the mechanical stops in any organ.	The size of the stop-knobs has no effect on the tone of the reeds.

I might add another maxim by Mr. Fryer which I find on p. 584, but I am not prepared just now with another on my side of the "table"; still, I must not deprive anyone of it. Steel reeds cannot be voiced, because, although steel will bend, it will spring back to its former position. That, be it noted, is the deliberate dictum of a man who, although not a reedmaker, has had "some years' experience in all kinds of reeds." I am sure that when the number of the ENGLISH MECHANIC for Sept. 7 reaches the United States there will be a rush for it, which will be followed by an absorbing anxiety to learn how Mr. Fryer obtains characteristic tone without voicing reeds. I hope he will give the information without delay. **N. E. Child.**

TRANSFER OF THOUGHT.

[21805.]—A GOOD deal has been written of late in the columns of this journal on the above subject. Permit me to give the result of some recent personal experience.

I was visiting last week some relations of mine at St. John's-wood, when the conversation turned on thought reading, or the transfer of thought, which is perhaps the better rendering. I had not given the matter any actual attention. I had read the letters which have appeared herein on the matter, as well as the correspondence in the *Times* between Mr. Bishop and Mr. Labouchere, in which I thought the latter had much the best of the argument; but beyond this I knew nothing. It seemed that some friends had been recently visiting at the house, who had given an exhibition of their power of thought reading, the explanation of which was attempted, but, owing possibly to personal density, I did not quite gather what was intended, and as the children of my relations had quite unexpectedly developed similar power, it was proposed to exhibit it for my benefit. I must premise that the family consists of the parents and four girls – Gertie, aged 18; Flossie, 16; Jennie, 12; and Jack (a pet name), 9; all as bright and merry children as ever gladdened a home. The experiments were as follows:—

Flossie was blindfolded and sent out of the room, and when the door was shut, I was asked to indicate something she was to do on her return. I said in a whisper, "Let her take an envelope (which chanced to be lying on the mantelpiece) and give it to me." She was then called in, and without a word being spoken, Gertie and her mother stood on each side of her, with their hands lightly pressed on each shoulder. The child soon made a forward movement down the room, and feeling for the mantelpiece, ran her hand along it till she found the envelope, felt till she found me, and put it into my hand.

The next to be sent out was Jennie, and in the same manner I again proposed that she should select from a pile of coppers *the last penny*, and give it to me. She was brought in as before, the same persons in contact with her, and in perfect silence she felt her way down the table, passing her hand over it till she found the money, then she lifted the whole, and selected *the last penny*, and gave it to me.

The next was Jack. I proposed, as before, that a thimble, with which one of them had been working, should be put into a little box, from which she was to take it and put it on a tray near by. This time, her two sisters, Gertie and Flossie, were sponsors. The child felt her way as the other had done, took up several things on the table, and put them down, till she came to the box, which she opened without hesitation, took out the thimble, put it on each of her fingers in succession, seemingly not satisfied, and finally deposited it on the tray. This was not a little marvellous, because the child could have had no personal consciousness that the thimble was in the box, having been placed there in her absence, and it would have been more in accordance with the ordinary fitness of things had she kept it on her finger. I asked her afterwards why she did not do so, she said "it did not feel right."

The next experiment was very interesting. Flossie was again sent out, and I suggested that she should remove the brooch her mother was wearing, and fasten it on the sleeve of the coat of her father, who was sitting in another part of the room: but we changed this and made that it should be fastened on one of the fronts. This time Gertie and myself were the sponsors, as I call them. The child came in as before, hesitating for some moments before she moved; then felt her way till she found her mother. She first took out her earrings, but at once replaced them and felt for the brooch, which she unfastened; then felt around till she found her father, and here she hesitated some time. She put the brooch in his hand but at once removed it; then on the sleeve of the coat, hesitated again, whispered to herself "it doesn't seem right," and finally pinned it on the coat at the place agreed upon.

Lastly, Jennie again went out, and I proposed to take off my watch and place it in a writing desk which stood on a sideboard, from which she was to remove it and give it to her mother. I and Gertie were sponsors as before. The child came in and, instead of going to the table as usual, felt around the room till she found the desk, which she opened, took out some things in the pen tray, replaced them, hesitated, closed the desk, went away, but came back; and this time she lifted the lid, took out the watch and carried it to her mother as agreed.

I have no explanation to give of these things, and they will probably read less strange than they appeared in the doing. I need scarcely say that collusion is out of the question. It has of late been made a family amusement, and to suppose that they would dupe each other, even if it were possible, would be absurd. I proposed in all cases what should be done when the child was out of the room, and not a word was said after her return. There was something almost uncanny in watching the blindfolded child groping her way in perfect silence and slowly but certainly doing what had been agreed upon. It seemed to me that each, like a pythoness of old, had their own volition suspended to become the impassive medium of a power external to themselves. It is only the three younger children who possess it, the eldest and the mother (the father will have no hand in it) can do nothing, and I was equally unsuccessful. I think the explanation is to be found in what I may call the greater passivity of children; their own wills are more easily put into perfect obeyance, and they follow blindly the prompting of their minds; while with older people an unconscious autagonism seems to be set up, which is fatal to success. It is necessary for the person whose hands are in contact with the medium to think very strongly of the object to be attained, and it is much more exhaustive to them than to the other. As I said before, I have no explanation to offer, but that thought can be transferred in the manner I have indicated is to me an absolute certainty, and I think, had the most sceptical of your readers seen what I did, they would be equally assured.

F. H. Carter.

13, Berkeley Villas, Wood Vale, Forest Hill.

[21806.]—BY some oversight I left out part of my letter 21779, p. 15, so that I now complete the remarks I intended to make on what was said by "F. W. H.," 21747, p 602.

In what I said I carefully left the particular point open on which his difficulty was founded, viz., the question whether there is in man an inner spiritual agent distinct from the material organs. But as Mr. Grey, 21778, p. 15, while speaking directly only as to so-called spiritualistic experiments may leave the impression that the belief in spiritual existence rather implies the want of being "advanced enough to follow the great German scientists," I will say that the very opposite is really the case. For myself I recognise the truth of all they say as long as they remain within the proper limits of *science*, that is of what is to *be known*. But when they pass from science into negative metaphysics, the great German or any other scientists are no better guides than any other people who talk about what they know nothing about.

As long as they follow out the operations of physical organs, and the probable mode of development of those organs and the evolution of the animal beings (including man) to whom the organs belong, they are in their rights, and I will and do go with them; but when they try to limit life and thought to these organs, and deny the existence of anything beyond them, it is they who are not "advanced" enough to comprehend truths too subtle for them.

It is like the presumptuousness of children when the anatomist denies the existence of some higher principle, because he cannot find it when dissecting the organs which alone are at his disposal, while yet he cannot offer the smallest explanation of the living action of those organs by anything his scalpel can reveal. That is *not science*; it can only be classed with other sayings which a writer of old very justly attributed to "the fool." To investigate the operations of nature and fail to see that those operations indicate *thought* and *will*, and that whether in nature as a whole, or in man as a part of nature, these faculties and that of consciousness involve a something inconceivable as belonging to the constantly changing atoms of which the body is constituted, is no sign of "advancement."

It is true that not only do the unquestionable facts exhibited in mesmerism very strongly support the belief entertained by the highest minds of all the ages, in an agent distinct from the bodily organs though operating through them, but the subject of transfer of thought is not necessarily limited to such an agency.

It is perfectly well known that every act of thought involves a physical action of the material brain. Its motions during thought can be felt and have been seen. Thought is accompanied by a development of heat in the brain, as also may be felt, and a concentration of nervous energy there which often makes the rest of the body cold. Now all this means a consumption of matter and a transfer of energy. Whether we hold with the materialist that these actions are themselves the agent, or with the spiritualists that they are the operations of an inner agent, the material facts are the same. It is no more improbable that such actions may *induce* some corresponding motions in another brain, and there develop the same thought, than that a motion of electricity or of magnetism should *induce* a similar motion in other electric or magnetic bodies. No man knows what the nervous agent is, but we well know that, while it is certainly not electricity, it is something having many analogies to electricity; and, therefore, there is an *à priori* probability of similar inductive actions existing.

But, after all, the consideration of what bearing the transfer of thought may have upon materialistic or spiritualistic conceptions of man's existence is absolutely out of place; it ought to have no effect upon any reasonable mind, because the one thing to be asked in this, as in all other cases, is, What is the truth? Does the fact occur? This settled, we may reason from the ascertained fact in any direction; but no supposed consequences ought to enter into this preliminary examination. **Sigma.**

[21807.]—REPLYING to my letter (21666), wherein I deny the possibility of a man seeing without eyes, "Sigma" says that "any intelligent doctor will tell me that we do not see with our eyes at all." In "Sigma's" last communication (21779) he informs us that "if a cataract forms on the eye the man loses sight, though his brain and optic nerve remain perfect." Comment is unnecessary.

T. E. D. Craven.

[21808.]—I ADMIT Mr. W. J. Grey's theory of a material connection being established between two brains in a natural way as perfectly possible, although the "how" may be unknown at present.

I also agree with "Sigma" that a "faith" not founded on scientific or so called "material" evidence, cannot be destroyed by any amount of such evidence. Neither did I desire myself to attack such "faith." All I wished to point out to your readers is that if what is now called soul, mind, or thought in man is merely the resultant of the molecular action of the brain, like "go" in a watch is the resultant of the machinery in motion in such watch, it appears to me impossible to treat "soul" or "go" as a "transferable" entity.

The view now taken by Büchner, Haeckel, and other scientists on production of evidence, the scientific value of which seems to me undoubted, does not question the existence of this "essence," but looks upon it no longer as an "agent" working with "tools," &c., but as the "product" or resultant of "brain" in motion in man.

F. W. H.

P.S.—Moleschott says: "Thought is a motion of matter."

CLARK'S IMPROVED DIAMOND HIVE.

[21809.]—I HAVE taken the *British Bee Journal* for years, and was struck by the likeness of the above-named hive to one that appeared in the *British Bee Journal* under the name of the "Anglo-Cyprian Hive," T. B. Blow, Welwyn, Herts, inventor, May 1st, 1883. In the *B. B. J.* of June 15th, 1883, the following appeared: "Why, friend Blow, somewhere fifteen years ago exactly that beehive was invented and patented in the United States by a well-known bee culturist (Dr. U. S. Conklin, of Ohio). It was called the 'Diamond Hive.'" Under these circumstances, I should like to know who was the original inventor of this mighty "Diamond Hive"? Was it Homer? **Apis Mellifica.**

[21810.]—I BELIEVE this style of hive was first brought out in America in or about 1851, and found unsatisfactory and given up. The same idea has

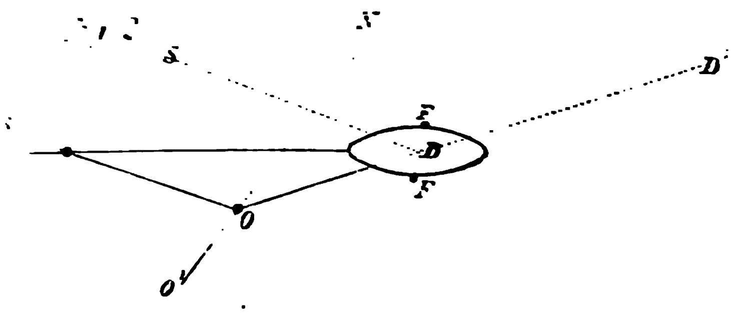
THE THEORY AND CONSTRUCTION OF THE HELIOSTAT.

I.—Geometrical.

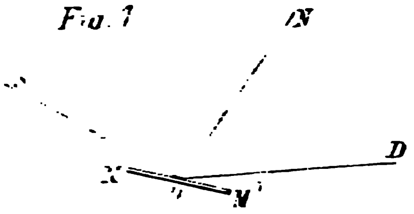
[illegible] heliostat may be defined as an [illegible] which the sun's rays may be re[illegible] [illegible] desired [illegible] direction being [illegible] throughout the time during [illegible] the earth.

[illegible] the several [illegible] by which this has been effected, it will be [illegible] the geometrical problem [illegible].



[illegible] Fig. 1 represent any point on the Earth's [illegible], O N the direction of the North Pole of the [illegible], O S the direction of the Sun, O D the [illegible] which it is desired that the reflected ray [illegible]. Let MM' be a plane mirror. Then the [illegible] condition is that, as the sun's direction [illegible] during the day, the mirror should be con[illegible] moved so that a normal to its surface [illegible] constantly lie in the plane S O D, and bisect the angle S O D. [illegible] that in the general case the motion of the mirror will be a complex one, no single [illegible] motion satisfying the problem: but a particular case may be noted—viz., when the desired direction of the reflected ray coincides with the polar axis of the heavens, or when O D lies on O N. Then, clearly, the motion of every point of the mirror will be a circular one about O N as an axis, and we obtain a solution of the problem for this particular case, by mounting the mirror on a stiff joint at the end of a rod pointing to the pole and causing this rod to revolve once in 24 hours. The mirror having been set in the morning so as to reflect the light in the direction O N, will thus continue to do so throughout the day. A second mirror may be fixed in the path of the reflected

Fig. 1



beam, and may be set to reflect the light further in any desired direction. Thus, with the aid of two mirrors, the problem is at once solved in all its generality, and this is by far the simplest construction. The first heliostat made was on this principle, and was constructed by Fahrenheit. As this construction is simple enough to bring it within the powers of every amateur to construct a serviceable instrument, we shall subsequently give full instructions for making it.

There are, however, manifest disadvantages in using two mirrors, and several solutions have been given by which the requisite complex motion may be imparted to one mirror only. Silbermann, Gambey, s'Gravesande, and others have all proposed solutions, and instruments have been constructed in accordance with them. The one we propose to describe is a slight modification of Gambey's, and is, on the whole, more simple and smoothly-working than the others. The geometrical principle upon which it rests will be understood from Fig. 2.

Let O D be a hollow rod containing within its bore the "handle" of a "fork" O F F' between the prongs F, F, of which the mirror M M' can turn freely on centres, after the fashion of a swing looking glass. Let D S be a rod fixed rigidly to the mirror, and in the plane of the mirror, and capable of sliding freely through a Hooke's joint at S, at the end of O S, a rod which can be clamped to the polar axis O O', and rotating with it so as to describe a cone about it, having its vertex at O. Let the hollow axis O D be fixed in space, and point in the desired direction of the reflected ray. Let O S be brought to point to the Sun, and then clamped to the revolving polar axis. It will be at once seen that the mirror will always reflect the light in the desired direction, provided O S = O D, D being supposed to be midway between the centres on which the mirror turns. The proof is very simple, and we may leave it to the reader, merely remarking that S O D being an isosceles triangle, S O and O D will make equal angles, with a perpendicular from O on S D, and that consequently S O, O D will make equal angles with the normal to the mirror: that is, they will be incident and reflected rays respectively. The fork F F', of course, secures the condition that the mirror should remain at right angles to the plane S O D or S D D.

In subsequent papers we will describe the practical construction of Fahrenheit's, and the modified Gambey's heliostats.

A. T. Hare.

(*To be continued.*)

THE PANAMA CANAL, &c.

[illegible]—So far as I have ever read or heard, the Panama Canal, by whatever route projected, will necessitate the construction of locks; the geographical conditions being, by any possible route, very different from those of the Suez Canal. If this is so, the idea of diverting the Gulf Stream is absurd. J. R. D.

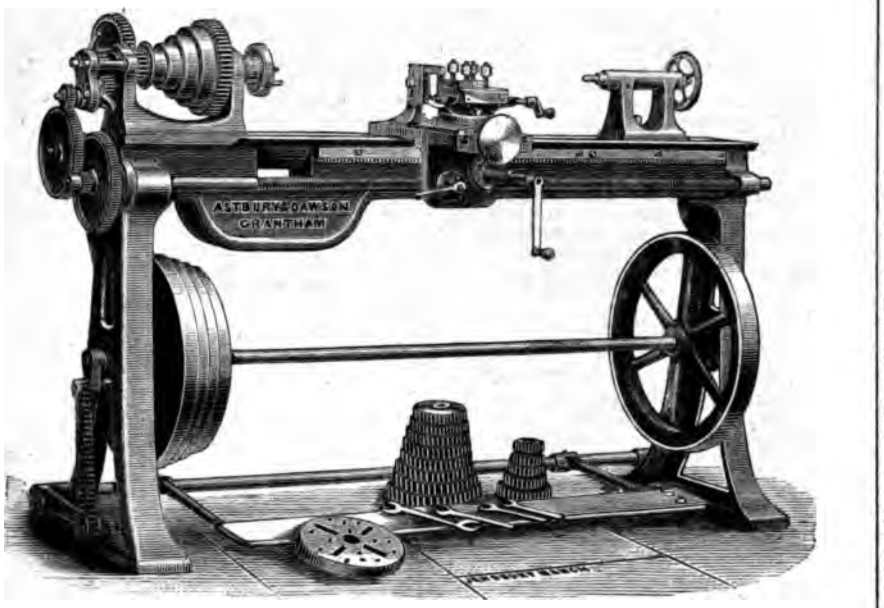
STANDARD 6in. SELF-ACTING FOOT-LATHE.

[21817.]—In your issue of Aug. 3rd, a passing notice appears of our exhibits at the recent Engineering Exhibition at the Agricultural Hall. Thinking that detailed particulars of one of our amateur lathes would interest your readers, we have pleasure in sending herewith an illustration and description of our standard 6in. screwcutting foot-lathe. For a future issue we will send illustrations of our set of amateur turning tools, noticed by "O. J. L."

The illustration represents our Standard 6in. Centre Amateur Foot-Lathe, with sliding and screw-cutting gear. This lathe has a gap bed 6ft. long, admitting 4ft. between the centres, whilst the gap will admit a piece of work up to 22in. diameter. The headstock is double geared, and fitted with conical bushes. These bushes are made of phosphor bronze, a material that gives very good results; steel bushes, however, are fitted when preferred. The bushes are brought to a true bearing for the mandrel, which is made of mild cast steel. The lathe shown has cone speeds for a flat strap, but a grooved cone for gut band is adopted if preferred. The ratio of the wheels and pinions forming the "head gearing," makes the headstock a very powerful one for surfacing, &c., without being heavy; the back gear is thrown out by an excentric. The headstock also carries a reversing motion, with wrought-iron cut pinions. The saddle, which carries a compound slide-rest arranged for surfacing, turning conical, &c., has long guiding surfaces, and is traversed by hand by rack and pinion. The guide screw is accurately cut in a Whitworth lathe to ¼in. pitch. Due attention has been given to the treadle motion, which has a very good action. The shaft revolves upon antifriction rollers, the crank being placed outside the standard as shown; a small antifriction wheel at the opposite end enters a groove in the shaft, effectually preventing endwise movement, with less friction than if a collar were used, and it constitutes a very neat arrangement. All the levers —including the crank—are keyed on with steel taper pins; this makes a good reliable job, set screws being unsatisfactory to a degree. All gearing is cast from machine-cut *iron* patterns, and the various screws, nuts, &c., are uniform sizes, and well fitted, all the *working* nuts are made of *steel* and hardened.

The lathe includes 22 change wheels, back stay, face plate, and a full set of screw keys.

Grantham. **Astbury and Dawson.**



KEY CHARACTERISTICS IN PIANO MUSIC.

[21818.]—Allow me to assure Capt. Cuttle that nothing he has said has so much as ruffled one of my feathers, and that what he has said in his letter on p. 14 does him great credit. The sole remaining difficulty will be easily explained if Capt. Cuttle will remember that in piano-playing—and with that only are we concerned—keys are not "pressed down," but struck; and it is only the "touch" of the performer that makes any difference in the force of the blow or the rapidity with which it is struck. An examination of the action ween the key and the string will show the effect of pressing as compared with striking. I shall be pleased if Capt. Cuttle will tell us what Prof. Stoney really did say, for if he puts the key characteristics down to what I should call defects in the keyboard, he is, as I believe, most certainly mistaken. **N. E. Child.**

OUR SPIRITUAL NATURE.

[21819.]—I have not had the advantage of reading any account of the researches or arguments of the scientists who are undermining spiritualism; but there is one view of the subject which has sometimes occurred to me to which I should like to call attention. "Sigma," in letter 21779, says the spiritual idea is independent of the material, and the loss of intelligence as the body wears out does not disprove the existence of the spirit. He then goes on to liken the spirit to a workman, and the body to his tools. Other correspondents have written in the same strain; and it would seem to follow that the faculties of the spirit become weaker in old age in consequence of the infirmities of a decaying body. But is that so? Is it not rather the spirit (assuming that we have a spirit independent of the body) which has its periods of rise, fulness, and decay? In youth the vital principle is strong and vigorous; in middle age it is robust; and then its powers become gradually impaired. So long as this vital principle continues active the body grows to its full stature, and (apart from disease and accident) retains its usefulness unimpaired. It is better at 30 than at 20, and there is no apparent reason why it should not be quite as good at 50 as at 30, and at 80 as at 50. Effete matters are constantly removed and worn out parts are changed. If the vitality which keeps it in good order for the first 30 or 40 years of life were to continue its efforts undiminished, why should the body wear out? It is true that in old age the eyes become dim and the muscles faint; but should not this feebleness of the organs be ascribed to the moribund condition of the governing spirit, rather than to the natural decay of the body itself, which is quite as subject to decay at 30 as at 80.

J. W., Birmingham.

THE GERMINATION OF WHEAT.

[21820.]—In making some experiments upon the germination of a fine sample of this year's wheat, I was surprised to observe that, within a week or ten days, each grain, as sown in ordinary garden mould in a flower-pot, outside a northern window, developed from the embryo quite a well-formed root or radicle, corresponding with the growth above of the plumule or young stem.

Now, as the albumen of the seed appeared to have been but little absorbed by the cotyledon of the young plant, I was naturally led to infer that the growth of the latter depended chiefly upon the pabulum which it derived through the radicle from the soil; and I, therefore, in order to test this conclusion, divided a few of the grains in halves transversely, and planted in a flower-pot as before those of the sections bearing the embryo, which, as most of your readers know, lies within a little oval depression at the narrowest end of the grain, that is easily detected, even with the unaided eye. As I had anticipated, all these half-seeds readily germinated, and, upon examination, the young roots appeared to have developed quite as fully as those of the perfect, undivided seeds, and within the same few days. The plumules, too, had correspondingly advanced in growth.

These phenomena in the case of wheat are, I think, not only interesting in a botanical point of view, but may also have a practical bearing upon the present costly operation of "sowing," which every agriculturist is naturally desirous, as far as possible, of economising. For, if a crop could be raised by sowing merely the *embryo halves* of the grains, and these halves could be readily made and separated by machinery or by hand; it is evident that the other, or, as it may be called, *infertile* half of the seed might be thus saved and, like the whole wheat, converted into flour.

I hope that these imperfect observations may give rise to further experiments in what may not, I think, be inappositely termed a *new field* of culture.

Stoke Newington. **W. H. O.**

REPLIES TO QUERIES.

⁂ *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[50746.]—**American Organ.**—Under the head of "Steel Reeds," p. 20, Mr. Scott replies to some remarks made on p. 580, by asking why, if the "bending," &c., does so much good, it is not applied to the bass notes? which he is sure want it as much as, if not more than, the upper notes. The simple and sufficient answer to this question is that the "bending," &c., *are* applied to the bass notes, even to the large sub.-bass reeds, in a genuine American organ. After that, I must begin to fancy it is a harmonium or an Anglo-American sham that your correspondent refers to; for certainly if he draws, say, the 8ft. C. of a genuine American organ, he will find that just as much care has been devoted to bending and twisting it as has been given to mid C.—Organon.

[50765.]—**The United States.**—"Num Dor," in his communication under the above head, asks me for further information concerning Dakota. He has heard a good deal about hurricanes and cyclones in the western parts of the United States, and somehow he has come to associate these severe visitants with this favoured region. It is not a fact, as he is inclined to assume, that "one's crops are liable to be destroyed at any hour," and men do not "think themselves lucky if they are able at times to hold on to a post that is not blown out of the ground." In reply to my correspondent's questions I would say that houses are not "lifted bodily up and carried miles away" in North Dakota; trains are not overturned and cornfields are not "cut as neatly as if the reaper had been over them." Really these stories are very strange to the people of North Dakota. "Nun. Dor." should remember that this country is full of men whose occupation it is to get up big gooseberry and big cyclone stories, and much that they write in fun is taken seriously. I am not prepared to defend this sort of writing, but the writers exist, and the fact has to be faced. There is another point to be remembered. In England a house is a brick and stone edifice which would require a very powerful wind to lift it up bodily. In the United States a house is liable to be of a very different material. In Mandan, for example, and in fact in some cities of 100,000 inhabitants, a majority of the houses are of lumber, and it needs a visit to this country to convince a foreigner that a wooden house can be made as comfortable, if not more so, than one of brick. Some roads are "impassable for loads" in Dakota, perhaps, but so far we of the west Missouri country do not suffer any great inconvenience from this. The railroad is the great load carrier in this part of the world and trains always run. My querist is troubled over a statement which he has met with to the effect that "the days are long—there was a day in June when scarcely an hour of the 24 was really dark." I never saw such a statement before regarding North Dakota. The days in the summer time are not as long here as they are in Edinburgh, Scotland, nor are they as short in the winter time. The question for immigrants is, "what is the probable length of their days," says "Nun Dor." This is a very practical question. Some emigrants have been here five or six years. It would be difficult to find a steady man who has been here that time who is not highly prosperous. Others have been here shorter times, and they also are accumulating wealth with more or less rapidity. The fact that no one wants to go back east to live after having spent some time in this glorious northwest is a great recommendation to it. The only poor men around here—poor in the English sense—are those whose habits or tempers or dispositions are such as prevent them from acquiring money.—R. M. Tuttle, Mandan, Dakota, U.S.A.

[51114.]—**Power of Engine.**—The ordinary way of ascertaining the h.p. of an engine is to

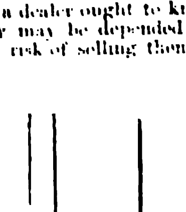
[illegible]

[illegible] —**Legal. Stepchildren.**—[illegible] his wife. The children's [illegible] —Lex.

[illegible] —**Legal – Secretary's Liability.**—Yes, secretary would be [illegible] holding possession.—Lex.

[51466.] —**Squinting.**—[illegible] with a shell [illegible] in the centre, in such a manner that the patient will be compelled to look through the [illegible] does not produce any effect in a week or two the effort to look through the hole will stretch the muscle "turning" the eye, take the [illegible] surgeon, who will, if he thinks it necessary, perform a very simple operation [illegible] he will think in [illegible] that above described [illegible] not advise without seeing the patient.—[illegible]

[51274.] —**Overstrained Piano.**—[illegible] or Mr Davies.—[illegible] could not have improved upon the advice given by "J. C. L.", but the [illegible] query was too [illegible] strongly reminded me of the kind of piano of which a maker would say at the first glance, "A new inside is evidently necessary, and as the case is somewhat old-fashioned, it would be better to renew that as well." This seems an extravagant picture; but I can assure "J. C. L." that I have now in my showroom a piano that I bought for £5—that is to say, it represents the piano, but it has been, piece by piece, renewed, until the carved legs and the metal plate are the only original portions left, and it was nothing but a vivid recollection of the trouble and expense entailed upon me that caused me to give the advice I did. "J. C. L." with his Cramer pianette, is not likely to, and I hope he never may, know what "trouble" of this kind is. I do not suppose that a "Puzzled Pianist's" friend is the only one, by a great many, who has made a pilgrimage in search of "Scott and Co. (from Collard and Collard)," and it may be of service to others of our readers to know that the name is fictitious, and together with such names as Tomkinson, Stoddart, Delamere, and, later on, with others of a more German sound, such as Steinmann, &c. (the most of them being only colourable imitations of well known firms), is not put upon pianos without good and sufficient reason. I do not go so far as to say that, because a name is fictitious, the piano is necessarily worthless, since many makers are in the habit of using copyright titles other than their own trade mark for their lower-priced pianos, but, though such pianos are not warranted, a dealer ought to know pretty well how much they may be depended on, and, if he [illegible] to take the risk of selling them, is responsible



[illegible] standing [illegible] well. A "Puzzled Pianist" does not, however, say that he purchased from a dealer, so I suppose he bought it at a sale, or possibly, from "a family leaving town." In either case he would be absolutely without redress. The question whether such a piano is worth the trouble and expense of repairing seems now more doubtful than before; but since he seems wishful to try his hand, I shall be glad to help him all I can. I do not know how the "Harmonious Blacksmith" proposed to apply an iron bracing at the head of the strings, but probably he intended it as merely an auxiliary support; but in this instance it would be wholly insufficient, since it would have to bear the whole of the strain, and there would not be enough room between the [illegible] and the strings to make it of sufficient strength. I should rather advise your correspondent

[illegible] between the [illegible] the plank. In the first [illegible] strings [illegible] the wrest-plank. [illegible] the plank may [illegible] The wood must then be [illegible] making of the plank when the strings are tightened. The stays [illegible] will be a better [illegible] of screws, as [illegible] will serve for a [illegible] itself when the pressure is taken off [illegible] it may be straightened by damping and pressure [illegible] When all is complete, I should not risk taking the strings up [illegible] at least, until it is seen how it [illegible] They may be made of deal, but [illegible] and varnished [illegible] of service. I shall be glad [illegible] by post.—W. H. Davies.

[illegible] —**Paint.**—I think the [illegible] will find something suitable in water glass.—Nov. Dun.

[illegible] —**Keeping Polyzoa.**—If you have failed to keep these alive, it must be because there is something wrong with the aquarium. [illegible] water from the [illegible], and have your plants in good condition. They ought to live for some time then.—[illegible] E. M.

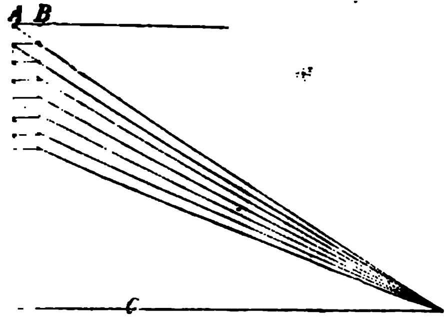
[illegible] —**Coal Mines.**—The statement is not correct now, if it ever was.—Durham.

[illegible] —**Cylinder, Largest.**—In Vol. XIV., [illegible], it is stated that the largest cylinder for a pumping engine is believed to be at the Lehigh [illegible] mines, Pennsylvania. The diameter is [illegible], and the stroke [illegible]ft. There must, I should think, be some larger than that; and the Lynden engine, for draining the Haarlemmer mere, has a cylinder 12ft. in diameter, with an inner cylinder of 7ft.; but I do not know length of stroke.—T. P.

[51313.] —**Forging Hard Steel.**—The published directions for treating "R. Mushet's Special Steel," issued by the makers, Samuel Osborn and Co., of the Clyde Steel and Iron Works, Sheffield, are as follows:—This steel should be worked at fully the same heat as ordinary lathe-tool steel. It should be heated gradually but thoroughly, so as to be quite ductile under the hammer, and the tool should be forged and finished off at a good heat. Avoid forging it too cold. When forged and shaped, the tool should be laid down to cool; and the cooling must not be hastened by dipping in water. Heat the steel before cutting it into lengths, as it cannot be nicked when cold. If smiths will attend to these instructions, they will have less trouble and waste than with ordinary cast steel.—A. P. S.

[51346.] —**Clarionet.**—In reply to "Old Blowhard's" remarks on p. 19, when I said that the bell mouth on the end of a clarionet increased its loudness, I meant to have said "its timbre." I have just tried this instrument with and without the bell mouth, upon a listener in the next room, who preferred the tone without the bell. I am only in the stage referred to by "O." (see 51432, p. 20), and have no doubt that the neighbours would gladly assist at my funeral. I do not find that removing the bell "sharpens the pitch" of any note whatever. The diameter of bore given as $\frac{5}{16}$ is either a mistake of the printer, or my own, as it should read $\frac{9}{16}$; also the name of the maker should read, Button and Co., London. I am of opinion, so far, that a better tone can be obtained from larger bored instruments, and am experimenting in this direction. As regards the beech reeds, I find that they become soft if kept long in the mouth, but are useful for a beginner to pare away at, until he learns the art of voicing, as I could not run that scale with a reed fixed by "The Man in the Music Shop." For purity of tone, the Spanish cane is unapproachable.—A., Liverpool.

[51346.] —**Clarionet.**—I regret that, as I am from home at present, I cannot answer the queries of "J. J. D." for a fortnight; also, I am rather in doubt as to which kind of clarionet he wants to make, but I presume it will be the Albert model. As to the scale of distance, it can be got in a variety of ways; the simplest is by drawing. Make two perpendicular lines 24in. long, 2in. apart; then at the foot of these draw a longitudinal line 36in. long; from the end of this last line draw a line to the top of the first 24in. line, and then at the point that this angular line crosses the second 24in. line, draw a parallel line. I inclose a rough sketch. A B are the 24in. lines, 2in. apart; C is the 36in. line. The small parallel lines are the divided scale. By proceeding thus you can get the proper distances for sounding tubes or strings, and by varying the distance apart of the 24in. lines any distance can be so divided. The other way is more correct, and consists in dividing the total distance into 1000 parts, and then measuring off the distance of each note from the end of the scale. These distances I will send to "J. J. D." when I get home. As to the bore of clarionets, the best bore for B flat clarionet is 15 millimetres, or $\frac{6}{10}$ths of an inch. As to the others, it is a matter of opinion entirely: each maker having his own idea on this subject. But the bore required can be easily calculated from the B flat bore, and taking the B flat bass clarionet at 22 millimetres; any clarionet can thus be given its best size. As to the question of notes, it would require too much space to make this clear: but if there is sufficient interest taken by the readers of the "E. M.," I will endeavour to give a short article on the subject of "Tubes with Sounding Holes." Meantime I refer "J. J. D." to "Böhm on the Flute," translated by W. S. Broadwood, published by Rudall, Carte and Co., price about 2s. 6d. As to the latter part of query—viz., kind of brass, I don't understand it, as there is no brass about a clarionet, not even in the tone! As to the measurements given by "A., Liverpool," they are quite extraordinary, as I never saw yet a clarionet with as small a bore as $\frac{5}{16}$ths of an inch. Again, the "reed centre" is very indefinite; and spruce timber is certainly not a good material, either for tone or workmanship. I think when one goes to the trouble of making a clarionet, it must be done thoroughly, and not merely a toy product, which is no credit to the maker.—Vulcanite.



[51357.] —**Faraday.**—You couldn't have a better book than "Faraday as a Discoverer," by Prof. Tyndall (published by Longmans, Green, and Co.)—R. A. R. Bennett.

[51362.] —**Legal—Advertising Lotion.**—No person can by law sell any poison but a duly registered chemist and druggist, under a penalty of £5, or a legally-qualified apothecary or member of the Royal Hospital for Veterinary Surgeons of Great Britain.—Lex.

[51387.] —**Legal—Agreement.**—A contract not under seal may be waived or abandoned by word of mouth only, even, it would seem, if it was one which the law requires should be in writing; but in the latter event it would best be done by some writing.—Lex.

[51415.] —**Legal—Unfulfilled Lease.**—I do not see what you can threaten the farmer with. If he has made a fortune, there can be no probability of his being a bankrupt; but if he is made one, or neglects to pay the rent, or makes any breach under the covenants of the lease, you have your right of re-entry, and for any rent due at the time of his bankruptcy you could recover. The trustees under the bankruptcy would have all the powers to sell or disclaim the lease for the benefit of his creditors. In fact, I think you should not be too hard, but let him or his son have a lease at what you know is the proper amount of present rent, and save all annoyance and costs of any forfeiture or bankruptcy; and although it would be at a reduced amount, I consider you would be the gainer in the end, and close all contention and litigation.—Lex.

[51424.] —**Electric Time Ball.**—The ball may be raised by a line passing over a pulley in the top of the pole on which the ball slides. This line is wound on a barrel which has another line carrying a counterweight wound on it; a buffer spring is also placed at the bottom of the pole for the ball to fall on. The barrel is held, when the ball is up, by a lever which rests on a trigger. When the circuit is completed, the electro-magnet attracts the trigger, and allows the lever to fall, releasing the barrel, and the ball slides down the pole. I will give you a sketch of the apparatus, if necessary.—W. Baldwin, 110, Richmond-road, Dalston.

[51432.]—**Clarionet or Oboe.**—To "O."—Will you kindly state whence and how the reed in its unworked state is to be procured?—so as to be sure of the time it was cut during its growth; for instance, whether of last year's or this year's growth. Older reeds are too brittle, and never can give the desirable soft tone for drawing-room.—P.

[51432.]—**Clarionet or Oboe.**—Would "O." (page 20), or someone else who knows all about oboes, inform me whether oboe playing is injurious to the health in any way? I have heard it said that it was the oboe that killed Barrey (a great oboeist) and one or two others. They say the inevitable fault is chiefly due to the reed, and the bore that is connected with it having such a small aperture, thus preventing a proper amount of breath to pass from the lungs, and so causing a severe pain to be felt across the chest if played for any considerable length of time. Would "O.," or any other kind reader, inform me whether there is any foundation for this statement. Also the time it would take a person to master the reed sufficiently to be able to play moderately easy music.—E. T. S.

[51445.]—**Legal—Building Society Mortgage.**—Your name is perfectly good on the deeds and mortgage, and the house would be your separate property under the Married Women's Property Act, 1870, sect. 5; but to secure it from going to your husband on your death, you must make a will. This can be done, notwithstanding the mortgage may not be paid off, or else it would go to the husband only. You must, during your lifetime, keep up your instalments, and your successor must do so in the event of your death.—Lex.

[51464.]—**Legal—Medical Electrician.**—B. cannot prevent A. from publishing his own testimonials. A. should prevent B. by giving notice in the local newspapers; and if he continues after that, get an injunction from one of the courts.—Lex.

[51493.]—**Laundry Stove.**—If "Economist" will advertise his address, I may be able to put him right.—Vulcan.

[51494.]—**Lime Juice.**—Try one pint expressed juice, one pint water, and 3½lb. best lump sugar; warm till the sugar has dissolved, and strain through a jelly bag.—Fred.

[51497.]—**Small Brace.**—Thanks to "W. E. G." and others, but it is not the "Archimedean" brace I am meaning, as I have had one of these; but one worked simply by the hand. Of course the Archimedean requires the breast or other power for pressure.—E. Owen.

[51500.]—**Mathematics.**—The way to find the cubical content of the two heaps of stones is as follows:—To the sum of the areas of the two ends add the square root of the product; multiply this sum by the perpendicular height, and one-third of the product is the solid content. First heap, $110 + 25 + \sqrt{(200 \times 25)} \times 5 \div 3 = 135 + 52{\cdot}4 \times 5 \div 3 = 312{\cdot}3$ cub. ft. Second heap, $200 + 75 + \sqrt{(200 \times 75)} \times 5 \div 3 = 275 + 122{\cdot}4 \times 5 \div 3 = 662{\cdot}3$ cub. ft.—G. Worland.

[51500.]—**Mathematics.**—Supposing

x = sq. feet area of base
y = do. of top
z = do. of midway horizontal section
and h = vertical height in feet.

According to Nesbit's "Mensuration"—

$$\frac{x + y + z \times 5}{6}, \text{ giving cubic contents.}$$

1st heap contains—

$$\frac{110 + 25 + 240 \times 5}{6} = 312{\cdot}5 \text{ cub. ft.}$$

and 2nd—

$$\frac{200 + 75 + 525 \times 5}{6} = 666\tfrac{2}{3} \text{ do.}$$

—Buttershaw, Sept. 8.

[51500.]—**Mathematics.**—Contents of heap No. 1 = 312½ft. cube; contents of heap No. 2 = 666⅔ft. cube. Rule (as given by Rankine).—To the areas of the top and bottom add 4 times the area of a cross section midway between and parallel to the top and bottom, divide the sum by 6 for the mean section, and multiply by the perpendicular height. This may be proved by calculating the heap as being made up of the centre square and the wedge-shaped sides and corners. It will be seen that the above answers differ from those given in last number, and by the following example it is shown that the methods employed in the three first replies are wrong. Thus, required contents of a heap 6ft. by 6ft. on base, 2ft. by 2ft. on top, and 4ft. high.

$$\left.\begin{array}{r} 6 \times 6 = 36 \\ 2 \times 2 = 4 \\ 4 \times 4 \times 4 = 64 \end{array}\right\} = 104 \div 6 = 17\tfrac{1}{3} \times 4 = 69\tfrac{1}{3}.$$

Answer, 69⅓ft. cube.

Now, by the method shown by "Salvo Jure," "G. H. F.," and Evans, the above heap would contain 80ft. cube. According to A. McCormack, it would contain the proper amount, 69⅓; but by his method it is necessary to extract the square root of a number, which trouble is saved by the rule given above.—Ditton.

[51500.]—**Mathematics.**—The three correspondents who send answers to these questions will find, on consideration, that their solutions are incorrect. The only elementary method of solution consists in dividing the irregular solids into 9, more regular figures by 4 vertical planes, each containing one edge of the upper surface. These four planes will divide the figure into a central prism, four rectangular wedges, one on each side of the prism, and four pyramids, one at each corner. Thus, in question (1), with base 10 × 11, top 5 × 5, and height 5ft., we shall have prism, of which ends are 5 × 5, and height 5 = 125. Two wedges will be each 5 × 2½ × 5 high; the other two 5 × 3 × 5 high. The volume of a wedge being half of the corresponding prism, we have volume of first two wedges = 5 × 2½ × 5 = 62½, volume of second couple = 5 × 3 × 5 = 75. The pyramids at the corner will have bases measuring 3 × 2½, and their volume is found by taking ⅓ of height by base, or $3 \times 2\frac{1}{2} \times \frac{5}{3} = 12\frac{1}{2}$. There are four such pyramids.

$$\therefore \text{ Volume of pyramids} = 50.$$

$$\text{Total volume} \left\{\begin{array}{lr} \text{Prism} & 125 \\ \text{Wedges} & 137\frac{1}{2} \\ \text{Pyramids} & 50 \end{array}\right.$$

$$\underline{\overline{312\tfrac{1}{2}}} \text{ Ans.}$$

Similarly for the second question—

$$\begin{array}{lrcl} \text{Base } 20 \times 10, \text{ top } 15 \times 5, \text{ height } 5 & & & \\ \text{Prism} & 15 \times 5 \times 5 & = & 375 \\ \text{Wedges} & 15 \times 2\frac{1}{2} \times 5 & = & 187\frac{1}{2} \\ \text{Wedges} & 5 \times 2\frac{1}{2} \times 5 & = & 62\frac{1}{2} \\ \text{Pyramids} & 2\frac{1}{2} \times 2\frac{1}{2} \times \frac{5}{3} \times 4 & = & 41\frac{2}{3} \\ \hline & & & 666\frac{2}{3} \end{array}$$

The above results may be checked by estimating volume by integral calculus.
For question (1), one slant side increases from 5 to 10, and the other from 5 to 11.

$\therefore$ At a distance x below the top we have for the length and breadth of the rectangle $\left(5 + \frac{6x}{5}\right)$ and $(5 + x)$.

$$\therefore \text{ Area of rectangle} = \left(5 + \frac{6x}{5}\right)(5 + x) = 25 + 11x + \frac{6x^2}{5}.$$

$$\therefore \text{ Volume of small element of thickness } dx \left(= 25 + 11x + \frac{6x^2}{5}.\right) dx$$

$$\therefore \text{ Volume} = \int_0^5 \left(25 + 11x + \frac{6x^2}{5}\right) dx.$$

$$\text{Now } \int \left(25 + 11x + \frac{6x^2}{5}\right) dx = 25x + \frac{11x^2}{2} + \frac{2x^3}{5}.$$

$\therefore$ Volume = 125 + 137½ + 50 = 312½ Ans.; and similarly for the other one.—John F. Wilkinson, A.R.S.M.

[51502.]—**Small Dynamo.**—If "A Would-be Dynamo Maker" and Mr. Sutton will advertise their addresses I shall be very pleased to send them a description of my machine on my return home, which will be in a few weeks.—W. P. A.

[51503.]—**Legal—Will.**—The will should be proved by the personal representative of such deceased executor. The widow is not bound to do so; but she may take out letters of administration if executors renounce. Why not get the eldest son of the deceased brother to do so?—Lex.

[51504.]—**Colouring Photos.**—Have you tried the old-fashioned plan of licking the photo. with your tongue? Not very pleasant, perhaps, if the photo. is large; but there is nothing better that I know of, unless oil colours would suit you.—W. Robinson, Jun.

[51508.]—**Wet Plates.**—Your bath is evidently contaminated with organic matter of some kind, and you cannot do better than expose it to strong sunlight until clear; then filter and try again. I do not know what Foulke's cement is composed of; but if you use shellac for cementing your dipper, you will be all right. It is not by any means absolutely necessary to protect the collodion and bath from light when not actually in use; but the latter should certainly be closely covered, to keep out dust, flies, &c.; hence it is the general practice to keep it in a case or box of some kind. If you should still be troubled with the spots, describe them more particularly, as there are spots and spots.—W. Robinson, Jun.

[51509.]—**Rabbits.**—I have put rabbits to breed at four months old; but six months is a better age, as the young are stronger. There is a good book published by Routledge and Sons, at 1s., called "Pigeons and Rabbits," by E. O. Delamer.—Ouest.

[51513.]—**Architectural Photography.**—Ross's triplet, or Tench's planographic, would probably answer your purpose as well as any other; supposing them to be in good order and condition, and not defective in any way; and the exposure, using gelatine plates, would not be very long, unless the light were bad, or you were compelled to use a very small stop.—W. Robinson, Jun.

[51514.]—**Power of Engine.**—17 × 17 × ·7854 = 226·9806 area of piston, 2 × 150 = 300ft. piston travel, 226·9806 × 300 × 100 ÷ 33,000 = 206·3 h.p. with one cylinder. Multiply that by 2 gives 412·6 h.p. with two cylinders. The wheels have nothing to do with the answer.—H. W.

[51514.]—**Power of Engine.**—As the speed of piston is 150 × 4 = 600ft. per minute, and the effective pressure per sq. inch throughout stroke is 100lb. on piston, and the quotient of any steam-engine cylinder squared divided by 14 gives the indicated horse-power of that engine for piston speed 300ft. per minute, and pressure 10lb. per sq. in., inasmuch as $17^2 \div 14$, or $289 \div 14 = 20{\cdot}64$, so 17in. piston 10lb. pressure, 300ft. speed, gives 20·64 h.p., 17in. piston 100lb. pressure, 300ft. speed, gives 206·4 h.p., 17in. piston 100lb. pressure, 600ft. speed, gives 412·8 h.p.; for one cylinder or for two, speed gives 825·6 h.p. Another way.—As the cylinder's diameter squared gives the indicated horse-power of steam-engine whose piston speed is 420ft. per minute, and effective pressure per sq. inch, 100lb. per sq. inch. By double slide rule: Setting 420 on slide $\frac{B}{C}$ opposite 17 on line D, and 100 on slide N opposite 600 on slide $\frac{B}{C}$; then opposite 100 on slide N is nearly 413 h.p. on A for one cylinder as before.—Buttershaw, Sept 8.

[51514.]—**Power of Engine.**—Multiply the area of the cylinder in inches by the speed of piston in feet per minute, and this product by the pressure of steam in pounds. Divide the result by 33,000 = horse-power of one engine. To work this out in your case:—17 × 17 × ·7854 = 226·98, say, 227 (to clear the question of decimals) = area of cylinder. I presume you mean 150 *revolutions* per minute, if so, the speed of piston will be 2ft. × 2 × 150 = 600 speed of piston in feet per minute. Then—

$$\begin{array}{r} 227 \text{ Area of cylinder} \\ 600 \text{ Speed} \\ \hline 136200 \\ 100 \text{ Pressure} \\ 33{,}000)13620000(412\frac{3}{4} \\ 132000 \\ \hline 42000 \\ 33000 \\ \hline 90000 \\ 66000 \\ \hline 24000 \end{array}$$

$$\frac{24000}{33000} = \tfrac{3}{4}$$

That is 412¾-horse-power for one engine, or 412¾ × 2 = 825½ horse-power for the whole engine. If your correspondent or any other reader does not understand the use of decimals, here is a handy rule for finding the area without their use:—

$$\begin{array}{r} 17 \\ 17 \\ \hline 119 \\ 17 \\ \hline 2)289 \\ \hline 2)144\frac{1}{2} \\ 7)\ 72\frac{1}{4} \\ 10\frac{1}{4} \\ \hline 227 \end{array}$$

—Tyke.

[51518.]—**Paint for Brine Cistern.**—The best paint to stand the action of brine is an anti-corrosion paint, sold in London; but it is against the rules to give the address. If "Brine Spring" would advertise his address, I should be happy to inform him where he can purchase it.—Machina.

[51525.]—**Magnetism—Science Examination.**—I am much obliged to R. A. R. Bennett for his reply: but it lacks the information required. William John Grey evidently knows what is required. Permit me to say that it is not required which, when cold, just flows, having lost the gelatinous texture. In this liquid dissolve 8 parts of gum arabic, in lumps, adding a little water if needful; then add 4 parts of glycerine, and stir in well. Evaporate the water from the medium over hot water, and keep the medium in a covered vessel. It will not dry up. To make colours:—Take a quantity of dry colour in powder, by measure, and about the same quantity of the medium, and mix well together, using water, if needed, to assist the mixture. Some colours, usually the most costly, are fine enough as sold to be mixed at once with a palette-knife. Others, coarser, need grinding on a stone with a muller. Some colours require more medium, others less. The coarser colours, such as yellow ochre and Vandyke brown, the most. Gamboge requires very little. One part of medium to 4 of colour will do. For most colours equal quantities are about right. By this method colours can be home-made at a trifling cost fully equal to the best sold. Pans of the size for the usual water-colour boxes can be made of card, folded up and bound round with a pasted slip of paper.—Fisherman.

[51591.]—**Cigarette Machine.**—The secret in making cigarettes by hand is that you, when you are lapping the paper, pull with both hands as much as the paper will allow. Don't put too much tobacco in till you can make them well.—J. H. Schucht.

[51592.]—**Utilising Vegetable Fibres.**—I shall be glad to give inquirer full details of machines as largely used in Mauritius, and East and West Indies, and at the Cape, if he will advertise his address.—Jonson.

[51595.]—**Chinese White.**—Chinese white is oxide of zinc; it is prepared by grinding up the oxide with a mucilage of gum tragacanth to the required consistency, and then adding (for quantity to fill ordinary Chinese-white bottle) 12 drops of thick mucilage of gum arabic, and 6 drops of pure glycerine. Make the mucilage by putting a piece of the gum into a small quantity of water until it swells up and absorbs water, and then beat it into a pulp. When the colour gets dry, grind again with a little of the medium.—E. A. H.

[51596.]—**Platinum.**—No single acid acts on platinum, but nitro-hydrochloric easily dissolves it, so that if you are using it in a battery, see that your nitric acid is pure and free from hydrochloric. Caustic potash solution does not act on it, but at high temperatures caustic potash, potassium nitrate, and lithium hydroxide corrode it. Chlorine water also acts on it, and mixtures of chlorides and nitrates.—E. A. H.

[51596.]—**Platinum.**—Yes; caustic potash does act injuriously upon platinum when heated on a piece of it. A mixture of hydrochloric and nitric acids dissolves it entirely. Harcourt and Madan ("Practical Chemistry," page 7) say that the following substances ought never to be heated in a platinum crucible:—Substances evolving chlorine or sulphur, caustic alkalies or barium hydrate, cyanides, chlorates, nitrates, easily reducible metallic salts, or the corresponding metals—*e.g.*, lead, silver, or tin.—R. A. R. Bennett.

[51597.]—**Oxide of Copper.**—The simplest method to make oxide of copper is to heat the nitrate.—E. A. H.

[51597.]—**Oxide of Copper.**—On adding solution of potassic hydrate to solution of copper nitrate you will get a light blue precipitate; on boiling this precipitate it will turn black. This black precipitate is the copper oxide you require. Or if you want *red* copper oxide, dissolve some grape sugar in a little water (if the liquid is not clear, filter it), and add a few drops of copper nitrate. On adding potassic hydrate to this solution no precipitate will be produced, if the grape sugar is present in sufficient quantity. If any precipitate is produced, go on adding caustic potash, drop by drop, till the precipitate is dissolved. Now heat the mixture to boiling, and you will get a yellow precipitate, which immediately changes to a red one. This red precipitate is copper protoxide, or red oxide of copper.—R. A. R. Bennett.

[51600.]—**Chemical.**—Owing to the citric acid, which will not keep in solution. Try the addition of a drachm or so of glacial acetic acid.—W. Robinson, Jun.

[51600.]—**Chemical.**—I don't think it is possible to prevent the fungus from appearing, unless some other chemical was put in. Solution of tartaric acid behaves in the same way.—R. A. R. Bennett.

[51601.]—**Photographic.**—There is a book on Theoretical Photography" among the "Text-oks of Science," I think. I do not know the blisher's name.—A. T. P.

[51601.]—**Photographic.**—In Abney's "Trea-se on Photography" (one of Longmans' Science t Books) the subject is treated at much greater than in his "Instruction," and more in —Ditton.

[51601.]—**Photographic.**—Hardwich's Manual deals very fully with the theory of photography. Mine is an old copy, dealing chiefly with the wet process, but no doubt the new edition (see advt.) will be brought well up to date.—W. Robinson, Jun.

[51602.]—**Testing Piano.**—(1) Buy no piano which is less than 4ft. in height. Pianettes are only fit for schools for children to practise on. In a private house where there is good music expected, they will not answer on account of the bass strings being too short, therefore the bass produces an indistinct noise only. (2) See that there is an iron frame on which the strings are fastened; it will cost a little more, but then you are safe that the case will not collapse, and it will require less tuning. (3) See that it has a check-action. After the hammer has struck the strings the check holds it firm and ready for another blow. If there is no check the hammer is not in the power of the player, because it is dancing about. (4) See that the holes in the front of the keys are lined with cloth, as the bare wood working on the pins will make a rattling noise after being used for a time. (5) Raise the dampers and strike some chords, and see that the tone is sustained 45 seconds. Sustaining quality is the test for good quality. If the tone is short, it is evident that there is some interference somewhere, and that interference alters the quality of the tone also, but not for the better. (6) See that the pins (the tuning pins) are very tight, if they are not, the piano will not stand in tune.—J. H. Schucht.

[51606.]—**Repairing Engine.**—(1) Are you quite sure that there is no binding? for I have known a case where the engine could not be run at full speed through the piston rings being too tight. (2) The main valve may be a very large one; if so, a great deal of friction will be the consequence. (3) The packings of air-pump (if condensing) may be done: if so, a certain amount of power will be lost through a defective vacuum. (4) The piston may be bad, and allow steam to pass from one side to the other, and every pound of steam lost in this way will be equivalent to a loss of two pounds. If you could disconnect the shafting, and apply the indicator, and take a friction diagram, any of the above defects would be revealed. The first would be revealed by the average pressure of the diagram, which should not exceed 4lb. per square inch, if there be no excessive friction of working parts. (2) A large valve would also give a greater average pressure on diagram, but a proof of the great friction of a valve is the shake or vibration of valve rods. (3) If the cause is in the air-pump, it will plainly show on diagram, for the back-pressure line should be 12lb. below the atmospheric line, otherwise the vacuum will not be good. (4) If the piston is leaky, the pressure at the end of the stroke will be higher than that due to expansion, and will be shown by the back-pressure line rising. There are many other causes which may exist, such as the opening and closing too soon, and opening and closing too late, of exhaust, &c.—all of which would be detrimental to the power of the engine. But I should advise you to take a pair (one from each end) of diagrams, and send them to the "E. M.," with particulars, and you shall have further and more reliable information.—Engineer, Dewsbury.

[51608.]—**Patterns for Boots and Shoes.**—If "Politzer" will advertise his address, I will send him the book he wants.—E. Fitch.

[51617.]—**White Metal.**—White metal is prepared by melting together tin 84 parts, lead 16, antimony 5, zinc 1, and copper 4.—E. A. H.

[51621.]—**Glue.**—The "Workshop Receipts" says waterproof glue is prepared with skimmed milk instead of water, about two quarts to 1lb. of glue. Acidulate with acetic acid.—T. P.

[51621.]—**Glue.**—Take shellac 3 parts, and india-rubber 1 part by weight. Dissolve each separately in ether free from alcohol, then mix the two solutions together and keep in a well stoppered bottle. This glue will resist the action of water, hot or cold, acids, and most of the alkalies. This glue may be thinned by adding more ether, and used as a waterproof varnish for applying to the joints in leather where it is sewn.—Harry Scott.

The importation into the United States of tin-plate for the calendar year 1882 amounted to 240,000 tons, valued at £3,600,000 in dock at Liverpool; but by the time duties, freights, interest, and importers' and jobbers' expenses and profits were added, these represented a cost to the American consumer of not less than £6,000,000.

The American *Granite Cutters' Journal* says:—"From surveys and calculations made by Mr. J. A. Farrington, civil engineer, the famous Washington boulder, near Conway Corner, N.H., is found to measure 30ft. in height, 46ft. in length, 35ft. in width, and to weigh 3,867 tons. This is the largest known *isolated* piece of granite in the world."

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list and send what information they can for the benefit of their fellow contributors.

QUERIES.

[51622.]—**Chemical.**—Can ammonia carbonate be readily or easily transformed into—

1. Hyposulphite of ammonia.
2. Bisulphate ,, ,,
3. Bisulphite ,, ,,

If so, how? Would the carbonate be the handiest salt of ammonia for the production on the small scale of the above three salts, or is any other (obtainable of a chemist) preferable for the above purpose? Directions how to produce these three salts of ammonia will greatly oblige?—Ship Canal.

[51623.]—**Steps and Landing.**—Would any of your readers kindly suggest the best method of reducing the noise caused by the tramping up and down wood steps? Would coating them with sheet lead have the effect, or could any one recommend some other method which would be effectual as well as cheap and durable?—T. W. T.

[51624.]—**Horse-Clipping Machine.**—Could some one kindly give me instructions how to sharpen and set above?—W. L.

[51625.]—**Hydropathy.**—I feel grateful to Mr. Fennessy and "J. W. C." for their kind suggestions. As the latter has volunteered further information, I shall, as desired, state the symptoms. I am as a rule despondent, but unusually so in wet weather. I suffer at times from giddiness, the result, I believe, of flatulency. I have an exceedingly weak stomach and am seldom free from a foul tongue. I also suffer from constipation and am very hard to operate upon. There is waste from the generative organs, and I generally have a feeling of lassitude. I also suffer from loss of memory. "J. W. C." says that I should take but three meals a day, and that I should take porridge for breakfast and supper. Does he mean that supper is to be the third meal? If so at what hour should I take it? How long should I remain under the cold shower? "J. W. C."'s kind instructions on these points will much oblige.—Sufferer.

[51626.]—**Polishing Shells.**—I have some large specimens of shells. How can I polish them?—H. A. C.

[51627.]—**Removal of Chimney Shafts.**—Three or four years ago the Royal Engineers at Chatham Dockyard blew down some chimneys with guncotton. Can any of your correspondents give some particulars of heights, &c., and why they were not taken down piecemeal—was it for experiments? Did the process of blowing down destroy many of the bricks?—W. B.

[51628.]—**Wrought-Iron Chimney Shafts.**—Have any of your correspondents practial experience of these? Are they cheaper and do they require many repairs?—W. B.

[51629.]—**Watch Jobbing.**—I have a watch that goes too slow; the regulator is pushed to the end. I have tried to regulate it by simply taking up, or shortening, the spring, but I have spoiled the beat. Will "Alfojoe" or some one kindly give me the best and easiest method of taking up or letting out the spring without spoiling the best?—J. J.

[51630.]—**Organ Pipes, &c.**—Can any reader give me any information respecting the measurement of the above, and if there is any book published about the construction of an organ? I want to make pipes for a 5-octave organ and 1½ row of pipes. I want to make what is called an eight-foot tone.—G. R. S.

[51631.]—**Transmission of Sound.**—Allow me to ask for information respecting the transmission of sound in solids, especially iron. Is it by alternate spaces of condensation and rarefaction as in air? If so, what are the size of the waves, and is there any mode of demonstration? Do the particles of iron move in these spaces, and what is the rate of transmission? Any other information on the subject, especially if discovered during the last ten years, will oblige.—G. Baxter.

[illegible]

[illegible]—Setting Valves, &c.—Would some cor[illegible] the best way to set the eccen[illegible] and how to calculate [illegible] Also length of piston-[illegible] rods, &c.—A. S.

[illegible]—Cutting Keyways.—Can any reader tell [illegible] of a good rule as to size and depth of keyways in wheels of different sizes, &c.?—A. S.

[illegible]—Fixing and Erecting Machines, &c.—I should be greatly obliged if some of our practical [illegible] readers will tell me the best way to fix a line of [illegible] in a direct line with an existing shaft, also one [illegible] with another existing shaft? Also, when you [illegible] an engine, some mills and gearing to fix in new [illegible] how is it best to set to work, so as to make a good

[illegible] I want to know rules [illegible] so as to get [illegible]

[illegible]—[illegible] Calculating Machine.—I [illegible] a description of the [illegible] machine? It [illegible] Cyclo[illegible] impossible to form [illegible]—Joseph Ed[illegible]

[illegible]—Legal.—[illegible] "Lex." [illegible] a back street (10ft. [illegible] Each tenant has [illegible] back entrances, and [illegible] for removing ashes [illegible] the above. The proprie[illegible] have been served with the following notice:—"Now, therefore, the said urban [illegible] give you notice, in pursuance of [illegible] to level, pave, flag, channel, [illegible] the same within the space of 28 [illegible] in the manner following." [illegible] in which they require it to be [illegible] sanitary authority the power to [illegible] proprietors to make good the above [illegible] compel it to be done in what[illegible]—H. J.

[illegible]—[illegible] and Equilibrium.—[illegible] sustaining one cwt. [illegible] me hour by work done on the [illegible]

[illegible]—Chimney Flues, &c.—Ought the internal [illegible] chimney-shafts be larger diameter at [illegible] and if so, what is the reason?—[illegible]

[illegible]—The Australian Colonies.—Is there [illegible] an architect and surveyor in any of the [illegible] which is the best to go to? What [illegible] and are situations hard or easy to [illegible] on the surveying staff of any [illegible], and if so, by what means?—[illegible]

[illegible]—Bee-keeping.—I have a skep of young [illegible] about two pounds of honey [illegible] tell me what I can feed them [illegible] so that I can keep them alive [illegible] winter?—[illegible] Bees.

[illegible]—Decomposition of Water by Electric [illegible]—What [illegible] of current is required, and [illegible] it?—Will some experi[illegible]—Johnson.

[illegible]—Disinfecting Pictures.—How are gold-[illegible] work pictures, and photo[illegible] the walls of a room during its [illegible] case of small-pox, to be thoroughly [illegible] with sulphur (the means em[illegible] the other contents of the room) [illegible] impracticable?—Rudolph.

[illegible]—Cygni.—Would Mr. Holmes kindly give [illegible] its components? I believe he [illegible] your readers if he will do so. And [illegible] would he also state the aperture he [illegible] the power of his eyepiece?—H. D.

[illegible]—Sleeping Carriages.—Will some corre[illegible] give particulars and principal dimen[illegible] carriages (not the Pulman cars) in [illegible] and North Western, Great Northern, [illegible] expresses?—W. H. Y. T.

[illegible]—Spiral Turning.—In Vol. XIV., No. 360, [illegible] making spiral twist. Would Mr. [illegible] tell me how it works, and [illegible]—H. P.

[illegible]—Stinking Indiarubber Gaspipe.—I [illegible] any reader can tell me how to prevent [illegible] from emitting such a constant [illegible] I suppose, arises from becoming [illegible] of carbon, and oblige?—D. C.

[illegible]—Surveying.—Would some kind reader tell [illegible] the area of circular, triangular, and five-[illegible] and fields which have rivers run[illegible] in all directions? How may I [illegible] the number of tons in old and new hay [illegible]—Agriculturist.

[illegible]—Magnetism.—A compass needle is [illegible] a current of electricity either under [illegible] Will the magnetism of the needle be altered, [illegible] by sending an occasional current [illegible] south end to the centre or point by which [illegible] suspended?—H. J. W., Everton.

[illegible]—Will—Administration.—To Mr. W[illegible].—Three brothers and a married sister. [illegible] intestate. The eldest of the others ad[illegible] divides the property between them. In con[illegible] the Married Woman's Property Act now, I [illegible] law in Ireland, has the husband of the sister any claim on her share?—M. P.

[illegible]—Kidney Beans.—Is there any reliable way of [illegible] kidney beans (scarlet runners), so that they may be used as a vegetable for several weeks after being [illegible]? I have tried a recipe—beans and salt in layers—but they are not useable.—Kaney.

[51684.]—The Other Side of the Moon.—The moon as we all know, presents always the same hemisphere to the earth, and we therefore know nothing of the configuration of her other side beyond what might be inferred from the appearance of the half we are so familiar with. This mystery of the moon, however, was increased tenfold a few years ago by the discovery that her centre of figure and centre of gravity did not correspond—the latter being about eight geographical miles nearer the "other" side. The consequences are startling in the extreme. It follows that all the water which may be on her surface, with any atmosphere she may possess, and, therefore, all life such as we are acquainted with, would be attracted by the force of gravity to that tantalising "other side" which is for ever turned from us. I need not dwell on the thrilling pictures of life and movement that arise in the mind—the possible cities, and seas and rivers with their craft, and the busy selenites at their daily occupation (for with our present telescopes they might be discerned), my object at present being to ask "A Fellow of the Astronomical Society," or some other reader, to be so kind as to give me some more particulars regarding the discovery, which I have not seen any reference to in the "E. M." for some time. Who made the discovery (a Frenchman, I think), and under what circumstances? I should also be obliged if particulars were given of the way in which the calculation was made, along with some indication of the effect of the discovery upon the question of inhabitants?—W. G. C.

[51685.]—**Loose Teeth.**—H. W. S. has for some time past been learning to play the flute, and finds that the pressure of the "mouth hole" or "embouchure" against the lower lip (which is necessary in the upper octaves) has caused his front teeth to become quite loose. Can any reader name anything that will tighten them, and oblige?—H. W. S.

[51686.]—**Historical.**—At what date was Christianity introduced into Britain? None of my books agree on the subject?—Euskarian.

[51687.]—**Railway Speed.**—Will some one kindly give the average speed of (1) The Irish Mail? (2) The Scotch Mail? (3) the Highland Express, and oblige?—Euskarian.

[51688.]—**Hydraulic Lift.**—I should feel extremely obliged if any one of our readers would inform me where the largest hydraulic lift is to be seen, and what weight it will raise?—W. J. Bramwell.

[51689.]—**Spectacles.**—I shall feel obliged if some brother reader will answer the following questions:—I am very shortsighted and my eyes are of different foci; I wear glasses in the streets and use a weaker pair for writing. (1) Ought my spectacles to have glasses of different foci, so as to bring the image sharp in each? (2) Ought the glasses for outdoor wear to have such foci as to bring the images of the most distant objects sharp in each eye—I have been told they should not be so deep? (3) Does the eye at 30 years of age tend to alter so as to require glasses of deeper curve, or the reverse?—Old Sminos.

[51690.]—**Metaphysics.**—Will any of our readers inform me where I can get the best work on metaphysics for self-instruction?—T. H.

[51691.]—**Australia.**—Would any fellow reader say if there is any opening or prospect for an electrical engineer in Australia? I understand the working and construction of dynamos and batteries, also the steam-engine?—Pluck.

[51692.]—**Photography.**—I cannot get sufficient density in my negatives this year; have been using "Archer" and "Kingston Special." I have previously used "Uranium" plates, but the photographic stores do not keep them now; can you tell where I can procure them? I have been quite successful with them. I use Edward's Glycerine Developer. I have new ammonia, as I thought it might be that. (2) I have heard that there is a preparation can be used to intensify over-exposed plates after they have been fixed and dried. Can you tell me what this is, or how made? (3) In a negative that has been developed with too small a proportion of ammonia, or an undeveloped negative after it is fixed, can anything be done in the way of re-developing? (4) Toning Bath.—I make my bath with gold 4gr., soda acetate 2dr., water 20oz., and when I have toned about four sheets, I add the same quantity of gold and soda to the old bath; is this right, or should I only add gold and no soda? (5) After using the bath there is always a black precipitate: it does not affect the bath; should it be filtered out?—P. C. W.

[51693.]—**Chandelier.**—I have recently purchased a good three-light gas chandelier which was very dirty. I washed it in a hot solution of soap and soda, which has much improved it; but it is greatly tarnished with black spots. How can I remove them? Is it usual to have them relacquered or burnished?—Chandelier.

[51694.]—**Lawn Tennis Court.**—At a place that I have recently purchased I find a lawn tennis court, which the former owner has laid with stones and concrete to the depth of about 4in., but at present it is too rough for playing on. What is the best and cheapest material to put a smooth coating over the concrete, and which will resist wet and frost? I have asked one of the asphalte companies, but £100 would not do it, and this is out of the question?—H. B.

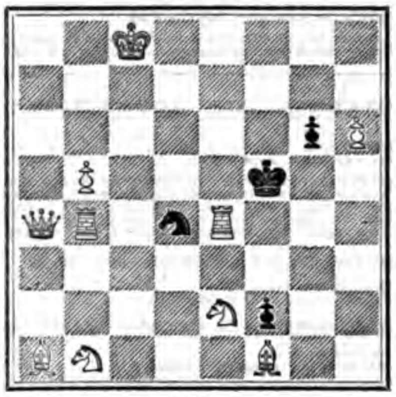
Ensilage Experiment.—Mr. T. H. Miller, of Singleton-park, near Preston, thinks the "silo" for the preservation of green crops need not be a pit or excavation; and he has conducted to a successful issue on the Home Farm, Singleton, an experiment of the greatest interest to agriculturists. He made use of an old cart-house, above which was a granary, the flooring of which he had cut away, with the exception of a portion at one end to serve as a platform. The walls of the building were lined with cement to a height of eight feet, and when this was set the filling of the silo began. Between the 25th of June and the end of August there were placed in it, at irregular intervals, 15 tons of meadow grass in a wet condition, 15 tons 4cwt. of rye grass and clover, and 4 tons 15cwt. of green oats in full head, chopped into 3in. lengths; total 34 tons 19cwt., the produce of seven acres. The mass was kept covered with slotted boards, and weighted with 200 bags containing 126lb. of sand each. These were manipulated easily by means of a rope and pulley, worked from the platform. On the 27th ult. there was no heat or brewing, and but the very slightest perceptible warmth. A portion of the ensilage taken from a depth of 37in., was of a yellowish brown, and moist, but perfectly sweet. A bullock ate some of it greedily, and a handful put in some hay was eaten by a cow before she would touch the hay. The silo is to be formally opened in November in the presence of a number of farmers and friends.

CHESS.

All Communications for this department must be addressed to J. Pierce, Bryn Rhedyn, Llandwrog, Carnarvon.

PROBLEM DCCCLII.—"Sub Judice."

Black.



White. [10+4

White to play and mate in three moves.

Solution to 850.

White.	*Black.*
1. Kt-Q B 5	1. P takes Kt (a)
2. Q-K B 4	2. Anything
3. Q, R or Kt mates.	
	(a) 1. Kt takes Kt (b)
2. R takes P (ch)	2. Anything
3. Q mates	
	(b) 1. B takes R (c)
2. Q takes B (ch)	2. K takes Kt
3. Q mates	
	(c) 1. B-K sq, &c.
2. R-Q 4 (double ch)	2. K takes Kt
3. Q mates	

NOTICES TO CORRESPONDENTS.

Correct Solutions to 849 by C. Planck (a good two-mover, sound and totally free from duals), A. E. S. (very fair); to 850 by C. Planck (a very fine and beautiful stratagem) and A. E. S. (with a better first move this would be charming, and perhaps the best of the three-movers); to 851 by Mortimer and C. Planck (neat and well constructed).

R. A. B.—There is no mate your way to 850 if after

$$1.\ \frac{\qquad}{\text{B-K sq (ch)}}\quad 2.\ \frac{\text{K-K 7}}{\text{K-B 3}}.$$

G. H. M. and J. C.—Game received with thanks.

B. G. L.—Thanks for letter.

English Mechanic Tourney game between Mr. Jowett (*White*) and Mr. Vincent (*Black*).

(Scotch Gambit.)

1. P-K 4, P-K 4 2. Kt-K B 3, Kt-Q B 3 / 3. P-Q 4, P takes P / 4. B-Q B 4 (*a*), B-B 4 (*b*) / 5. Kt-Kt 5 (*c*), Kt-R 3 / 6. Kt takes B P, Kt takes Kt / 7. B takes Kt (ch), K takes B / 8. Q-R 5 (ch), P-Kt 3 / 9. Q takes B (*d*), P-Q 4 / 10. Castles (*e*), P takes P / 11. B-Kt 5 (*f*), Q-Q 3 / 12. Q-B 4 (ch), B-K 3 / 13. Q-K 2 (*g*), Q-B 4 / 14. Q Q 2, K-K sq (*h*) / 15. B-R 6, R-K Kt sq (*i*) / 16. P-K R 4, Kt-K 2 / 17. P-Q R 3, Kt-B 4 / 18. R-K sq, B-Q 4 / 19. Q-K B 4, K-Q 2 (*k*) / 20. Kt-Q 2, Q R-K sq / 21. P-Q Kt 4, Q-B 6 (*l*) / 22. Q-Q 3, Q takes Q / 30. P takes Q, R-Kt 5 / 31. Kt-R 2, R takes P (ch) / 32. K-R sq, R takes Kt (ch) / 33. K takes R, Kt-B 6 (ch) (*p*) / 34. Resigns.

Notes.

(*a*) Kt takes P is considered to lead to a stronger attack.
(*b*) P-Q 3 may also be played with advantage.
(*c*) Bad.
(*d*) Q should first check at Q 5.
(*e*) Q takes P is inferior.
(*f*) Gossip gives here $\frac{\text{P-Q B 3}}{\text{B-K B 4}}$. The text move seems to play Black's game.
(*g*) The position indicates that White's fourth move is weak, as his opponent has now gained a P; his pieces are well out with two centre pawns to the front.
(*h*) We prefer K R-K sq as more attacking.
(*i*) To allow the Kt to be moved to assail the strongly placed B: also with a view to playing P-K Kt 4.
(*k*) Evidently Q cannot take Q B P.
(*l*) A good move.
(*m*) We should prefer Kt-B sq.
(*n*) Now for the tug of war
(*o*) Nothing better: he may now cry "peccavi."
(*p*) A neat finish.

A luminous waterproof paper, the *Papierzeitung* says, may be made from a mixture 40 parts pulp, 10 parts phosphorescent powder, 1 of gelatine, 1 potassium bichromate, and 10 parts of water.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* Editor *of the* English Mechanic, 31, *Tavistock-street, Covent Garden, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

A NEW VOLUME.

This number is the second of Volume XXXVIII. Readers willing to oblige us by recommending "ours" to new subscribers should do so now, when a new volume is commencing. The index to Vol. XXXVII. will be published next week, and cases and bound volumes will be on sale shortly after. Readers desirous of making up their sets for binding the past volume are recommended to do so at once, as the back numbers soon run out of print.

The following are the initials, &c., of letters to hand up to Wednesday evening, Sept. 12, and unacknowledged elsewhere:—

H. Ash.—W. Kitney.—C. Birchall.—Rev. J. Rawlins.—R. E. Quinn.—Col. Fendall.—R. Irvine.—L. Ames.—G. Kidd.—Rev. H. Harries.—South London Machinists' Co.—G. Legge.—Garnet.—Old Subscriber.—Tyro.—Wm. Cowan.—E. M. H.—Neglected Education.—Imprimatur.—G. Roberts—R. W. A.—Nonplus.—J. E. Spencer.—Shepherd.—Keraulophon.—W. F. Love.—Fred.—V. M.—C. Gravenhall.—Orderic Vital.—J. E. A.—G. Minor.—Amateur.—Carboniferous.—K. S. T.—Luminous.—F. W. Brewer.

Garnet. (Is not the question sufficiently answered in recent replies? Much depends on the pupil. Try what you can do.)—A. B. (The firing composition is always nitre and gum; but the odour is imparted by cascarilla, benzoin, styrax, cloves, vanilla, balsam of tolu, and many other substances. Here is one recipe: Benzoin 4oz., cascarilla ½oz., nitre and gum arabic of each 3 drachms, myrrh 1 dr., oils of nutmeg and cloves 25 drops of each, charcoal 7oz., all in fine powder. Mix with water to a smooth, stiff paste, and mould to shape desired. The quantities of charcoal and nitre can be increased to make inferior or less powerfully-scented sticks.)—E. R. Dale. (Cannot say from your sketch and description; but most likely it is for altering the travel of valve.)—A. R. (To the chief engineer or the master, unless you have influence with owners. Try Ainsley's Manual, published by the author at South Shields.)—B. (The contrary way. What textbooks have you looked into? Most of them contain the diagrams you want.)—W. Netting. (Yes, it is the cheapest; but it will take about 20 cells.)—Paste. (Twist the ends together and electroplate them. See p. 425, last volume.)—W. C. (For nickel-plating, see Nos. 808, 811.)—Harmonium Stops. (You will find a diagram in Vol. XXI., p. 330; but the number is out of print. You must give some idea of the construction of your instrument, as most likely it cannot be put in.)—J. W. Horton. (See p. 336, No. 872. Enough wire should be wound on to make the coil three times the diameter of the core. 2. There are so many that we must refer you to the indices. We know of none for the new subject. 3. Depends on circumstances. Some have lasted, we believe, for 3,000 hours. The Bunsen; but Trouvé's bichromate is probably the most agreeable. The other question is answered by the advertisements.)—Photog. (All you have to do is to get some positive collodion.)—H. A. O. (See pp. 198, 223, Vol. XXVII., and the indices.)—Van Tromp. (Yes, by lantern and slides.)—J. H. D. A. (See list of Back Numbers in this column last week.)—Black Beetle. (Powdered borax is said to be an efficient remedy. See pp. 391, 517, 569, 596, Vol. XXIII. It is placed in all their haunts and stuffed into the holes from which they emerge. It may be mixed with meal or sugar.)—Edward Johnson. (From the Queen's printers, East Harding-street, E.C. Not more than a few pence. 2. Very good.)—Marine Engineer. (See p. 100, No. 836, and obtain Ainsley's Guide from the author, South Shields. See answer to "G. W. R." in the number for August 31.)—Barometer. (Take the height of the mercury in the short leg as a base line for measuring that in the long leg; but why use a bent tube at all?) High Peak. (You have simply not followed the directions, which are very clear and explicit. Instead of having all the cells in one series, you have made each row a series. Start at one end, and couple all the cells, so that you have only two terminals, and try again. The solution will destroy the zincs quite quick enough, without being made stronger.)—H. Hagensen. (Could be, of course: but what good would they be? It would cost much more work to wind them up than they would give out, and the fall is too little. Besides, you would want about a ton to do anything at all.)—W. J. B. (An almost identical query was inserted on p. 539, No. 959, and was replied to on pp. 551, 561, last volume.)—Tilbury. (Yes; but the Lord Chancellor has special powers. We suspect you would have to obtain a special Act of Parliament, and prove that the payment was omitted by inadvertence. You could obtain patents in foreign countries;

[illegible] will be very [illegible] that the English [illegible] is published [illegible] the formulæ explained [illegible] —E. S. [illegible] was illustrated and [illegible] XXXV. —[illegible] in the first [illegible] is to regulate the amount of fees [illegible] the Act extends to all patents [illegible] of applications [illegible] a physician. Read an [illegible] —A Con- [illegible] were [illegible] Most of them can be found [illegible] must be scraped [illegible] by the remedies [illegible] are made in a variety of ways [illegible] the draught. [illegible] the steam can [illegible] will not need an outlet to [illegible] of those which is [illegible] you must have an [illegible] say where that should be [illegible] the boiler and the pipes.— [illegible] a reference to the page, [illegible] what you wish to do, or [illegible] You [illegible] chemicals—not druggists. Yes; 2 Yes; 3, Doubtful. [illegible] always be given. Are you quite [illegible] a yearly tenant? Perhaps you [illegible] by consulting a solicitor before fight- [illegible]

USEFUL AND SCIENTIFIC NOTES.

◆

The Fossil Footprints in Nevada.—Much [illegible] in American scientific circles [illegible] supposed human footprints dis[illegible] in the yard of the Nevada [illegible]. Dr. Harkness, of the [illegible] Academy of Sciences, has affirmed that [illegible] were made by a race of big-footed [illegible] O. C. Marsh, of Yale, combats [illegible] The footprints are in six series, each with [illegible] right and left tracks, the stride being [illegible] in extent. The individual foot[illegible] to 20in. over in length and about [illegible] The distance between the line of the [illegible] and left-hand tracks, or the straddle, is [illegible] Professor Marsh considers that the [illegible] footprints, and especially the width [illegible] right and left series, is strong evidence [illegible] were not made by men. He believes a [illegible] explanation is that the impressions [illegible] tracks of a large sloth, either mylodon or [illegible], remains of which have been found in [illegible] the same horizon. The footprints are [illegible] exactly what these animals would make if [illegible] feet covered the impressions of those in [illegible] The size, stride, and width between the [illegible] series of impressions all point to the [illegible] the mylodon or morotherium might [illegible] to make. Since expressing these views [illegible] National Academy of Sciences Professor [illegible] photographs and casts of the [illegible] and has been confirmed in his opinion [illegible] human tracks were made by [illegible] toothless animals, to which the [illegible] armadillo belong. The important [illegible] that some of the tracks [illegible] of the forefoot; and the latter are [illegible] of the large footprints, as would [illegible] if the animal changed its [illegible]

[illegible] in the Southern States, in operation [illegible] cotton factories. This [illegible] all the cotton factories in New [illegible] of Massachusetts, and exceeds by [illegible] State. The figures speak for [illegible] an outline of what the South [illegible] of becoming her own producer, [illegible] and consumer.

Every Workman connected with the Building Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at [illegible], Tavistock-street, Covent-garden, London, W.C.

"THE BUILDING NEWS" is the Principal Journal, representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is One Shilling for Twenty-four Words, and Sixpence for every Eight Words after.

CHARGES FOR ADVERTISING.

	s.	d.
Thirty Words	2	6
Every additional eight words	0	6

Front Page Advertisements Five Shillings for the first 40 words, afterwards 9d. per line. Paragraph Advertisements One Shilling per line. No front page or paragraph advertisement inserted for less than Five Shillings. Reduced terms for series of more than 6 insertions may be ascertained on application to the Publisher.

ADVERTISEMENTS in EXCHANGE COLUMN—for

Twenty-four words	0	3
For every succeeding Eight words	0	3

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

	s.	d.
Sixteen words	0	6
For every succeeding Eight Words	0	6

⁂ It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.

The address is included as part of the advertisement, and charged for.

Advertisements *must* reach the office by 1 p.m. on Wednesday to insure insertion in the following Friday's number.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

6s. 6d. for Six Months and 11s. for Twelve Months, Post-free to any part of the United Kingdom. For the United States, 13s., or 3 dols. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 6d. each to cover extra postage.

Messrs. JAMES W. QUEEN and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post-free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 6d. each copy, to cover extra postage.

Vols. XXIV., XXVI., XXVII., XXVIII., XXX., XXXI., XXXII., XXXIII., XXXIV., XXXV., and XXXVI., bound in cloth, 7s. each. Post free, 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in March and September, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post-free from the office (except index numbers, which are 3d. each, or post-free, 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI. and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

Holloway's Pills have many competitors, though no equals, for supplying the young and delicate with a simple, strengthening, and purifying aperient. These Pills, composed of the finest balsams, are particularly adapted for all complaints peculiar to females, and are most serviceable at the critical periods of early and mature years.

OUR EXCHANGE COLUMN.

◆

The charge for Exchange Notices is 3d. for the first 24 words, and 3d. for every succeeding 8 words.

◆

Wanted, all kinds of useful **Apparatus**, in exchange for offers or cash.—CAPLATZI, Science Depot, Chenies-street, Tottenham-court-road.

"**English Mechanics**," volumes or odd numbers looked out for specialities. Will exchange for lathe appliances or scientific apparatus. Stamp. — LINSCOTT, Addington-street, Ramsgate.

Quarter-horse Horizontal, Slide-valve, high pressure ENGINE, made to scale, perfect, Ariel governors; magnificent; under massive glass case, gold and electro-plated. Cost £65. Exchange.—Mr. SEEL, F.R.H.S., Stalybridge.

44in. Meteor **Tricycle**, splendid condition; in exchange for American Organ, or small screw-cutting Lathe.—H. W., 4, St. Aubin Villas, Crescent, Stamford-hill, N.

Gas Engine and Lathe wanted. Can give Photographic Apparatus, Tricycle, Chemicals, Gun, Engine Castings, many other things.—Apply, with offers, through WILLIAM BRADSHAW, Enniskillen.

Bicycle, 53in., ball bearings to both wheels, ball pedals, hollow front and back forks, bent handle bar, all bright, little worse than new, cost £20; will exchange for a strong 5in. centre (or thereabouts) screw-cutting lathe.—J. C. P. HAWKS, Bank Top, Gateshead-on-Tyne.

Large pair of **Steelyards**, to weigh 18cwt., little worn, by Avery. Take good exchange. Approval.—D., care 310, Bilston-road, Wolverhampton.

Anglo-German **Concertina**, 20 keys, screwed notes, cost 9s; and achromatic pocket Telescope, two eyepieces and sun-glass, for Violoncello, Metronome, &c.; Amateur Organ or offers.—L., 29, St. Augustine's-road, N.W.

Wanted, part of **Shaping** or Similar Machine, capable of right and left traverse 9 to 12in., and to rise and fall. It is to place on table under circular cutter already mounted on spindle.—J. V. R., 39, Lower Sackville-street, Dublin.

Tricycle.—Ironwork fitted ready for wheels, works hands and feet; for rubber tires, workman's watch, or offers.—A. W., 16, West-street, Maryland Point.

Gun-metal **Slide-Rest**, suit 4½ or 5in. lathe. Exchange lathe, engine, photo. apparatus, *Design and Work*, tools, or offers.—GIBSON, 348, Nursery Cottages, High-street, Gateshead.

Half Horse-Power Horizontal **Engine**, turned fly and driving wheels, on iron bed, &c. What offers?—W. ALGAR, Stonard-road, Winchmore-hill, London, N.

Electrical.—12in. Plate-glass Machine, on polished mahogany stand, discharging rod, Leyden jar, electro-magnet, handsome saloon pistol, &c. Wanted, good slide-valve engine, 1¼ to 2in. bore.—R. W., 51, Courthill-road, Lewisham.

Magic Lantern, three inch condenser, focussing tube, lamp, 5ft picture, complete, cost 25s. What offers?—JEFFERIES, 3, Gipsy Villas, Gipsy-road, Lower Norwood.

One or two Three Guinea full-sized **Frock Coats**, very little worn, exchanged for portable telescope; good twenty miles.—H., 27, Fearnlea-road, Balham, Surrey.

Vols. I., II., III., "**Knowledge**," unbound; Vols. XIII., XIV., ENGLISH MECHANIC, bound; Darwin's "Origin of Species;" for Theobald's No 3 Combination Telescope, complete.—B., 147, Farringdon-road Buildings, London.

Camera, with telescopic mahogany body, 9in. by 8in., stereoscopic front, splendid lens, with rackwork, dark slides, &c. Exchange.—THOS. LISLE, Villiers-street, Wolverhampton.

Microscopic.—Anther Malope Grandiflora, beautifully mounted on opal or ordinary slide. Exchange.—KILGOUR, 63, Dallfield-walk, Dundee, N.B.

Splendid **Flutina**, by Busson. Will exchange for good violin and bow, or Anglo steel-reed Concertina. Also for exchange, small battery and coil.—H. WEBB, Bootmaker, 1, Bell-street, Wolverhampton.

"**Knowledge**," "Amateur Work," "Universal Instructor," "Public Opinion" (from 1881), all complete to date, with indices, clean and perfect; cost 65s. Musical exchange wanted, or offers.—H., 2, Rose-street, Cornbrook, Manchester.

Emery Wheel, 2ft. by 3in., a rapid fitter; quantity of Marble Letters, suit builder; enough for the following words:—Carpenter, Builder, and Undertaker. One Leaden Generator and Vat.—10, Pitlake-bridge, Croydon.

Wanted, Sociable **Tricycle**, good make, any condition; exchange Bicycles in perfect condition.—W., 89, Maxey road, Plumstead.

Good English eight-day striking **Clock**, in long oak case, 54in. Bicycle, and a capital Treadle Sewing Machine; exchange Photographic Apparatus, or offers.—A. GARDNER, Towcester.

Fifty numbers "**English Mechanic**," from 235 to 537; also several indices, and Volume XVI., complete, unbound. Exchange.—H. HAWKINS, Hinton, Martock, Somerset.

Wanted to exchange, first-rate **Violin**, bow and case, for good Photographic Apparatus, complete.—G. LEGGE, Aylesbury.

THE SIXPENNY SALE COLUMN.

◆

Advertisements are inserted in this column at the rate of 6d. for the first 16 words, and 6d. for every succeeding 8 words.

◆

Bicycles, Tricycles, Wheels, and parts, and frames complete.—W. GWINNETT, AND Co., Wednesfield-road, Wolverhampton.

Electrical Depot and Manufactory.—Handiest shop in the trade for amateurs.—MILLAR'S, 126, Chapel-street, Salford.

Motor Castings, materials for Electric Bells, Batteries, Galvanometers, Intensity Coils, Microphones, Terminals.—KING and Co., Bristol.

Wimshurst Influence Machine; complete; with two Leyden jars, £3 10s., 4½in. spark.—Makers, KING and Co., Bristol.

Wimshurst Influence Machine, sole manufacturers; high-class workmanship; numerous testimonials as to thorough efficiency.—KING and Co., Bristol.

Violin, the Collin-Mezin Violin (the finest new violin made). Approval allowed.—Importer, ALPHONSE CARY, Newbury.

Violins, by Signor Verini, splendid tone; price 5 guineas. Trial allowed.—Sole Importer, ALPHONSE CARY, Newbury.

Violins, splendid copies of old masters, 28s., 36s., 47s., and upwards. Approval allowed.—ALPHONSE CARY, Newbury.

Violin Strings (finest Italian imported), very durable. Three Firsts free for 13 stamps.—ALPHONSE CARY Newbury.

Pyrotechnic and Trade Chemicals.—Lowest price at GAUBERT and KELLY'S (late Page), 47, Blackfriars-road.

10,000 Artistic **Photographs**. Popular celebrities Actresses, Celebrated Paintings, Antique and Modern Sculpture, Classic Studies for Artists, &c. Unrivalled collection. Packets are sent for selection, post free. Catalogue and specimens, 6d.—T. WILLIAMS and Co., Photographic Publishers (P 13), Bridgnorth. Agents wanted.

Turned wrought-iron **Pulleys**, not polished on a grindstone like those generally sold. Cheap, strong, true.—BAGSHAW and SONS, Batley.

Friction Pulleys dispense with fast and loose pulleys—one answers for both. Invaluable for ropes and belts. Illustrated circular free.—BAGSHAW and SONS, Batley.

Microscopic. — The beautiful building Rotifer, Melicerta Ringens. Large healthy specimens, tube, 9d.—[illegible], Ayr, Scotland.

£2 7s. 6d. for **Square Piano**, in good order, sweet tone.—TERRILL, 2, Tottenham-street, London, W.

Electric Bell, Indicators, Batteries, Wire, Carbons, and Sundries, &c. List one stamp.—E. CRICK, 9, St. James's-walk, E.C.

Steam Launch, 30 feet by 6, fast, nearly new, price £130.—Dr. DIXON, Stockton-on-Tees.

in *use* up to date. His 78 pages of letterpress contain much original matter; we should be glad to see the pamphlet doubled in bulk, still preserving the character of practical notes.

THE CULTIVATION OF SORGHUM.

THE cultivation of sorghum is just now attracting considerable attention in the United States, and it so happens that it is a question of some interest to many in this country; for if it should prove to be profitable, many capitalists will invest their money in land in the Far West, many of the corn growers already located there will grow sorghum, and there will be less wheat to export. Until very recent times a crop of sorghum had no very definite value; for, although the great millet is a staple article of food all over Asia, Africa, and part of Europe, the stalks forming good fodder for cattle, the fruit has not been considered as a valuable cereal in the United States. Sorghum vulgare, however, possesses a saccharine juice, which it has been comparatively recently discovered can be converted into sugar—that is, the sucrose of the sugar-cane, Saccharum officinarum. Sorghum has always been grown in parts of the United States for the syrup it yielded, and for fodder, while the seed or grain was used for feeding pigs, poultry, &c.; now that a method of making sugar from it has been laid down in all its details, there will probably be an enormous increase in the area devoted to its cultivation, for the simple reason that the United States consumes annually about 2,000 million pounds of sugar, nine-tenths of which is imported. It must be remembered that the sugar cane itself grows to perfection scarcely anywhere in the States, though, in Louisiana it is the staple and probably most profitable crop; but the Sorghum can and does flourish as far north as Dakota, and will reach perfection in all the States lying in the centre of North America. That it has not hitherto been cultivated as a sugar-yielding plant is due to the fact that the production of sugar from the juice could never be relied upon: sometimes the sugar would crystallise out beautifully, at others the juice obstinately remained as syrup. The difference between sorghum and saccharum juice is just that which is understood by glucose and sucrose, or grape sugar and cane sugar; but it was known for some years that the juice obtained from sorghum contained sucrose, though it was only occasionally and, as it were, by accident, it could be induced to crystallise out of the syrup. Accordingly, the question was taken up by the United States Department of Agriculture, and a series of elaborate analyses of sorghum were made at various stages during the growth of the plant. It was then found that in the latter part of July the sorghum juice contains more glucose than sucrose; but from the beginning of August the quantity of sucrose increases rapidly until the seeds begin to harden, when the increase is checked, and when the seeds are fully ripe the sucrose has reached its maximum, which is equal according to locality and variety of the sorghum to the percentage of sugar obtained from the sugar-cane. In some localities and with some varieties sorghum gives a greater yield than saccharum, and in the South of Russia, where experiments have been made with it lately, the yield has been from nine to fourteen per cent. While the sucrose increases in the sorghum plant the glucose decreases, and the object of the cultivator is to cut his crop at the time when the sucrose is at a maximum and the glucose at a minimum. He has often done that, and yet failed to obtain sugar. The reason has been found in the fact that sorghum juice, unlike that of the sugar-cane, is remarkably unstable, and has a perverse tendency to change all its sucrose into glucose within a very short time. The cause of the failure to obtain sugar being known, the remedy was easily found, and that is to boil the juice as soon as the plant is cut. The transformation can, it is stated, be prevented by the use of lime; but practically the sugar will, in future, be secured by prompt boiling of the juice as fast as it is obtained from the recently-cut plants. In the light of knowledge, it is easy to explain why sorghum juice was found so capricious, at one time yielding beautifully crystallised sugar, and at another (most frequently) only nice syrup. It may be safely predicted that before long the United States will produce all the sugar required by its inhabitants, and that the great millet will be cultivated in Africa and Asia and parts of Southern Europe for its sugar as much as for its seeds.

PRESERVING FRESH MEAT.

A METHOD of preserving fresh meat by means of a mixture of carbonic oxide and carbonic acid in certain proportions, has been recently patented by Mr. C. M. Pielsticker, of Sidney-terrace, Kilburn. Carbonic oxide, as is well-known, is highly inflammable, and mixed with atmospheric air in certain proportions is explosive. Carbonic acid gas by itself discolours the fresh meat fibre, and causes the meat to assume an acid taste. By using a mixture of carbonic acid and carbonic oxide in certain definite proportions (say not less than 55 per cent., nor more than 75 per cent. of carbonic acid gas, to not more than 45 per cent., nor less than 25 per cent. of carbonic oxide gas, in which the presence of any nitrogen gas is immaterial), the meat is neither changed in the slightest degree in appearance or taste, nor is it at all possible to set fire to the mixture of gases, it being a well-known fact that no flame or fire can exist in the presence of carbonic acid gas, even if united with three times its volume of atmospheric air. The mixture of gases is produced by means of an apparatus forming part of the invention, which is constructed in the following manner:—

An iron, or other suitable cylinder, say 2ft. high and 8in. diameter, or larger in these proportions, is furnished at the bottom with ordinary grate bars. About 2in. above the grate is an inch hole in the side of the cylinder for the admission of a forced air blast by means of a pair of bellows or otherwise. Near the top of the cylinder a number of 1in. pipes enter all round circumference and project about 2in. inside the cylinder for the admission of air into the upper part of the cylinder. The number of these air pipes is in the proportion of one to every 2in. of diameter of the cylinder, so that for instance a cylinder of 8in. diameter requires not less than four air pipes, which in practice give the correct proportion of carbonic acid and carbonic oxide gas. The cylinder is closed at the top with an iron cap, having an outlet pipe say 2in. in diameter and 2ft. or more in length; it is connected with an iron coil placed in a water tank and kept cool by the circulation of cold water. The lower end or outlet of the coil is connected with the preserving chamber. In order to produce the mixture of gases, the patentee fills the cylinder with wood or mineral charcoal, and having ignited it, applies a blast through the hole left for that purpose in order to promote combustion. The gas which arises consists mainly of carbonic oxide gas mixed with some carbonic acid gas and also nitrogen gas, which latter need not be considered. In the upper part of the cylinder the carbonic oxide is further partly oxidised into carbonic acid gas by the further supply of atmospheric air. When the number of 1in. air pipes is in the proportion of one to every two inches of the diameter of the cylinder, the mixture of gases is in correct proportion to each other, and they neither change the taste and appearance of the meat nor are in the slightest degree inflammable. The gases pass through the coil, where they are cooled, into the preserving chamber, with which the lower outlet of the coil has previously been connected. The mixture of gases may be passed into and through the preserving chambers continually during the voyage of a steamer, or the air in the preserving chambers may be merely removed, the chambers well filled with the mixture of gases and then both inlet and outlet closed, or the gases may be again exhausted after treatment, and a partial vacuum left in the chambers. The mixture of gases may be either used by itself, or as an after treatment following the use of any antiseptic.

ZINC FOR PREVENTING BOILER CORROSION.

THE use of zinc for preventing corrosion in steam boilers has formed the subject of several patents, and recently Mr. J. B. Hannay, of Glasgow, has obtained a patent for further improvements on his invention of 1881. According to the present invention the zinc masses of spherical, or spheroidal, or polyhedral, or cubical form, or other form having small difference of thickness in different directions, are rendered more durable and efficient by being brought into the condition known as malleable, instead of being used in the condition they have when simply cast. For this purpose the masses are hammered or forcibly pressed or rolled, the operation being by preference effected suddenly. Thus a convenient and satisfactory means for the purpose consists of a powerful screw press fitted with a heavy flywheel or heavily weighted arms and provided with suitably shaped dies. By a further improvement the zinc is made more susceptible of being rendered malleable by being alloyed with a small portion, say, not more than 10 per cent. of lead, tin, or copper. Another improvement consists in carrying each of the zinc masses in the boiler in an iron ladle of suitable size, such ladle being clamped to some of the tubes or fixed inside the boiler in any convenient way, and not requiring to be removed when supplying new blocks or balls of zinc, as such blocks or balls have simply to be placed in the ladles after those have been cleared out.

The patentee claims as novel and original—1. The use of zinc blocks or masses of a spherical, or spheroidal, or polyhedral or cubical or other similar form for preventing corrosion in steam boilers, such blocks or masses having been subjected to compression after having been cast. 2. The forming of the blocks or masses of zinc alloyed with 10 per cent. or less of lead, tin, or copper, and subjected to compression after having been cast.

PATTERN MAKING.—XV.

Strap Pulleys (*continued*).

THE arms of pulleys, or of riggers (Fig. 71) as they are sometimes called, are usually curved, except in the case of those of very small diameter. This curving is considered essential in these light castings, lest the shrinkage of the boss which remains hot longest should tear the too rigid arms asunder, either in the mould or at some subsequent period. Straight arms would be unyielding, while curved ones are somewhat analogous to a bent spring. For the same reason, also, the greatest care is necessary in properly proportioning the metal in the different parts—boss, arms, and rim. To reduce the metal in the boss is the great essential. A heavy boss will infallibly break either the arm or the rim. If the rim is very rigid, the arm will break, while, if the arm be too strong the rim will break. In either case, the mischief is due to the internal tension or stress set up through the contraction of the boss continuing after the rim and arms have cooled down and set. Hence, let the pulley be so proportioned that the boss shall contract very little after the other parts have cooled—so little that the moulder can counteract that small excess by opening the mould around the boss and allowing it to cool while the rim and arms still remain covered. Make the boss as light as possible consistently with safe working, and give the necessary strength for keying, by adding a keyway boss (Fig. 71.)

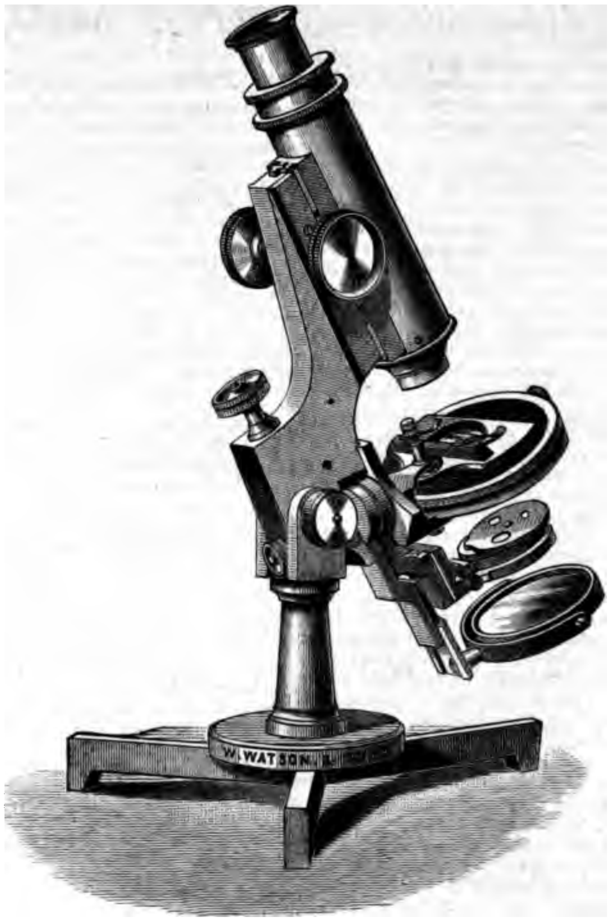
To proportion pulleys. Let the rim be from $\frac{3}{16}$in. thick in small riggers to $\frac{1}{4}$in. or $\frac{5}{16}$in. in large ones. For pulleys running at a high speed give an $\frac{1}{8}$in., or $\frac{3}{16}$in. rounding per foot wide of surface; for those running at slow speeds, say, $\frac{3}{8}$in. of rounding per foot. This rounding must be omitted in the pattern, except where it happens to be parted in the centre, care being taken, however, to allow sufficient thickness of rim to permit of the casting being turned to this extent in the machine shop.

For the curves of the pulley arms set rules could be given; but, for my part, I never use then, preferring simply to line out roughly with pencil an arm which has a graceful appearance, and then adapt radii to it. In giving to the arms their *cross sections* a trained eye is almost as good as rules; but in the absence of experience, the following rule gives correct results for pulleys doing ordinary work.

$$\sqrt[3]{b} = \frac{d \times w}{n \times 8}$$

where b = breadth of arm at point.
d = diam. of pulley in inches.
w = breadth of rim in inches.
n = number of arms.

Thus, a pulley 4ft. in diameter by 9in. wide, having six arms, would have an arm 2in. wide at the point. Near the boss the arm should be one-third wider than it is at the rim. Its section



which is pressed against the lever by a strong spiral spring. It is claimed for this system of fine adjustment that there is less lateral rocking than in the Zentmayer system. The stage is circular; it can be rotated completely, and centring screws are provided, by which it can be made to rotate exactly on the optic axis. The "Tighlmann" friction movements carry the object, and a simple mechanism enables the operator to remove the stage-plate and substitute a glass stage for chemical reactions, &c. Two tail-pieces are provided, one carrying the sub-stage, the other the mirror; they swing laterally, either together or independently, on the same axis, the suspension being arranged as in the Zentmayer form, so that the movement is radial with the object, and in the plane of the optic axis. The substage is of the standard gauge (1½in.), and ordinarily carries a conical diaphragm. A condenser can, of course, be substituted.

On the whole this little microscope appears to be a good working model, and we think Messrs. Watson deserve credit for introducing it to this country at a price which will enable it to compete favourably with the American microscope on which it is based. We understand that the Editor of the *Journal* of the Royal Microscopical Society has commended this form as one of the best student's microscopes yet issued.

We would suggest to Messrs. Watson the advisability of applying a clamp-screw to the tail-pieces so that they may be fixed rigidly in the normal position when axial light is being used. We also think it would facilitate the manipulations of the substage and mirror if the pillar support were taller so as to permit the tailpieces to be longer. At present the tailpieces are so short that there is some difficulty in adjusting the illumination beneath the stage, especially when the microscope is vertical.

THE DIALYTE TELESCOPE.

By W. Bradbury.

IT may not be unserviceable to those who wish to take up this kind of telescope, if I give a précis of the accounts of several instruments which have been successfully made on this plan. I am enabled to do this by the kindness of "J. C. L.," who has sent me several odd leaves of early volumes of this journal where these descriptions appear. I shall purposely avoid all theory as much as possible, because I believe more can be done with this construction by following a good model, than by bothering with calculations, which at best can only be a guide, and very likely less to be depended on than the model. In the ordinary object-glass, definition is obtained by adjusting the *faces* of the lenses, but in the dialyte it is got by altering their *places*. Hence, no very exact arrangement of surfaces is necessary, because the final result will depend on how the various elements can be correlated; and this no theory can determine.

I commence with an account furnished by "Hyperion" on p. 586, No. 311. This relates to a dialyte made by Mr. Wray. I give in Fig. 1 a diagram of the lenticular arrangement.

Density of crown glass = 2·50 : of flint = 3·65.

8¼in. equiconvex object-lens, radius 130, focus 120.

4½in. correctors, consist of:—

Double convex crown lens, radii 130 and 12·5.

Meniscus flint lens, radii 12·5 and 130.

The two 12·5 inner faces in contact and cemented.

"When this corrector was placed in the tube, the combined focal length of the telescope was increased to 11 ft.; but the virtual focus gained by the concave was 13ft.; so that with a focal length of about 11½ft., the same magnifying power was obtained as if that focal length had been 13ft."

"The action of the corrector was to cause achromatism in the front lens of 8¼in. aperture, and so it did (remarks Mr. Wray), for the central pencils of rays; but the oblique pencils were deeply tinged with colour, which required a peculiar form of eyepiece to correct. The correction of achromatism was similar to that in an ordinary object-glass, for even in the centre of the field where it was most perfect, the usual secondary spectrum appeared.

"The main objection, however, to this form of telescope, arose from the great difficulty of keeping the corrector precisely in the axial line of the object-lens, and so preserving the right centring of the lenses, without which accurate definition was impossible. Flexure, too, would show its evil effects in a construction where the component lenses of the objective were separated by so large an interval, much more than if they were in contact.

"In its best action (Mr. Wray observes), the definition on double stars and planets was very fine, so long as the observer kept the object near the centre of the field of view; but if, from the slightest cause, the adjustment of the corrector happened to be shifted, the *telescope was useless.*"

I next come to Mr. Herbert Ingall's plan,

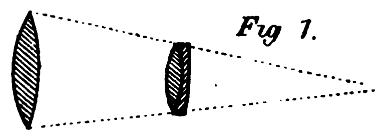


Fig 1.

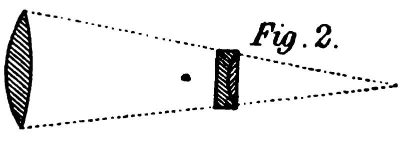

Fig. 2.

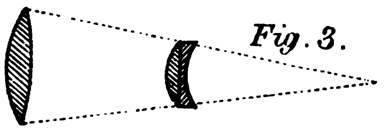

Fig. 3.

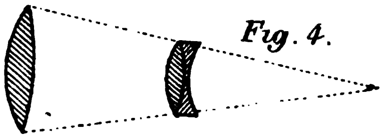

Fig. 4.

described on p. 36, No. 314, and which is shown in Fig. 2.

4½in. object lens, 42in. focus; a crossed lens, radii as 1 : 6.

2¼in Correctors:—

6½in. focus crown lens, "nearly plano-convex, just crossed to avoid having a flat surface, which is uncertain to get correctly."

Flint concave of very dense glass, with curves to match.

The two deeper curves in contact and cemented.

"When this combination was fixed in the telescope-tube with the flint glass towards the object-lens, not only was the colour corrected, but the spherical error was so far diminished as to enable me to 'notch' ζ Boötis, which I did with a power of about 300, in 1865. I perceived, however, that the correctors would correct a much larger diameter lens than the object-glass I then used; so I had another lens worked of exactly the same curves but of larger diameter: but this had some striæ across the centre of the glass, but I saw sufficiently well with this lens to enable me to see that the errors were well balanced. After having two more glasses ground, I got one that was very perfect, and this one I now use in my present instrument.

"My present dialyte has an aperture of 5½in., and the focal length of the instrument is only 5½ft., although from the negative refraction of the corrector, the virtual focus is 96in.—one of the advantages of the construction.

"The telescope is very excellent when in proper adjustment, completely dividing ζ Boötis and notching μ^2 Boötis and ζ Cancri last year with high powers. In fine air, I find great advantage in using a power as high as 772 on the moon.

"The disadvantages of the dialyte are those mentioned by 'Hyperion'—viz., the liability to get out of the centre and the imperfect chromatic correction at the edges of the field, and for this reason I find my telescope appears to perform better with high powers. This colour is perhaps greater in my telescope, as it has what I should call a very exaggerated correction, 5½in. being balanced by a combination of only 2½in. Nothing, however, could be finer than the image of a planet or star in the centre of the field. In fine states of the air, the mottled appearance of the equatorial belt of Jupiter is very beautiful."

Next, on page 524, No. 515, Mr. Ingall says:—"The correction on the dialyte plan can of course be obtained in a great many different ways. The data of my various instruments (being entirely my own from experiment, and accommodation to my available curves) may of course, by no means be the best. In fact, my 5½in., although having such a fine central correction, has a bad *field*, in consequence of the correctors being placed very far back from the object glass." He gives the following data:

4¼in. French plate object-lens, focus 60in., both sides convex, radi 24 and 240 respectively.

I think it may be at once conceded that the truths of geometry are truths precisely because they relate to and express the properties of what Mill calls "purely imaginary objects"; that these objects do not exist, in Mill's sense, that they do not exist in nature, may also be granted; that they are "not even possible," if this means not possible in an existing nature, may also be granted. That we cannot "conceive" them depends on the meaning which we attach to the word conceive. I would myself say that the purely imaginary objects are the only realities, the *ὄντως ὄντα*, in regard to which the corresponding physical objects are as the shadows in the cave; and it is only by means of them that we are able to deny the existence of a corresponding physical object; if there is no conception of straightness, then it is meaningless to deny the existence of a perfectly straight line.

But at any rate the objects of geometrical truth are the so-called imaginary objects of Mill, and the truths of geometry are only true, and *a fortiori* are only necessarily true, in regard to these so-called imaginary objects; and these objects, points, lines, circles, &c., in the mathematical sense of the terms, have a likeness to and are represented more or less imperfectly, and from a geometer's point of view no matter how imperfectly, by corresponding physical points, lines, circles, &c.

Mathematical Theories.

In arithmetic and algebra, or say in analysis, the numbers of magnitudes which we represent by symbols are in the first instance ordinary (that is, positive) numbers or magnitudes. We have also in analysis and in analytical geometry *negative* magnitudes; there has been in regard to these plenty of philosophical discussion, and I might refer to Kant's paper, "Ueber die negativen Grössen in die Weltweisheit" (1763), but the notion of a negative magnitude has become quite a familiar one, and has extended itself into common phraseology. I may remark that it is used in a very refined manner in bookkeeping by double entry.

But it is far otherwise with the notion which is really the fundamental one (and I cannot too strongly emphasise the assertion) underlying and pervading the whole of modern analysis and geometry, that of imaginary magnitude in analysis and of imaginary space (or space as a *locus in quo* or imaginary points and figures) in geometry; I use in each case the word imaginary as including real. This has not been, so far as I am aware, a subject of philosophical discussion or inquiry. As regards the older metaphysical writers this would be quite accounted for by saying that they knew nothing, and were not bound to know anything, about it; but at present, and, considering the prominent position which the notion occupies—say even that the conclusion were that the notion belongs to mere technical mathematics, or has reference to nonentities in regard to which no science is possible, still it seems to me that (as a subject of philosophical discussion) the notion ought not to be thus ignored; it should at least be shown that there is a right to ignore it.

Although in logical order I should perhaps now speak of the notion just referred to, it will be convenient to speak first of some other quasi-geometrical notions; those of more than three-dimensional space, and of non-Euclidian two and three dimensional space, and also of the generalised notion of distance. It is in connection with these that Riemann considered that our notion of space is founded on experience, or rather that it is only by experience that we know that our space is Euclidian space.

It is well known that Euclid's twelfth axiom, even in Playfair's form of it, has been considered as needing demonstration; and that Lobatschewsky constructed a perfectly consistent theory, wherein this axiom was assumed not to hold good, or say a system of non-Euclidian plane geometry. There is a like system of non-Euclidian solid geometry. My own view is that Euclid's twelfth axiom in Playfair's form of it does not need demonstration, but is part of our notion of space, of the physical space of our experience—the space, that is, which we become acquainted with by experience; but which is the representation lying at the foundation of all external experience. Riemann's view before referred to may, I think, be said to be that, having *in intellectu* a more general notion of space (in fact, a notion of non-Euclidian space), we learn by experience that space (the physical space of our experience) is, if not exactly, at least to the highest degree of approximation, Euclidian space.

But suppose the physical space of our experience to be thus only approximately Euclidian space, what is the consequence which follows? Not that the propositions of geometry are only approximately true, but that they remain absolutely true in regard to that Euclidian space which has been so long regarded as being the physical space of our experience.

It is interesting to consider two different ways in which, without any modification at all of our notion of space, we can arrive at a system of non-Euclidian (plane or two-dimensional) geometry; and the doing so will, I think, throw some light on the whole question.

First, imagine the earth a perfectly smooth sphere; understand by a plane the surface of the earth, and by a line the apparently straight line (in fact, an arc of great circle), drawn on the surface; what experience would in the first instance teach would be Euclidian geometry; there would be intersecting lines, which, produced a few miles or so, would seem to go on diverging, and apparently parallel lines which would exhibit no tendency to approach each other; and the inhabitants might very well conceive that they had by experience established the axiom that two straight lines cannot inclose a space, and the axiom as to parallel lines. A more extended experience and more accurate measurements would teach them that the axioms were each of them false; and that any two lines, if produced far enough each way, would meet in two points; they would in fact arrive at a spherical geometry, accurately representing the properties of the two-dimensional space of their experience. But their original Euclidian geometry would not the less be a true system, only it would apply to an ideal space, not the space of their experience.

Secondly, consider an ordinary, indefinitely extended plane; and let us modify only the notion of distance. We measure distance, say, by a yard measure or a foot rule, anything which is short enough to make the fractions of it of no consequence (in mathematical language by an infinitesimal element of length); imagine, then, the length of this rule constantly changing (as it might do by an alteration of temperature), but under the condition that its actual length shall depend only on its situation on the plane and on its direction—viz., if for a given situation and direction it has a certain length, then whenever it comes back to the same situation and direction it must have the same length. The distance along a given straight or curved line between any two points could then be measured in the ordinary manner with this rule, and would have a perfectly determinate value; it could be measured over and over again, and would always be the same: but of course it would be the distance, not in the ordinary acceptation of the term, but in quite a different acceptation. Or in a somewhat different way; if the rate of progress from a given point in a given direction be conceived as depending only on the configuration of the ground, and the distance along a given path between any two points thereof be measured by the time required for traversing it, then in this way also the distance would have a perfectly determinate value; but it would be a distance, not in the ordinary acceptation of the term, but in quite a different acceptation. And corresponding to the new notion of distance, we should have a new non-Euclidian system of plane geometry; all theorems involving the notion of distance would be altered.

We may proceed further. Suppose that as the rule moves away from a fixed central point of the plane it becomes shorter and shorter; if this shortening takes place with sufficient rapidity, it may very well be that a distance, which in the ordinary sense of the word is finite, will, in the new sense, be infinite; no number of repetitions of the length of the ever-shortening rule will be sufficient to cover it. There will be surrounding the central point a certain finite area such that (in the new acceptation of the word distance) each point of the boundary thereof will be at an infinite distance from the central point; the points outside this area you cannot by any means arrive at with your rule. They will form a *terra incognita*, or rather an unknowable land; in mathematical language, an imaginary or impossible space; and the plane space of the theory will be that within the finite area—that is, it will be finite instead of infinite.

We thus, with a proper law of shortening, arrive at a system of non-Euclidian geometry which is essentially that of Lobatschewsky. But in so obtaining it we put out of sight its relation to spherical geometry; the three geometries (spherical, Euclidian, and Lobatschewsky's) should be regarded as members of a system—viz., they are the geometries of a plane (two-dimensional) space of constant positive curvature, zero curvature, and constant negative curvature respectively; or again, they are the plane geometries corresponding to three different notions of distance. In this point of view they are Klein's elliptic, parabolic, and hyperbolic geometries respectively.

Next as regards solid geometry; we can, by a modification of the notion of distance (such as has just been explained in regard to Lobatschewsky's system), pass from our present system to a non-Euclidian system. For the other mode of passing to a non-Euclidian system, it would be necessary to regard our space as a flat three-dimensional space existing in a space of four dimensions (i.e., as the analogue of a plane existing in ordinary space); and to substitute for such flat three-dimensional space a curved three-dimensional space, say of constant positive or negative curvature. In regarding the physical space of our experience as possibly non-Euclidian, Riemann's idea seems to be that of modifying the notion of distance, not that of treating it as a locus in four-dimensional space.

Space of Four Dimensions.

I have just come to speak of four-dimensional space. What meaning do we attach to it? Or can we attach to it any meaning? It may be at once admitted that we cannot conceive of a fourth dimension of space; that space as we conceive of it, and the physical space of our experience, are alike three-dimensional; but we can, I think, conceive of space as being two or even one dimensional; we can imagine rational beings living in a one-dimensional space (a line) or in a two-dimensional space (a surface) and conceiving of space accordingly, and to whom, therefore, a two-dimensional space, or (as the case may be) a three-dimensional space would be as inconceivable as a four-dimensional space is to us. And very curious speculative questions arise. Suppose the one-dimensional space a right line, and that it afterwards becomes a curved line: would there be any indication of the change? Or, if originally a curved line, would there be anything to suggest to them that it was not a right line? Probably not, for a one-dimensional geometry hardly exists. But let the space be two-dimensional, and imagine it originally a plane, and afterwards bent (converted, that is, into some form of developable surface) or converted into a curved surface; or imagine it originally a developable or curved surface. In the former case there should be an indication of the change, for the geometry originally applicable to the space of their experience (our own Euclidian geometry) would cease to be applicable; but the change could not be apprehended by them as a bending or deformation of the plane, for this would imply the notion of a three-dimensional space in which this bending or deformation could take place. In the latter case, their geometry would be that appropriate to the developable or curved surface which is their space—viz., this would be their Euclidian geometry; would they ever have arrived at our own more simple system? But take the case where the two-dimensional space is a plane, and imagine the beings of such a space familiar with our own Euclidian plane geometry: if, a third dimension being still inconceivable by them, they were, by their geometry or otherwise, led to the notion of it, there would be nothing to prevent them from forming a science such as our own science of three-dimensional geometry.

Evidently all the foregoing questions present themselves in regard to ourselves, and to three-dimensional space as we conceive of it, and as the physical space of our experience. And I need hardly say that the first step is the difficulty, and that granting a fourth dimension we may assume as many more dimensions as we please. But whatever answer be given to them, we have, as a branch of mathematics, potentially, if not actually, an analytical geometry of n-dimensional space.

Imaginary Magnitude and Space.

Coming now to the fundamental notion already referred to, that of imaginary magnitude in analysis and imaginary space in geometry; I connect this with two great discoveries in mathematics made in the first half of the seventeenth century, Harriot's representation of an equation in the form $f(x) = 0$, and the consequent notion of the roots of an equation as derived from the linear factors of $f(x)$, (Harriot, 1560-1621; his "Algebra," published after his death, has the date 1631), and Descartes' method of coordinates, as given in the "Géometrie," forming a short supplement to his "Traité de la Méthode, &c." (Leyden, 1637).

There is a well-known construction in perspective for drawing lines through the intersection of two lines, which are so nearly parallel as not to meet within the limits of the sheet of paper. You have two given lines which do not meet, and you draw a third line, which, when the lines are all of them produced, is found to pass through the intersection of the given lines. If instead of lines we have two circular arcs not meeting each other, then we can, by means of these arcs, construct a line; and if on completing the circles it is found that the circles intersect each other in two real points, then it will be found that the line passes through these two points; if the circles appear not to intersect, then the line will appear not to intersect either of the circles. But the geometrical construction being in each case the same, we say that in the second case also the line passes through the two intersections of the circles.

Of course it may be said in reply that the conclusion is a very natural one, provided we assume the existence of imaginary points; and that, this assumption not being made, then, if the circles do not intersect, it is meaningless to assert that the line passes through their points of intersection. The difficulty is not got over by the analytical method before referred to, for this introduces difficulties of its own; is there in a plane a point the co-ordinates of which have given imaginary values? As so arrived at the curves of curvature. (See his "Mémoire sur les Déblais et les Remblais," Mem. de l'Acad., 1781.) The normals of a surface are, again, a particular case of a doubly infinite system of lines, and are so connected with the modern theories of congruences and complexes.

The undulatory theory of light led to Fresnel's wave-surface, a surface of the fourth order, by far the most interesting one which had then presented itself. A geometrical property of this surface, that of having tangent planes each touching it along a plane curve (in fact, a circle), gave to Sir W. R. Hamilton the theory of conical refraction. The wave surface is now regarded in geometry as a particular case of Kummer's quartic surface, with sixteen conical points and sixteen singular tangent planes.

The Extent of Mathematics.

It is difficult to give an idea of the vast extent of modern mathematics. This word "extent" is not the right one; I mean extent crowded with beautiful detail—not an extent of mere uniformity such as an objectless plain, but of a tract of beautiful country seen at first in the distance, but which will bear to be rambled through and studied in every detail of hillside and valley, stream, rock, wood, and flower. But, as for anything else, so for a mathematical theory—beauty can be perceived, but not explained. As for mere extent, I can perhaps best illustrate this by speaking of the dates at which some of the great extensions have been made in several branches of mathematical science.

In conclusion, I would say that mathematics have steadily advanced from the time of the Greek geometers. Nothing is lost or wasted; the achievements of Euclid, Archimedes, and Appollonius are as admirable now as they were in their own days. Descartes' method of co-ordinates is a possession for ever. But mathematics have never been cultivated more zealously and diligently, or with greater success, than in this century—in the last half of it, or at the present time; the advances made have been enormous, the actual field is boundless, the future full of hope. In regard to pure mathematics we may most confidently say:—

Yet I doubt not through the ages one increasing purpose runs,
And the thoughts of men are widened with the process of the suns.

MR. WEBB'S COMPOUND LOCOMOTIVE.

He would, we think (says the *Engineer*), be a rash man who without hesitation condemned the system as thoroughly bad, or praised it as completely good. No one possesses as yet the data necessary to enable a final conclusion to be formed as the result of experimental evidence; and so far we must suspend our judgment until events develop themselves. But there are certain aspects of the questions involved which not only admit of being discussed, but which really demand discussion at this moment. Thus, for example, Mr. Webb has now, or soon will have, a dozen of his engines at work, and on the results obtained with these a great deal may depend. In such a case as this the inventor is by the nature of things practically debarred from giving evidence. No disrespect will be meant, but nothing which Mr. Webb could say regarding his engines will be accepted as conclusive unless he can support his statements with well authenticated facts, and such facts must also be pertinent—a point very frequently overlooked by inventors. Thus, for example, Mr. Webb may state that his compound engines are burning but 26·6lb., as compared with 34·6lb. with non-compound engines on the London and North-Western Railway. Now, we have here an example of what may be termed the non-pertinent statement. In other words, such a fact has by itself little to do with the question at issue, which is, is the compound locomotive more economical than the non-compound? The railway world at large does not care a great deal if one engine on the London and North Western Railway is more economical than another engine on the same railway system; but it does want to know very much if the compound type of locomotive is more economical than any other type. To put this more clearly, we may say that while we accept Mr. Webb's statement that the compound engine is burning but 26·6lb. of coal per train mile, or about three-fourths of the coal needed by other Crewe engines, we can add that there are non-compound locomotives on other lines, working under almost the same conditions of load, speed, and gradients, which are getting on perfectly well with about the same quantity of coal that the compound engine is burning. Here, then, if we compare the compound engine with one type of non-compound, we find that it is very much more economical; if with another, we find that it possesses no advantage at all. But this is not all. No comparison of the kind can be complete which omits a statement of the quality of the coal burned. If Mr. Webb is using cheap coal, and his non-compound rival dear coal, then the comparison may, after all, be very much in favour of Mr. Webb. There is yet another point for consideration: How does Mr. Webb arrive at his results? Does he trust his drivers, or has he an independent inspector riding constantly on each of the new engines, and reporting on its performance? It is obvious that the men driving these engines have the greatest possible temptation to make them do well, and there are more ways than one, as every locomotive superintendent knows, of making an engine give a high duty. Of course we do not assert that due care has not been taken to get accurate results; but neither Mr. Webb nor any one else in his position can expect those to whom his invention appeals to be satisfied with anything short of a clear and definite statement of the precautions taken to obtain unimpeachable figures. Mr. Webb himself would be satisfied with nothing less as regards the invention of any other railway engineer; and we have no doubt but that in due time he will supply all that is wanted; but up to the present this kind of information is lacking, and judgment must therefore be suspended.

The whole system may be dealt with on a theoretical basis. Why, we may ask, should a compound be more economical than a non-compound engine? It is not necessary, fortunately, to enter into any discussion here of the merits of the compound system in preventing cylinder condensation and such like. The whole theory lies in a nutshell. An ordinary locomotive exhausts steam at a comparatively high pressure when it is hard worked. Thus an engine with 18in. cylinders, 24in. stroke, will deliver at each end of each stroke about 3·67 cubic feet of steam into the chimney, and this steam will have a total pressure, according to the speed of the engine and the point of cut-off, of from, say 100lb. on the square inch down. It is not likely that it will fall much below 25lb. above the atmosphere when the train is fairly heavy, unless on a falling gradient. We have here, then, absolutely wasted nearly 3·75 cubic feet of steam per stroke. If the cylinder were augmented in length, then it is clear that the steam might be permitted to follow the piston further, and so falling to a lower pressure give out a great deal of power. In other words, compounding a locomotive means nothing more than augmenting the cylinder capacity. It may be said that it is not quite a fair statement of the case, because in some instances the cylinder capacity has remained unaltered. This is only an apparent exception, as a smaller weight of steam is used at each revolution of the driving wheels in such a compound engine as that of Henschel with two cylinders only. Thus it is clear that the cylinder capacity is virtually augmented; in other cases it is actually increased. But precisely the same effect may be produced up to a certain point by simply putting in larger cylinders. Thus, let us suppose that an engine with a given boiler power has cylinders 16in. diameter and 24in. stroke. If, now, these are removed, and a pair of 18in. cylinders put in, the effect will be that of compounding. The engine can be worked much more expansively than it was before. The experiment has been actually tried, and with such unsatisfactory results that the cylinders have usually been lined up again; but the reason was usually that the load was increased at the same time that the cylinders were enlarged, and the engine performed worse than ever, because the boiler could not keep steam for the extra load behind it. If such experiments had had fair play, there would perhaps have been a saving of fuel. If not, then the prospects of the compound system are bad.

It must never be forgotten that the conditions under which a locomotive operates are of paramount importance in this connection. As a rule, passenger locomotives of the best type are so designed and loaded that very little work indeed is left in the steam as it escapes up the chimney. A glance at the diagrams taken from such engines will show that at high speeds expansion cannot be pushed further with advantage. The case is different with goods engines. We constantly find them hauling trains at slow speeds and working nearly in full gear. The power wasted up the chimney is then very great indeed. To such engines at such times more cylinder capacity would be invaluable. But for reasons very well understood, it is highly desirable that the increased capacity should be supplied rather by augmenting the number of cylinders than by increasing their diameter. Much is to be hoped, we think, from compounding goods engines. With them there are chances of saving fuel which have no existence in the case of the passenger engine. We may call attention here to the noteworthy fact, that while passenger engines exert daily a greater horse-power than goods engines, they burn much less coal per train mile, and the reason is that the passenger engine is seldom or never run in full gear, while the goods engine does the greater part of its work with steam admitted for at least 50 or 60 per cent. of the stroke. By augumenting cylinder capacity this would be avoided. The use of bigger cylinders than those now in use would do no good, because they also would be worked in full gear. The great advantage of the compound system is that the driver may do what he pleases, he cannot help work his steam expansively; and in this, much more than in the principle of compounding, will be found, we believe, the secret of all the economy that can be realised by compounding a passenger locomotive engine at all events.

MEAT AS FOOD.

The value of meat as food is due in a degree to its heat-producing properties, though in this respect it is surpassed by fatty and amyloid substances. It is as a tissue-building material, and as an excitant of assimilative changes in the tissues, both with regard to itself and to non-nitrogenous foods, that it is most useful. It is stimulant as well as nutritive, and it therefore holds a deservedly high place in the daily dietary. Experiment has shown that three-quarters of a pound of lean meat fairly represents the quantity per diem which, taken with other less nitrogenous matter, suffices to maintain a person of average size and weight in a normal state of health. Some there are who largely exceed this standard, eating freely of meat at every meal, and living all the time quiet, sedentary lives. Such carnivorous feeders sooner or later pay a penalty by suffering attacks of gout or other disorders of indulgence. But it is equally important to note that many others, especially women, healthy in all points but for their innutrition, are apt to err as far on the other side. Thus one meets with people who consume about a pound of butcher's meat in a week, or not even that. This fact has been fully brought out by Dr. Graily Hewitt, in his address to the Obstetrical Section at the recent meeting of the British Medical Association. He has likewise with much probability assigned this defect of diet as the chief cause of that general "weakness" which is so common among the antecedents of uterine displacement. The experience of many practitioners will confirm his observation. Different causes are at work to produce this kind of underfeeding—too rigid domestic economy, theoretical prejudicies, the fastidious disinclination for food which comes of a languid in-door life without sufficient bodily exercise, tight lacing perhaps, and many more. These difficulties are all more or less removable, unless, indeed, where absolute poverty forms the impediment. No effort should be spared to remove them. The advantages derived from a diet containing a fair amount of solid animal food could not be obtained from a purely vegetable or milk regimen without either unnecessarily burdening the digestive system with much surplus material, or, on the other hand, requiring such revolutionary changes as to quantity and quality of food and times of eating as would probably altogether prevent its general adoption, even were that desirable, into household management. In our opinion, such changes are not desirable, as being inadequate to secure their purpose.—*Lancet.*

THE MAGNETOPHONE.

The following account of an experiment on the effect of a rotating perforated disc on the magnetic field is from the pen of Prof. H. S. Carhart, of Evanston, Illinois, who calls the instrument, the magnetophone:—The experiments of Bell, Preece, and others, on the radiophone, suggested the possibility of interrupting, or at least periodically modifying, the lines of force proceeding from the poles of a magnet by means of a disc of sheet iron, perforated with a series of equidistant holes, and rotated so that the holes should pass directly in front of the magnetic pole. It is well known that the armature placed on the poles of a permanent magnet diminishes the strength of the external field of force by furnishing superior facilities for the formation of polarised chains of particles from pole to pole. This is the case even when the armature does not touch the poles, but is in close proximity to them. If a piece of sheet-iron be placed over the poles of a magnet without touching, and magnetic curves be developed on paper above the iron, they will be found to exhibit less intense and less sharply defined magnetic action than when the sheet-iron is removed. If, however, a small hole be drilled directly over each magnetic pole, the screening action of the sheet-iron is modified in much the same way as when a hole is made in a screen opaque to light, for the developed curves show distinctly the outline of the holes. If, therefore, the sheet-iron in the form of a circular plate, pierced with a number of holes, be rapidly rotated between the poles of a magnet and small induction bobbins, the action of the magnet on the core of the bobbins will be periodically modified, because of the passing holes, and hence induced currents will flow through a circuit including the bobbin. A disc of sheet-iron was pierced with two circles of ¼in. holes concentric with the disc, the number of holes in the two circles being 32 and 64 respectively. On one side of the disc was placed a horsesho magnet, with its poles very near the rows of hol the same champion of the theory in one of the city churches. He holds that the doctrine of direct descent of organic species from pre-existent species, throughout the geological record, is proved and certain. The process is from simple to complex forms of life. We are approaching a complete genealogy of all existing animals, including man. Facts confirm our belief that however constant species may appear to us now, they have been at some time variable.

On the grand question of glacial action, numerous papers were read, accompanied by discussion, in which the leading geologists of the country took part.

WATER POWER FOR ELECTRIC LIGHTING PURPOSES.

THE Brush Electric Lighting Company, of Rochester, New York, have erected a generating station on the west bank of the Genesee River, at what are called the "Lower Falls," in the city of Rochester. It is the intention of the company to utilise the water power of the river to drive turbines, which will be connected by pulleys and belts to a long line of overhead countershafting, from which the dynamos will be driven by belting. The following description of these works is extracted from the *Milling World*:—The works consist of a brick building or house, 100ft. long by 50ft. wide, and one story high, resting upon and supported by substantial substructural walls and piers of stone and brick, of various heights and forms and substantially based upon prepared foundations at various levels in the solid rock. The superstructure is spanned across its width at the base of the roof with nine trussed girders, which support the roof and the line shafting with its leading wooden-rimmed band wheel, 5ft. diameter by 4ft. 8in. face, and 18 pairs of fast and loose wood-rimmed pulleys, 42in. diameter by 13in. face each, making 360 revolutions per minute, and connecting by 12in. belts with 18 dynamo machines arranged upon the floor near either side of the building, giving them 756 revolutions per minute, at an expense of 40 horse-power each, making a total of 720 horse-power, supporting 720 lights, equal to 40 lights per machine, or one light per horse-power. The magnitude of the lights is not stated. The fast and loose pulleys which drive the dynamos were furnished by the Taper Sleeve Pulley Works of Erie, Pa., and they are so constructed and arranged that by one single and gradual movement of a double-headed oscillating cam, in connection with a belt shifter, the loose pulley, which hangs on a hollow independent bearing concentric with and surrounding the shaft without contact therewith, is thrown into gear and set in motion, so that as the cam is continuously moved forward through the extent of its parallel arc, which holds the loose pulley in gear, the belt is shifted on to it, when, by a little further movement of the cam, its inclined part at the rear end disengages the clutch, and the loose pulley, together with the belt and the actuated machines, cease moving and remain idle, until the cam is moved in the reverse direction, setting the idler in motion, shifting the belt into working position, and setting the machine in motion, when by the inclined part of the opposite end of the cam from that aforementioned the clutch is disengaged and the idler is again at rest, out of contact with any of the running parts. It is in contemplation to add nine more electric machines in this same building, to be driven by the same power, should time and circumstance demand it, making twenty-seven in all, producing 1,080 lights and requiring 1,080 horse-power. The power is to be obtained by the use of two Victor turbine water wheels, 20in. in diameter, made by the Stilwell and Bierce Mfg. Co., Dayton, Ohio. This wheel is noted for the extraordinary power developed by it, in proportion to its diameter, while at the same time the percentage of power in proportion to water expended (according to tests made at the Holyoke testing flume) ranks it among the highest and best. Another advantage possessed by this wheel is that its comparatively small diameter for a given power causes it to revolve so rapidly as to make a considerable saving in the cost of shafting and gearing.

The situation and surroundings of the water wheels and their appurtenances in this case are indeed unique and extraordinary, and indicate a perspicacity of discernment, acuteness of conception, boldness of design, and thoroughness of execution on the part of the projector, that stamps him at once as eminently qualified to place and execute a work like this, environed as it is by great natural obstacles and serious practical difficulties. To make a proper place for the flume or forebay, an open recess or bay was cut into the upper rock bank about 32ft. horizontal depth by 20ft. wide and 46ft. perpendicular depth, down to a level with the bottom of the head race. The bottom of this bay is about 45ft. below the floor of the superstructure, and extends under it about 28ft. From the bottom of this recess at its back side is a shaft about 12ft. square, sunk perpendicularly into the rock to a depth of about 90ft., to a point some 4ft. or 5ft. below the surface of the backwater from the river below the falls, which are nearly 100ft. high. From this shaft a culvert extending about 35ft. in height from the bottom of the shaft is cut through the rock out to the river. Between the top of this opening or doorway, and the bottom of the race and forebay, is about 55ft. vertical thickness of rock.

On the bottom of the recess in the rock, and partly over the shaft therein, is the flume, containing two U-shaped iron forebays, 7ft. high, opening toward the head race, and from the bottom of which are suspended two iron stand pipes, 76ft. and 10in. long by 42½in. in diameter, their upper ends opening into the forebays to receive water to supply the wheels. At one side of each stand pipe, and connected thereto with a short cylindrical tube, is an iron wheel case, with a draught tube attached to its bottom, and extending some 10ft. downward, and entering the backwater. Besides the support to the stand pipes by their connection with the iron forebays, they and the wheel cases are supported at their bottoms by iron beams. The turbines are placed in the wheel cases, and each one has about 58ft. of steel shafting, 3⅜in. in diameter, coupled to it and supported by bracket bearings projecting from the stand pipe. Each of said shafts has on it, near its top end, a spur pinion 21¾in. in diameter by 17in. face, 17 teeth, 4in. pitch, machine dressed. These gear into a core spur wheel 69¼in. in diameter, having 54 wooden cogs, and which is hung on near the bottom of a steel countershaft 6in. in diameter and 60ft. long, on which, near its top end, is a bevel wheel 88in. in diameter, 18in. face, 55 teeth, 5in. pitch, gearing into a core bevel wheel, 99·6in. in diameter, with 56 wooden cogs, 18in. wide.

This wheel is on a short, horizontal shaft, 6in. in diameter, having on its farther end, beneath the floor of the building, an iron spider carrying a wooden rim band wheel, 10ft. in diameter by 4ft. 8in. face, carrying a rubber belt 4ft. 6in. wide by ⅜in. thick, which connects with the heretofore described 5ft. leading band wheel on the main line of shafting above, and drives them.

The turbines operate under 94ft. head of water, including the 10ft. draught tubes, and are estimated to make 582 revolutions per minute, and develop 572 horse-power each, which, combined, equals 1,144 horse-power. The counter upright shaft makes 183·22 revolutions per minute, the counter horizontal shaft, with the 10ft. band wheel, 179·95 revolutions per minute, the main line shaft about 359·9 per minute, and the electro-dynamos 755·79 revolutions per minute.

TWIST DRILLS AND MACHINES FOR GRINDING THEM.[*]

By PROF. J. E. SWEET.

I HAVE recently had the pleasure of seing two different, thoroughly well studied, neatly designed, and spendidly built machines for grinding twist drills. They do not operate on the same principle, nor produce the same results, neither are they the only machines that have been built for the same purpose. The earliest machine brought to my notice with which it was proposed to grind twist drills on scientific principles, was the Van Haagen machine, built in '73 or '74. At the Centennial a machine of George Richards' design was shown in the exhibit of D. B. Whitney, for which the claim was made that it was nearer correct in its result, than the Van Haagen machine. One of the two machines first mentioned, the Sellers, it is claimed produces the correct form, but whether the result is like either that produced by that of the Van Haagen or Richards machine, I do not know. It is decidedly different in its manner of working, and the device for holding the drill is unquestionably better. The other new machine, built by the Pratt and Whitney Company, differs from all the others, not only in design and method of holding the drill, but also in the shape of the point and cutting edge given the drill. I do not know whether it is claimed that the point and edge are theoretically correct, but according to my notion the best form is approached.' Let it be understood that I intend to say nothing except in praise of both the Sellers and Pratt and Whitney machines, believing that both produce exactly what their designers intended they should produce, and, too, what each believed to be the best possible form for the work to be done.

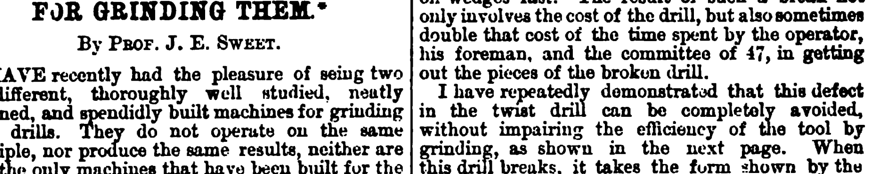

FIG 1 FIG 2 FIG 3 FIG. 4 FIG 5

If the cutting edges of a straight lip twist drill run in radial lines completely to the centre of the drill, then the case would be simple, but being neither radial nor running to the centre complicates the case. In drills of different sizes, and often in drills of the same size, and in different parts of the same drill, the conditions vary, so that there must be some sort of a compromise. Any method of grinding that produces a curved surface on each lip produces something approaching a cone at the point, and as a true cone would not work at all, as it would act as a centre and not cut its way into the metal, so the form most nearly approaching the cone must be worse for that part of the drill, and in that respect the Pratt and Whitney method leaves a bevel along the cutting edge of each lip, and by that means leaves the point more nearly wedge-shape than the method of grinding a full curved surface. My own idea is that, so far as the cutting edge of the lip is concerned, if the grinding starts from the edge with a proper degree of clearance, it makes no difference whether the following surface is straight, concave, or convex, provided the straight or convex surface does not leave a point to drag in the hole. Let the Figures 1, 2, and 3 represent the developed surface of one lip of a twist drill. Fig. 1 fairly represents the drill as sent out by the makers, and as left by the scientific grinding machine; Fig. 2 a shape they sometimes get into when ground by hand, and Fig. 3 the form they would assume if ground a straight bevel, and which shows that the back corner would prevent the drill from cutting. So far as the cutting edge is concerned, I believe all would cut equally well, but in the ones shown in Figs. 1 and 2 the points will be conical, and the one in Fig. 3 wedge-shape. Any firm using twist drills exclusively finds, I think, that it involves quite an item of expense, and that the cost is as much attributable to breakage as to actual wear. A large proportion of the breakage expense comes from the drill commencing to break at the bottom of a deep hole, and being shattered all the way up to the top. Why a twist drill breaks in this peculiar manner is easily shown when the direction of the fracture is observed.

When a drill, as ground by the makers, breaks by being forced too hard, the break invariably takes place as shown at A, Fig. 4. The piece broken off wedges fast, and unless the machine is instantly stopped a succession of breaks takes place, as shown at B, C, D, &c., because each piece broken off wedges fast. The result of such a break not only involves the cost of the drill, but also sometimes double that cost of the time spent by the operator, his foreman, and the committee of 47, in getting out the pieces of the broken drill.

I have repeatedly demonstrated that this defect in the twist drill can be completely avoided, without impairing the efficiency of the tool by grinding, as shown in the next page. When this drill breaks, it takes the form shown by the line E, Fig. 5, and the piece does not wedge, leaving the drill free to rotate. I have also demonstrated by actual trial that it is impossible to get any one, young or old, skilled or unskilled, to so grind a drill, however many times he may be shown or made to acknowledge the superiority of the method. I shall probably continue to believe this to be the best way to grind a twist drill until I meet with some man who can get as much hole in the same piece of metal, with the same expenditure of power, time, and drill, ground in some other way, as I can with one ground in this style. It is possible that that if a twist drill grinding machine were available for grinding in this shape (and it would seem that the problem would be simplified by adopting this form), then people might be induced to adopt it.

Twist drills, however ground, are a money-saving investment, though it is not infrequent to find mechanics raise powerful imaginary objections to them. One man says, "You can't ream out a

[illegible]

[illegible] the late C. Darwin, [illegible] translated by Mr. D'Arcy [illegible]

[illegible] Edinburgh has now taken [illegible] quarry at Granton having [illegible] and the necessary [illegible] The surplus funds derived from [illegible] Fisheries Exhibition in Edinburgh have [illegible] supplemented by an anonymous donation [illegible] and the Station Committee has just [illegible] with its work, which [illegible] undertake a scientific exploration [illegible] of the Firth of Forth and the adjacent parts of the North Sea: and to establish a marine station for biological investigation and research." It is hoped that the institution may be in full working order by March or April next.

By the kindness of the trustees of the Gilchrist Fund, the committee of the Royal Victoria Coffee Hall have been able to arrange for the delivery of six "Penny Science Lectures." The lectures will be as follows:—October 2 and 9, "Ice, Water, and Steam," by Mr. W. Lant Carpenter; October 16, "Life," by Mr. P. H. Carpenter; October 23, "Comets," by Mr. E. B. Knobel; October 30, "The Rights and Feelings of an Animal," by Mr. C. A. V. Conybeare; and November 6, "Food and Feeding," by Dr. B. W. Richardson. The lectures will be illustrated with the oxy-hydrogen lantern.

The accounts of the experiments with electrical trams in Paris are misleading in one particular. There never was any doubt that engineers could do their part of the work; but there is much reason to doubt whether "the estimated cost is one-half that of horse trams," or, being so, whether some mistake has not been made by the estimator. M. Geraldy has already pointed out that the expense of driving cars fitted up with two tons and a half of accumulators is seriously objectionable."

Another matter concerning which misleading statements are made, is the transmission of power by electricity. Here, again, there has never been any doubt that power could be transmitted over considerable distances by means of electricity; but when we find it stated that M. Marcel Deprez obtained a return of 62 per cent. we ask for proof. The power of a waterfall about [illegible] miles from Grenoble was made to produce a motive effect equal to seven horse-power (some accounts give eight horse-power), which was utilised in working various machines; but no definite information is afforded as to the actual amount of power put into the line at the other end.

The International Society of Electricians has been founded in Paris under the presidency of the Minister of Posts and Telegraphs. The annual meeting will be held in March or April, and the ordinary meetings on the first Wednesday in each month from October to June. The temporary offices are at 99, Rue de Grenelle, Paris.

The meeting of the Electrical Units Conference in Paris has been postponed until April 2, 1884.

Baron Nordenskjold's expedition in the *Sophia* arrived at Julianshaab on June 17, and proceeded to Ivigtuk for coals. The voyage to North Greenland was resumed on June 26.

Mr. Webster Gillett, of Flushing, Long Island, is credited with the invention of a telephone by means of which conversation can be carried on between points 2,600 miles apart. The inventor's object, however, is to construct a telephone capable of use with the Atlantic cables. The device appears to consist of a tin-plate disc 13in. in diameter, from the centre of which projects a funnel-shaped resonator. On the opposite side of the disc there are ten "deviating points" held in position by rubber arms. These deviating points are needles which pass through rubber cushions into cylinders containing granulated carbon. These ten points are connected up with ten batteries, and the same number of induction coils, and a plug switch puts one or more, or all, the points in the circuit. Mr. Gillett is said to claim that his ten points, coils, and batteries have about six times the power of one battery; but the chief feature of his invention is the rubber cushions through which the needles penetrate to make contact with the granulated carbon.

A series of "Popular Evening Classes" has been arranged for the ensuing session in connection with Anderson's College, Glasgow. The lectures will be on "Geology," by J. C. Christie; "Electricity and Magnetism," by Prof. Jas. Blyth, M.A.; "Anatomy and Physiology," by Prof. A. M. Buchanan, M.A.; "Music," by Colin Brown; and "Chemistry," by Prof. W. Dittmar. The fee for each course of 25 lectures is 2s. 6d., and that includes the use of the library and reading room! The lectures are delivered at 8 o'clock on the evenings specified in the syllabus.

Mr. Fletcher, of Warrington, has recently added to his numerous inventions in connection with the combustion of gas a special form of furnace bar, which can be made up into furnaces of almost any size and shape. Where a blast of air is available, a special attachment is supplied which will enable 1,000 cubic feet of gas to be burned per square foot of burner surface per hour, equal to, say, 40lb. to 50lb. of coal per square foot of grate. With ordinary day pressure of gas, the bars burn about 100 cubic feet per square foot.

LETTERS TO THE EDITOR.

[*We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.*]

All communications should be addressed to the Editor *of the* English Mechanic, 31, *Tavistock-street, Covent-garden, W.C.*

All Cheques and Post-office Orders to be made payable to J. Passmore Edwards.

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original." —*Montaigne's Essays.*

OPTICAL MATTERS.

[21821.]—Our friend "Bow" discharges his arrows in so many directions that he must not be surprised if some of us that he has smitten try to turn him into a target. As regards spherical chromatism, I cannot say whether or not I am the first to touch upon it. Like "Bow," I should very much rejoice to meet with a book in which it is thoroughly investigated. Cannot our friend give us something about Airy's work in this branch of optical mathematics?

He is probably right in assuming that "mathematicians tacitly assumed that altering the character of curves would seriously affect the balance of spherical aberration, and would produce but small effect on colour." But, unfortunately, it is this neglect of small matters which makes all the difference between a "good" o.g. and a "best" one. "Bow" must be aware that the connection between sp. and chr. aberrations is as close as that between the string and the bow, and what alters one affects the other also, although it may not be to the same extent.

"Bow" then goes on to say, "Whereas it would seem that having destroyed sp. ab. by proper ratios of radii, we may sometimes play considerable tricks with the nature of the curve." It does not seem so at all. The chief part of chromatic error is removed by a proper ratio of radii, and then the surfaces are worked so as to remove the spherical and residual chromatic errors as much as possible. If we are to balance sp. ab. by curves calculated on the basis of spherical surfaces, which is, so far as I know, the only way in which the problem can be successfully dealt with, there is not much liberty for playing tricks with the nature of the curves. Of course, it may be possible for a clever artist to work such surfaces not exactly spherical, and still get the combination to give good definition; but could anyone, even the artist himself, say how the final surfaces differed from sphericity?

This may be regarded as a sort of optical legerdemain; but I have laboured in my essay to show that it is, or at least may be made, part of a regular system of surface alteration. Let us look at it in the light of reflection. A parabolic speculum gives no aberration. Why? Because its surface is of such a nature as to send all the rays to one point. Just so with the object-glass: each of its surfaces might (I do not say can) be so fashioned as to direct its own incident rays to one particular focus. There would then be no inherent refractive or spherical aberration, and if spherical error be not introduced, and consequently no positive and negative errors, then I contend that the residual chromatic errors must also be considerably lessened. Can "Bow" show it to be otherwise?

The really difficult matter connected with the successful application of mathematics to the object-glass is to find what relation of foci, or—which comes to the same thing—what ratio of radii will best correct the chromatic error. I have, as yet, met with no rule which will give this satisfactorily. Ordinarily it is said that the foci should be as the dispersive powers; and this, perhaps, might not be far out, if we could get to know exactly what the dispersive power of a substance is.

Dr. Hastings has developed a new theory of focal proportion which is said to give a very satisfactory result. I have no knowledge of it at present; but I trust some American friend will copy all or part of the article and send it to these columns. Our esteemed contributor Mr. J. A. Brashear has kindly sent me two copies of the *Sidereal Messenger*, each containing an article by Dr. Hastings: from the first of these I make the following extract. After alluding to the determination of the refractive indices, Dr. Hastings says:—

"With the data thus acquired, the curves for a four-inch objective from the two glasses studied were calculated, such that the spherical aberration for rays of mean wave length should vanish, and under the hypothesis that the sum of the squares of the chromatic aberration for other wave lengths, weighted according to their respective luminous intensities, should be a minimum. This was the naturally suggested criterion for determining the most advantageous value for the dispersive ratio, and, although it did not differ very greatly from the method chosen by Fraunhofer without leading to a successful issue, it was hoped that the difference would be sufficient to correct his error. The objective was carefully constructed according to these curves, though it was first found necessary to improve the form of the spherometer so as to greatly increase its delicacy. The experiment proved a failure. Though the telescope was free from spherical aberration, thus proving the workmanship good, the colour correction was decidedly too small. A careful remeasurement of the surfaces, and a repetition of the computations demonstrated that the theory was certainly at fault.

"A reconsideration of the whole subject gave rise to quite a different method of determining the most appropriate value for the dispersive ratio. By it the question of limiting extent of chromatic aberration was not considered at all, but only a condition as to the amount of light energy sent very near the geometrical focal image of a distant point. This theory (*American Journal of Science*, Vol. XI. April, 1878), after having been once formulated, was so satisfactory that there was no doubt as to its success even before testing it; but, as what follows will show, that did not lead to any neglect of rigorous tests."

I trust some of our friends who have access to the above journal will let us have particulars of a theory which can give so satisfactory a result. All who have given any considerable amount of attention to the study of optical chromatics most have wished to see it dealt with in a more satisfactory manner, and this Dr. Hastings appears to have accomplished.

Orderic Vital.

ARCHIMEDES.

[21822.]—In the "E. M." of August 17, 1883, I notice a letter, No. 21706, from Mr. B. J. Hopkins, relative to an unusual appearance seen by him May 19, 1883, upon the floor of the lunar crater, Archimedes.

It will, perhaps, be satisfactory to Mr. Hopkins and to other readers of your paper who are students of selenography, to know that his statement descriptive of the remarkable phenomenon to which he has called attention, has been subsequently confirmed by a careful observation here, without any knowledge of the same having been previously seen.

On the evening of the 14th of June, 1883, while sweeping with a 4in. ach. along the abrupt declivity of the lunar Apennines, my attention was suddenly arrested by the unusual distinctness of the bands upon the floor of Archimedes, a crater which I have, during the last ten years frequently and carefully observed under various shades of illumination, so that I could scarcely be deceived as to what I saw, and have several times subsequently seen, perhaps more distinctly than your correspondent of Dalston, owing to the clearness of the atmosphere in this part of the States. The description he has given, however, strictly agrees with what I have observed.

It is to be hoped that this interesting object will be carefully scrutinised by the aid of the highest optical power that can be brought to bear upon it, so as to elicit, if possible, something as to the cause of its present unusual appearance.

A PENNY WATER CLEANER.

[21823.]—There seems to be, just now, a scare, partly natural and partly artificial, about the wholesomeness of water, in view of a dreaded invasion of cholera. Nobody knows, on direct evidence, whether cholera or fever be due to germs. The evidence is indirect. Such illnesses, or rather their causes, may be brought, like thistledown, on the wind, or like ringworm, they may be brought by first or second contact.

The source of ill multiplies quickly. It is therefore like yeast. It is stopped by the heat of boiling water. So is all animal and plant life.

The balance of evidence now, I suppose, is that catchable diseases are due to living germs.

Now it may be taken for granted that one and the same living thing, whether plant or animal, cannot live long both when wholly and permanently immersed in water, and when wholly and permanently immersed in air.

If there be a germ whose habitat is water, and if it be exposed to the air, it faints and then dies, and is straightway burnt up. You will guess now that the moral of the penny purifier is aëration.

Subtle as the disease germs in water may be, they shall not escape the touch of the oxygen.

Therefore, in finally purifying water by filtration, let it run over abundance of surface. And, while so running, let it be freely exposed to the air. A porous filter without aëration—a mechanical filter—is of some use. You can get rid of dead cats, mice, flies, and all things greater in least diameter than the least diameter of the pores of the filter, through which pores they try to pass. But what would be the use of keeping a mass of putrid matter at the top of your filter? You do not thus get rid of germs, nor of organic matter, which is the hot-bed of germs.

In the water which has passed through some of the most esteemed filters, I have found "moving organisms" at least as large as the vinegar worm. I do not say that these came through the filter: they may have reached the water after it was filtered, in one or other stage of development. They were undoubtedly bred in the filtered water. Because, although the filter may have removed the poultry, it did not remove the grain upon which chickens feed, nor probably the eggs from which they spring. I, for my part, would no more hesitate to drink such water than I would hesitate to drink water from a brook in which there were trout or tadpoles. Nor would I more refuse to drink of water in which there were dead organic matter than I would refuse soup, or milk, or beer.

As to your cisterns, keep them covered, but not too closely. Canvas is better than wood. Light is good. As to the cleansing of cisterns, a very little arithmetic will prove that if no dirt reaches the cistern from the air, the average purity of the water which is drawn from the cistern is the same as that of the water which enters the cistern. If you clean out a properly covered cistern daily you gain only in the benefit you derive from the physical exercise. At all longer intervals, such cleansing is folly. This is of course assuming that the water, as given to us from the companies, is good. So it is—excellent! London is the only capital in Europe where one can rely upon getting a glass of fair water from the tap.

Then what is the use of filtering the cistern water? Because contagion may exist in or near the house.

And so, to come to the penny filter. Take a flower-pot and a brick. You can get three flower-pots for a penny—also three bricks for a penny. However, let us say a flowerpot and a brick for a penny. Break the bottom out of the flowerpot in such a way as to leave edge enough to hold up half a brickbat. Let one corner of the half brickbat stand out through the bottom hole. Break up the rest of the brick into bits about as big as a quarter of a walnut. Throw them into the pot. Soak the whole over night in a pail of water, and let it drain.

Let the water you want to clean drop upon the middle of the chips of brick. After a few hours the water which drops from the bottom will be wholesome and fair water. Most filters pretend to purify water mechanically. They clarify rather than purify. Others depend upon some curious property of the medium, like animal charcoal. Such cunning matters, have to be frequently reviewed. The purifier I suggest combines a rather coarse filtration with an effective aëration and something of a specific chemical action as well. But its beauty is its cheapness. Only one penny, and as good as any other.

Fredk. Guthrie.

Science Schools, S. Kensington.

ORNAMENTAL TURNING AND THE PROPOSED STANDARD MANDREL.

[21824.]—In reply to letter 21785, I have much pleasure in presenting the engravings below, as reproduced from p. 64, of Amateur Mechanical Society's *Journal* (No. 25).

Fig. A represents a longitudinal section of the standard mandrel-nose, with its steel collar and the portion of lathe-head which carries it.

Fig. B represents the cross sections of the mandrel-nose. The outer circle represents the cross section of the cylinder base, which should be 1·050in. in diameter. The next circle represents a cross section of the full nose before it is threaded out, and should be 1in. in diameter. The excentric circle represents a cross section of the nose after it has been threaded out, and should be ·9in. in diameter. This section of the threaded nose is practically a circle, though not exactly so. Its excentricity is half the depth of the thread, and its figure will always be the same, whatever part of the nose is cut through; but, as the section traverses the screw this circle will rotate upon its own centre. It shows the extent to which the mandrel-nose is weakened at its base by the present practice of turning out the thread. In the mandrel here represented this turning out of the thread merely to its bottom would diminish the cross-section area from ·5106 to ·3770 square inch. The third concentric circle represents the outline of the stem of the screwed nose, and should be ·8in. in diameter. The innermost circle shows the bore of the mandrel, and should be ·4in. in diameter.

Fig. C represents an enlarged cross section of the

The half-turn of a double screw-thread might be made to answer perfectly in fixing these small chucks.

The steel collar should be coned so far as to sit solidly in its position without shifting backwards under pressure from the other centre when drilling or turning heavy work. The larger its longitudinal surface for the support of the mandrel neck the greater its endurance, and the more lightly will it run because of the diminished tendency to deflection in the mandrel.

arm, which in many cases is very useful for carrying wheelwork to co-ordinate the movements of tools, &c., with the rotation of the mandrel. If not required for this purpose, it serves to give fixity to the collar in which the mandrel rotates and traverses.

The question as to how a working mechanic may test his gauges is one to which a very satisfactory answer may, owing to the munificence of Sir Joseph Whitworth, now be given. On application to the Standards office at the Board of Trade, Whitehall, a grand series of most accurate gauges may be used by any intelligent working man, and by them any gauges that he may make for himself may be compared and measured to the extreme limits of mechanical accuracy. In measurements of size, Sir Joseph Whitworth has shown that the sense of touch is vastly more accurate than that of sight. **James Edmunds.**

Grafton-street, Bond-street.

THE PRIZE ESSAY ON THE COMPENSATION BALANCE.

(*Concluded from page* 18.)

CHAPTER IV.—It is desirable that a statement be given of the causes of error, and of the Laws that connect the changes of Temperature with the times of oscillation.

[21825.]—THE cause of error of the compensation balance is simply this:—The balance in heat does not approach the centre fast enough to exactly compensate for the loss of the elasticity of the pendulum spring; and that in cold it recedes from the centre too fast, or does not act in a geometrical ratio to exactly compensate for the spring's elongation by heat, or by its increased elastic force in cold.

The Astronomer Royal, by a series of experiments, in the year 1859, tried upon a chronometer with a plain uncompensated brass balance, by which it was shown that there was a uniform decrease of rate for equal increments of temperature measured by a mercurial thermometer, amounting to 6·11 secs. in 24 hours for each degree of Fahrenheit's scale. I believe no other authentic table was ever published in this country, although the celebrated geometrician, Daniel Bernoulli,* conjectured the same in 1747. It was established as a matter of certainty by Berthoud in 1773, with the following result:—One of his marine watches, in passing from 0° to 27° (Réaumur), 32° to 92° (Fah.), it was found that the loss per diem by—

July 6 to July 9 November 12 to November 19	− 142·5 + 225·3	367·7	99·3 40·9	58·4	*6·30	Mean daily variation for one degree of temperature.

* This difference is caused by the Chronometer having slightly accelerated on its rate.

The same Chronometer, with Compensation applied, gave the following results:—Mean Temperature—88°, 55°, and 32°; Mean Daily Rate—0·0 seconds, 0·0 seconds, and 2·4 seconds losing.

By a study of the table published by the Astronomer Royal (see above), it will be seen that the error is the same with an uncompensated brass balance of 6·11 seconds for every degree of temperature. The change is regular and uniform, passing through heat, cold, and intermediate temperature. Many watch makers are not aware of this great error of 6·11 secs. in 24 hours for every degree of temperature in a watch with an uncompensated balance; and before commencing the adjustments of a chronometer or watch, it will be well to consider the amount of error to be compensated for in a range of temperature of 60°, which is 6¼ minutes; and this error the ordinary compensation balance will correct to within $\frac{1}{10}$th of a second for every degree of temperature. From what has been stated in the former chapter, the error has been shown to be six seconds for 60° of temperature. This error, strictly speaking, does not take place in geometrical progression, nor will the error be so much as one second for the first 10 degrees. As the balance is nearly perfect for 10° of Fahrenheit, provided that it has been accurately adjusted, say at 60° or 90°. Mr. Hartnup, of the Liverpool Observatory, in his report for 1872, has calculated with mathematical precision that for a variation of 30° from the maximum gaining rate of the chronometer the loss will be 2·7 daily, and that this error for a longer range of temperature increases as the square, as per table,—

	Seconds.
For 10°	0·3
For 20°	1·2
For 30°	2·7
For 40°	4·8
For 50°	7·8
For 60°	10·8 or 36 times

the amount of the first error of $\frac{3}{10}$ths of a second for 10°, and so on increasing as the square. But by compensating the balance and dividing the error, the following results will be given by a chronometer timed in 60° range of temperature—

		Seconds.
At 90°	=	0·0
At 60°	×	2·7
At 30°	=	0·0

and on the other hand, the performance of the same chronometer with all the error carried over to the cold would be

		Seconds.
At 60°	=	0·0
At 90°	=	0·0
At 30°	=	6·1

but for all practical purposes, and without going into mathematics, and in this essay it has been my object to avoid all calculations but those obtained from practice alone, I find the error to be rarely less than 3 seconds, so that in 30° of temperature our calculations coincide within $\frac{3}{10}$ths of a second, and in a range of 60° of temperature within $\frac{1}{10}$th of a second, so that the mariner by this method may determine the rate of his chronometer to the greatest exactness, if he will take the trouble to do so; he should always be informed of its error in the three temperatures, or be informed of the temperature his chronometer has its maximum gaining rate, but so long as owners of chronometers allow them to be rated by anyone without the appliances for determining the error, so long will they be kept in strict ignorance of the error of their instruments, thus proving the error to arise through the balance altering its form by the elongation of the arm by heat, and the shortening of the same by cold, carrying with it the rim; thus altering its shape, and not remaining a true or a perfect circle under all changes of temperature. The balance by its proper adjustment can be made to go accurately at two points of the thermometer, but at no other, as seen by the diagram Fig. 1. The arcs of the balance, being composed of brass and steel, are so affected by heat as to curve inwards, carrying the weights upon them nearer to the centre, and thus diminishing the effective diameter of the balance at the same time that the strength of the spring is relaxed, but the centre of gravity of these arcs does not approach or recede from the centre in a straight line. Excess of curvature would cause each arc to take a spiral form; and in some positions the weights approach to or recede from the centre faster than in others. Hence it is found that as the arcs straighten outwards, the amount of movement increases in a greater degree than the spring becomes strengthened. If we connect the centre of gravity of the compensation weight with the junction of the arc with the arm of the balance by the dotted line *d*, we shall see that a decrease of temperature, strengthening the arc, increases the length of this dotted line. The amount of onward motion is, therefore, gradually increased as the temperature falls, and with it the inertia, and the chronometer loses. Drawings have been made, and theories asserted; but I clearly claim, by comparison of the tables given by the Astronomer Royal, that the real error of the ordinary compensation balance is one-tenth part of a second for every degree of temperature, and that the balance of ordinary construction is capable of correcting, and does correct, nine-tenths parts of the whole error of 6¼ minutes for a range of 60° of Fahrenheit's thermometer.

This is the true cause of error that cannot be compensated for without the addition of auxiliary compensation or check-pieces, or by balances of similar construction to Mr. Hartnup's, Mr. E. J. Dent's, or Mr. Kulberg's—the latter, as before stated, apparently combining the principles of the other two gentlemen's inventions; but in a commercial point of view no balance for general good performance has taken the place of the ordinary constructed compensation balance, which, if well and properly adjusted, its error is shown, and takes place as regularly as temperature is indicated by mercury on the scale of a thermometer.

In the works of a chronometer or watch the barrel and fusee revolve so slowly that its motion is quite imperceptible; and through the teeth of this wheel is conveyed the power or force which puts the whole instrument is motion. Again, the escape-wheel revolves with great rapidity, but with so little apparent power, that a very slight opposing pressure will stop it altogether. Loss of power: from failure of the oil, friction, defective compensation, where will be the fine performance then unless the chronometer has had its isochronal and compensational adjustments carried out to all intents and purposes? The chronometer represents itself to be a timekeeper (with an error it is true), which can be tabulated with a degree of accuracy almost to determine the longitude within a mile for any distance.

CONCLUSION.

In writing this Essay on the Compensation Balance and its adjustments, it has been my object to adhere strictly to the conditions for which the essay was to be written, and to give as much practical information upon the subject as my humble ability permitted. I have carefully avoided all theories and probabilities, and given results obtained from practice and experience. Much has been written upon this subject before, but it has failed to give that practical information intended, and they have been mostly theoretical publications. The chronometer maker looks to the seconds-hand, which tells him its true tale; and how often has this hand denoted the tale of unsuccessful plans, false theories, and great disappointment? If this essay will prevent more of this loss of time and disappointment my task will have been well fulfilled. In every good chronometer the practical and honest artisan imparts to it a value that cannot be seen, or displayed upon its highly-polished surface or outside case, which are looked upon by *some persons* as a thing of more importance than the intrinsic merit, or unappreciated talent, bestowed upon the chronometrical adjustments. The time and talent required in bringing instruments up to the high degree of perfection required for the especial performance of high-class chronometers, such as I have alluded to in Chap. III., is known only to those who devote their practical skill in endeavouring to attain this degree of perfection. Excessive competition and a false endeavour to please the eye have caused many men to lose sight of the requisite adjustments the ordinary compensation balanced chronometer is capable of, and is actually necessary that it should receive. In an honest chronometer the springe devotes his time and talent to isochronal and con

---

* C. Frodsham on "The Isochronism of the Balance Spring."

[21829.]—Referring to Mr. Stretton's letter, page 15, I would again explain that the braked train as running on the Liskeard and Caradon Railway does not represent the *entire design*; and consequently it is not urged or assumed that as there exhibited it complies with the Board of Trade conditions. It has been explained that, owing to mineral trucks unfitted with connections being run between the engine (at present also unfitted) and the coaches, the brake was "returned" as not complying. I have been endeavouring to show even the non-technical readers that the coaches were fitted with the apparatus merely to prove (as it has amply succeeded in doing) that the speed of a train can be as readily and effectually checked by a simple mechanical arrangement actuated, not by an exterior foreign energy, but by the momentum of the train itself. It is true up till now no brakes, whether mechanical or atmospheric, have proved entirely satisfactory. This is admitted on all sides; the extreme diversity in the systems used conclusively showing that no decided approval exists sufficiently to warrant any one of them becoming the universal brake. It is considered by many eminent engineers and inventors, that the solution of the brake question will be found before long, in some simple mechanical arrangement worked by the ordinary carriage axle. I trust, with Mr. Stretton, that before long we may have the opportunity of seeing this brake working on a large number of vehicles at once. No doubt at present very considerable prejudice exists against mechanical brakes, and greatly deters their receiving the attention they deserve. It may almost be regarded as an axiom, that the simplest means of securing a result is the best; therefore any apparatus capable of obtaining all the advantages and more, must eventually supplant those complicated arrangements wholly dependent upon an external source for supplying the power to absorb an energy, which might itself be used to obtain the result required.

Imprimatur.

MICRO. SLIDES.

[21830.]—The long evenings are approaching, and I am sure that a great many of your readers would be delighted, as well as be profitably employed, if some of your subscribers who are experts at the preparation of micro. slides would give clear and detailed formula for their preparation, especially for the preparation of those from *chemicals*, many of which are so splendid with the polariscope.

I shall be pleased to add my contribution to what I now suggest, having for some years successfully made many such slides; but have often signally failed by reason of the vehicles used for mounting them, dissolving the crystals. Information on all these points would continue your valuable weekly as an "educator," and be hailed with great satisfaction by many of your subscribers and readers.

If a "Micro. Slide Exchange" could be established, it would be another great boon; as when an operator has his arrangements made he can easily produce a dozen; what not required, to go in exchange for what perhaps he has not a facility for producing.

R. W. A.

LEGAL REPLIES.

[21831.]—Horse and Hedge—Damage (51558.) A. had a right to let his horse graze upon his own field, and if he strayed into the querist's field of corn adjoining, then the only question is whose duty was it to repair the hedge between the two fields? If A. is right that his horse strayed through a hole in the hedge belonging to the querist, then he is not liable. The only way to decide the question will be by an action in the county court for the value of the corn damaged. The expenses of the valuer can only be obtained if they are allowed by the judge in his attendance as a witness at the hearing of the case.

Building Society—Sale of Shares (51561).—This looks like an actual sale of the shares, as the price was agreed upon, a deposit paid, and the books handed over to the buyer. If this was all that had to be done by the seller, the sale was complete, and he had better sue the purchaser for the agreed price, giving him credit for the deposit as a sum paid on account. Presuming, however, that the transaction cannot be considered as a sale, then the querist's only course is to sue the buyer for specific performance of the contract on the basis of the letter, and the payment of deposit on a first performance. Probably, since the Judicature Act, this form of relief and remedy can now be obtined in a county court as well as in the High Court of Justice.

New Bankruptcy Act (51609).—There is no clause protecting property from seizure by landlord in this Statute. Probably the querist means Section 122, which protects a debtor's property to the extent of £20 from seizure under a County-court execution after an administration order has been made against him on the ground of his insolvency. But this has nothing to do with rent. Section 122 is of great importance to County-court debtors and creditors equally, and it should be read carefully by all concerned. I have just published the whole of the new Bankruptcy Act, with an introduction and notes, which I can send by post for twenty stamps.

Fred. Wetherfield, Solicitor.

CHIME CLOCK MAKING.

[21832.]—Various causes have hitherto prevented the completion of the articles on Chime Clock making, and I must apologise for the delay.

The hour striking train was last described. Fig. 4 shows the chiming or quarter train. The barrel A carries the great wheel which drives the second wheel and pinion B; the front pivot of this pinion projects through the frame, and has the locking plate C squared on to it. The wheel B drives the nut of 40 which is attached to the chime barrel D, and also the pallet wheel and pinion E. The warning wheel and pinion F are driven by the wheel E, and the fly pinion by the warning wheel, the back pivot of the fly pinion being carried by a cock G as in the striking train. The spring H on the back frame and the lever I on the front frame are for pumping the chime barrel to play either on eight bells or the Westminster chimes. This arrangement will be fully described when the chime barrel is pricked and pinned, directions for which I will give in my next.

W. Baldwin.

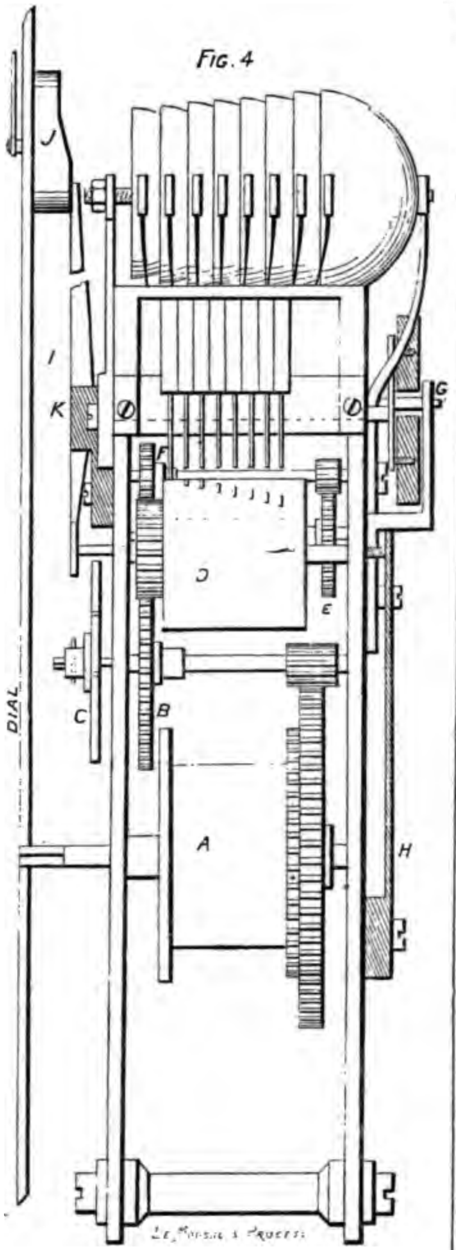
FIG. 4



IOTA^1 LIBRÆ. (♅ VI. 44. = SH. 376.

[21833.]—The wide pair ι^1 Libræ was discovered by Sir W. Herschel on the night of May 24th, 1781. The measures since have been both few in number and very discordant. The original record in the *Phil. Trans.*, Vol. LXXII. (1782), p. 154, is:—"May 24, 1781. Double. Very unequal. L. w.; S. dusky r. Distance 1′ 5″ 10‴, not accurate. Position 22° 31′ *s.* following." Sir John Herschel, in his Synoptical Catalogue of his father's observations (Mem. R.A.S., Vol. XXXV., p. 91), writes:—"A B 1782·359 112·52° 1 obs. A B 1781·392 59·07″ 1 : : obs. In printed Catalogue:—"Distance = 1′ 5″ 10‴, corrected in margin by C. H. [Caroline Herschel] to 59″ 4‴. Correction verified." I find the following in the MSS.:—"May 24, 81, 59″ 4‴ [written over some figures, evidently 1′ 5″ 10‴, which have been erased with the aid of a penknife]; superficial measure very unequal the small one very obscure. May 12, 82. L. w., S d r. Posit. . . . 22° 30′ *s.* foll." It is a little strange that as the paper was read before the Royal Society on January 10th, 1782, the date of the measure of the angle should be given as May 12th, 1782; but this measure was probably added later on. The star was next examined by Sir J. Herschel and South (*Phil. Trans.*, CXIV. (1824), Part III., p. 410).

It is placed in the Appendix as being one of those "less perfectly measured, or of which, from their uncommon difficulty, the observations are too precarious to be received as satisfactory." The first measure is stated to have been made on May 28th, 1822, with the *five* feet equatorial, position 23° 45′ *s.f.*, distance 50·629″, "little better than guessing"; and the star was again observed with the same instrument on April 11th, 1823, position 18° 30′ *s.f.*, distance "about 60 seconds," and mention is made of a distant third star, precisely in a line with A B; the mean of the two evenings' measures being 21° 39′ *s.f.* 50·629, 1822·84. H and Sc. quote Sir W. Herschel's result as 22° 31′ *s.f.* 59·05″, observing that "the diminution of distance (could it be fully depended on) would be very remarkable." With the exception of a measure (?) of Smyth's (110·5° : 51·3 : 1837·43), it seems to have been neglected until β. discovered the duplicity of the companion with the 18½in. at Chicago in 1878. The mean of his observations gives A.B. 110·6° 57·40″ 1878·98 (five nights); B C 24·8° 1·32″ 1879·00 (five nights), and he suggests (Mem. R.A.S., Vol. XLIV., p. 185) that Sh.'s measure should be 58·63″ instead of 50·63″. I find, however, that a very curious error has been committed by H$_2$ and So. They give, as usual, the value of the measured distance in parts of the micrometer employed, and it will be seen that, instead of using the values of the 5ft. equatorial micrometer, they have taken those of the 7ft., with which the observations were, I think, undoubtedly made, the companion being too faint for the smaller instrument. The distance is, therefore 66·502″, instead of that printed in the *Phil. Trans.* It is, of couse, almost needless to say that the measures of distance made with the 7ft. refractor are, on Sir John's own showing, quite unreliable. I am afraid that it will be necessary to take β.'s measures of 1878 as our starting point in any future investigations as to the motion of this triple. The *p.m.* of A seems to be small, Mü. gives only 0·041″ in 181·4°. I am not aware of any measures of ι^1 Libræ other than those quoted above; but if any reader of the English Mechanic has come across some, I hope he will communicate them.

Sept. 14. **H. S.**

DAYLIGHT OBSERVATION.

[21834.]—It may interest some of the possessors of limited optical means to know that stars as small as the third mag. may be very well seen in the daytime with an aperture of 2¼in. I once had a very fine view of Castor at due noon, with a telescope of that size, the two components of the star, respectively of the 3 and 3·5 mags., being perfectly easy to see, and apparently smaller and wider apart than at night, owing, I suppose, to the absence of surrounding glare in a light sky. My telescope having only a simple altazimuth mounting, I obtained this view by pointing the telescope at 11.25 on the preceding night to a part of the sky which included γ Lyræ in the field (this star having nearly the same declination as Castor), and leaving the telescope undisturbed until noon of the following day, at which time Castor entered the field, there being a difference of about 12h. 33m. of R.A. between the two stars. The power I used was 64. By the same plan—a most tiresome one in this climate, however—I obtained mid-day views of Polaris, Aldebaran, Sirius, Procyon, Pollux, Vega (very conspicuous), Deneb, Arcturus, and Betelgeuse. I saw the last-named star in a very transparent opening between clouds in rainy weather, and I have noted it down as a specially beautiful daylight object. Polaris, on one occasion, was so very distinct that I even tried to see the companion, but of course without success.

The same telescope also gave me a most exquisite view of the crescent of Venus at 4.30 in the afternoon of July 14, 1876, 6¼ hours after the planet's inferior conjunction. I have no doubt the crescent would have been visible to me at the moment of conjunction, but having to "fish" for it within six degrees of the sun, I failed to find it that time.

A small star in the field in daytime cannot be seen at once, as it would be at night, but has to be carefully looked for to detect it.

R. Y.

REPLIES TO QUERIES.

**** In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[51223.]—**G.W.R. Narrow Gauge.**—The stations of a few of the engines I inserted in Nos. 961 and 962, are as follows:—158, 159, 162, 165, 165, 166, 1117—1120, 1124—1126, 1128—1131, 2212—2215, 513—515, and 606, Paddington. 157, 160, 161, 164, 1116, 1121, 1127, 806, 807, 810, 1111, and 1429, Wolverhampton. 718, 721—723, 725, 726, 821, 598, 600, 601, 1087, 1092, 1094, 1099, and 1427 Birmingham. 1122, 1123, 811, 1106, 1108, 1109, 1114, 658, 664, 665, and 667, Gloucester. 383, 384, 387, 478, 480, 577, 580—584, 586, 430, 493, 501, and 389, Oxford. 379—381, 614, 625, 631, 632, 688, 1422, 1434, 1435 and 2201, Bristol. 385, 474, 479, 2202, 2204, 2205, and 2207, Swindon. 809, 814, 816, 818, 819, 824, 660, 661, and 687, Neath. 215, 517, 564, and 1424, Stourbridge. 717, 719, 720, 724, 621, 395, 509, 607, and 612, Cardiff. 545, 550, 555, 1431, 391, 402, 419, 425, 427, 512, and 1097, Worcester. 361, 398, 431, 595, 1439, and 1443, Hereford. 363—369, 1083, and 1110 Shrewsbury. 79—90, and 350—359, Pontypool-road. 378, 473, and 578, Birkenhead. 1186—1215 are mostly at Bristol, Paddington, Oxford, and Swindon, respectively. 1501—1560 are mostly at Wolverhampton. 1561—1656 are distributed between Bristol, Cardiff, Swindon, Aberdare, and a few other towns; but are mostly at Swindon and Aberdare. 1801—1812 are mostly at Wolverhampton. To give stations of the others would take too much space. I was mistaken before in saying that 69—76 are goods engines: they are 6ft. 6in. singles.—J. E. SPENCER.

[51229.]—**Dark Slide.**—To MR. LANCASTER.—Instructions for dark slides in another week or so: have been too much occupied to write before. Your filtered rainwater will answer every purpose, and for developing, if distilled water is not easily obtained, then put out basins, dishes, &c., and catch all the rain you can as it falls before going down a roof. If you are short of water, then you can temporarily use the hard water after boiling it for an hour.—W. J. LANCASTER.

[51231.]—**Gold Printing on Silk.**—I notice in your issue of the 7th inst. the reply of "C. T." to above query, which may be right enough for an amateur who desires to produce, perhaps, at most half a dozen copies; but as a means of printing neckties, &c., or even weaving the designs or names on them, your querist will find them in the "afternoon" in point of cost and speed. To do this, to be commercially successful, your querist will need a press and set of blocks or dies, to enable him to stamp about one gross per hour, the price he would get for his work ranging from 2s. 6d. upwards, according to size of design. Further information can be had if your querist will write as below.—FAULKNER, Denton.

[51253.]—**New Zealand.**—I should like to have "Imprimatur's" advice. I am forty-eight years of age; not strong, and unmarried. I should like to go to New Zealand, but could not work hard. I have been used all my life to small jobbing repairs of small houses. I have a capital of, say, £1,000. What could I do with this to bring in a living without much hard work? I could not tackle farming—I do not understand it, being a town-bred man.—OLD SUBSCRIBER.

[51253.]—**New Zealand.**—To "IMPRIMATUR."—I should be glad if you would give me some further information about this colony. What part do you think it would be best for an engine-fitter to go to—Otago or Auckland? I also want to know if a lady would be able to establish a private school for young children with success. Kindly say if New Zealand is considered more healthy than England—how it will suit neuralgic subjects. Can money be made building houses? I can do joinery work as well as fitting? What amount of interest can be got in safe investments for sums of about £200? Are clothes expensive in N. Z., and what clothes would you advise us to take? Are there any ways of occupying one's time on board ship by which I could prevent my hands getting soft, and as a means of making some little towards expenses—if I could make anything that could be sold on arrival? Any information that you can give will be a great favour to—ENGINEER.

[51274.]—**Overstrained Piano.**—In my reply last week it appeared that I gave £30 for a worthless piano, whereas the price should have been 30s. It is very likely the printer thought I had made a mistake, which was true enough, though not in the sense he intended. My object in stating the price was to prove how little value a cottage piano may represent, when it will not bear the tension of the strings, and to warn amateurs against too hastily concluding that such a piano must necessarily be worth the trouble and expense of repairs.—W. H. DAVIES.

[51274.]—**Overstrained Piano.**—I am glad to see a letter from Mr. Davies, who, I trust, will not feel offended if I point out that the cast-iron stays that he advises, though extremely useful in the higher treble, will not be of much service in the bass. If the backposts are really 3in. square, they are very badly designed, and the stays will not prevent some flexure or bending in the bass. What would in that case be really required is some front iron bracing in the bass, and one or two stays in the higher treble, as there is no room there for screws below the wrestplank bridge. I would strongly advise "P. Pianist" to try the screws first, and secure the bent side with some; this would be less trouble than the stays or iron bracing. If "P. Pianist" likes to advertise his address, I will lend him the number of "E. M." specially bearing on the defect of his piano, if he cannot obtain it from the office; it is at page 613, Vol. XIV.; and later on—if he find my screwing plan not sufficient—I would draw for him a plan and section of bracing. If the soundboard bars at the back are not unglued, the tone would not be injured, and I should think the soundboard would resume its proper shape and position from the downbearing of the wires.—J. C. L.

[51304.]—**Legal.**—This question is so complicated that it should be submitted to a solicitor with all the documents. If B. has not signed an agreement, he has *not*, and therefore cannot be bound by it, whatever he may be by any other document.—NUN. DOR.

[51313.]—**Power of a Wind Fan.**—This querist should say more distinctly what it is he wishes to learn.—T. P.

[51315.]—**Lighting Gas by Electricity.**—To MR. W. J. LANCASTER.—You should buy the steatite burners with the terminals already fitted; then connect them to wires from a Ruhmkorff coil, turn on the gas and then put coil in action, and the gas will instantly light. The whole thing is easily done: but it will be far better for you to buy the burners ready made than to attempt to make them.—W. J. LANCASTER.

[51315.]—**Lighting Gas by Electricity.**—This is done by passing a current through a platinum spiral, or by means of a spark between two platinum points. Probably the arrangement the querist saw was something like this: A magnet so placed as to pull the platinum coils over the burner when the current is passed, leaving them to fall back or be pulled back by a spring, when the current ceases, and the gas is alight.—S. M.

[51317.]—**Hand Punching Machine for Nuts.**—You want a hydraulic punching bear. There is one illustrated on p. 57, No. 931. Get some of the lists from the makers of these tools and you will find several designs.—ESSAR.

[51321.]—**Filter Beds.**—No material is fitted to be a permanent filtering medium; but it depends on more than "Antares" states what would be best to be done in his case. Is the 6ft. space already a brick-in-cement cistern, and has he an available supply of clean sand? If not, and the river will supply the tank by gravity, it would be cheapest to build a "canal" between river and tank and in grooves in the sides and bottom of "canal" slide stout frames, holding diaphragms of felt, which could be easily removed and cleaned as required. If gravel and sand are used, then it would be better to let the water flow on to the top of the gravel, and filtering through the sand, find its way into a central cistern of brick-in-cement by apertures at the bottom. The pump pipe enters this cistern, which is, in fact, a hollow cylinder of brick or iron stood in the centre of the filtering bed of sand and gravel. Should be allowed to stand dry one day a week.—NUN. DOR.

[51329.]—**Electro-Magnetic Machine.**—You will be unable to do anything with a magnet so small. It is altogether out of the question to obtain even a glimmer from a machine of such a size as your magnet would make. Carefully read all that you can about dynamos, and then make up your mind what to do. It is a pity to waste both time and money (for that is what you would do) if you attempted to build a dynamo with so small a magnet.—W. J. LANCASTER.

[51341.]—**Induction Coil.**—Your bobbin will answer for building a coil on, only it would be better to cut away the wooden tube altogether, and build up as follows:—*Core*: A bundle of wires making in all a core 9in. long and ¾in. in diameter, fasten the wooden discs, or what would be much better, two ebonite discs, at each end of the core: cover the core with one or two layers of paraffin paper. *Primary*: On to the core wind carefully two layers of 16 silk-covered wire, as close together as you can wind it; then bake the primary with solid paraffin in an oven for an hour, and insulate it from secondary with an ebonite tube $\frac{1}{16}$in. thick, or paraffin paper folded round and round until it is at least ⅛in. thick in the centre and $\frac{3}{16}$in. thick at each end. *Secondary*: Wind all the 36 on in successive layers, insulating between each layer with paraffin paper until all is wound; then you should again bake in paraffin. When finished you ought to get a 1¼in. spark with ease.—W. J. LANCASTER.

[51342.]—**Clarionet or Oboe.**—Please correct an error which appeared the week before last in my answer to "Woster." The sentence "There is 'one' mysterious wrinkle in the 'set' of a mouthpiece," should have read, "There is 'no' mysterious wrinkle," &c.—CLARION.

[51343.]—**Pens.**—"C. R. T." does not say of what his pen is made, nor describe the nature of the ink. Some steel pens are washed with a metal which protects them for a considerable time, even in the common iron-and-gall inks; but ordinary pens last a very long time with aniline inks. As "C. R. T." says his pen is "absolutely incorrodible," I suppose it must be gold, and therefore not much affected by anything likely to be used for ink.—NUN. DOR.

[51346.]—**Clarionet.**—In reply to "Vulcanite's" observations on page 42, I may state that in the first place $\frac{7}{16}$ was a mistake, as it should have read $\frac{5}{16}$, and that it would be as well if he would state "from what part of the reed he would measure the length of any clarionet." Also, whether he means to insinuate that a violin, an organ pipe, or the soundboard of any musical instrument, would be improved, or vice versa, if constructed of either cocoa (or cocus), of boxwood, or even of ebony. Finally, when he proves the defects of suitably selected spruce timber for resonant qualities, I will talk to him.—A., Liverpool.

[51346.]—**Clarionet.**—In reply to "Vulcanite," I do not mind what kind of clarionet I attempt to construct: just which you think best for an amateur. I think you will see that there is a great interest taken in these matters, and hope you will be so kind as to send article on "Tubes with Sounding Holes," which I suppose will include the question of nodes. With regard to kind of brass, I know so little about this instrument as to suppose the reed was of brass, which I now see is wrong. I entirely agree with the latter part of your reply, and hope you will enable myself and others to do so; and I think that practice should always be guided by theory as far as possible. In reply to "Clarion" about small F clarionet, Westrop, in his "Clarionet Tutor," says: "The small F clarionet is used in military bands, the sounds of which are a fourth above those written": which is all that I know about it. Thanks to "A., Liverpool," and others who have replied.—J. J. D.

[51346.]—**Clarionet.**—"Clarion," page 20, gives our readers no encouragement to make their own clarionets; he is afraid that those who attempt it "will not be very successful." Now, as I presume that most of our readers are either professional or amateur mechanics, I really see no reason why they should not make their own clarionets as well (for instance) as their own telescopes. My reason for saying this is, that I have tried, and succeeded, and when I began I was not a mechanic in any sense of the word, neither was I acquainted with theory. However, I was a player, and therefore knew a good instrument when I took hold of one, and having found one to my fancy, worked from it, and the result is a good instrument; therefore I say there is every hope of success for those who may wish to make their own clarionets. "A., Liverpool" (page 42), does not find that removing the bell sharpens any note whatever. Now, as I say it does sharpen the lower notes and their harmonics, I shall be glad if some third person will give his experience, and so prove to our readers which is right.—OLD BLOW HARD.

[51347.]—**Poultry.**—There are many books on poultry, from Wright's, published by Cassells, to one about sixpence, in which the author gives his method of making poultry pay. There are some books of the kind published at the *Bazaar* office, and a good deal of information in back volumes of this paper.—NUN. DOR.

[51353.]—**Brass.**—"Scotch Reader" might try copper 88, tin 10, zinc 2. A little lead might improve it. Much depends on the purity of the metal used, and on the skill of the melter. If small quantity only is wanted, better buy it of a good firm.—NUN. DOR.

[51356.]—**Vacuum Tube.**—Make a frame covered with black velvet, with pieces of elastic sewn on so that the tube can be placed under the elastic and be kept firm. The elastic should be as thin as you can get it, and black, so that it will not show. This is the simplest way of holding them, and one of the most effective I know of.—W. J. LANCASTER.

[51358.]—**Geological Exhibits.**—There are lots of lantern slides of geological subjects published. Write to some of the makers of lantern slides for their catalogues, and then select to suit your requirements.—W. J. LANCASTER.

[51397.]—**Motor.**—To MR. LANCASTER.—Don't bother with the Griscom. You will not have fall enough to work a water motor. The thing you can have is a one-man gas engine.—W. J. LANCASTER.

[51432.]—**Clarionet or Oboe.**—Having played these instruments alternately for the last dozen years, I venture to reply to this query. The oboe is distressing to ordinary players, as it is quite impossible to expire entirely through it, so one has to partly inhale and exhale, independent of the instrument. Very few, even professional players, can do this with comfort. The clarionet, on the other hand, will take as much wind as one likes to give it, so that, with a suitable mouthpiece, no distress is felt, and the performer requires to inhale only. I believe the oboe is not good for the health, and doubt if it strengthens the chest for the above reasons. As to the clarionet, I never had a cold in my chest above a day since I commenced to play, the general opinion being that the oboe is bad unless played from the chest and throat, like Mons. Lavigne, Reynolds, and one or two others. It is done the same as an ordinary chemical blowpipe, the difficulty being that it takes far more air than an ordinary blowpipe.—VULCANITE.

[51447.]—**Switch for Lamp.**—From what I understand of your query, I infer that you either use the current for lamp, or you short-circuit, letting the current really waste. This is wrong altogether. Each time you cut the lamp out of circuit you should so arrange that the current is broken: then there will be no waste, and you will have best effect.—W. J. LANCASTER.

[51455.]—**L. and N.W. Locos.**—2453 is a coal engine (Webb) with cylinders 17 by 24, six-coupled wheels 4ft. 3in. in diam., and weighs between 29 and 33 tons. 2455—2457 are Mr. Webb's 4-wheel shunting tanks, with dome and chimney combined, footplate at either end, firebox fitted with water-tube firegrate, Allan's straight link. The following are chief dimensions:—

Diameter of cylinder	9in.	
Stroke of piston............	12in.	
Diameter of wheels	2ft. 6in.	
Total wheel base	5ft. 6in.	
No. of tubes (120) out. dia..	1⅝in.	
Length of tubes between tube plates	3ft. 6in.	
Total heating surface	257·86 sq. ft.	
Firegrate area	5·47 sq. ft.	
Capacity of tanks (below footplates)	260 gals.	
Weight of engine roadworthy:—		
	tons.	cwt.
Leading wheels	7	11
Driving wheels	7	12
	15	3

Several engines of this class do shunting in Crewe Works Yard.—TITTESWORTH.

[51475.]—**Coil.**—Three layers for primary are ample; in fact, two layers, well wound, are almost sufficient. But in the coil you are making, three layers will do well, and you would lose by putting four layers. You must have as nearly perfect insulation as you can possibly get, to make your coil give its full work. This, of course, you know, and the importance of winding the secondary as smoothly as a reel of cotton.—W. J. LANCASTER.

[51484.]—**Reed Organ.**—"Organon" recommends me to build a pipe organ if I wish to go beyond 2 man. and ped. The reed instrument would not be tolerated were the former practicable, which it is not, on account of space, power, and cost. I do not quite see why pipes cannot be tuned to reeds. To Mr. FRYER.—The 20 rows would be of 5 octaves each, and do not include ped. reeds (say 4 sets of 30 notes). Couplers reqd.: man. to man. (3), ped. to man. (3). Number of sets on each man. undecided; should like advice and brief specification: 8ft. tone must predominate, not more than 2 (or 3) 16ft. reeds on manuals, and 3 (or 2) 16ft., with 1 (or 2) 32ft. on ped. What size bellows and reservoir (on equal-pressure principle) would be required for above, and what pressure upon reservoir?—G. MINOR.

[51497.]—**Small Brace.**—I have seen several answers to the above query, besides many sketches of drills. But they are all useless for the purpose required (that is, if 25 years' experience is any authority). What E. Owen requires is a drill stock, breastplate and bow, what is termed a fiddle drill, and the drill must be a diamond one, the same as is used by all china restorers. The best metal to set the diamond in is thick copper wire. Setting them in tubes is an old and clumsy mode of setting them not used by anyone in the trade. There have been many answers given to similar queries by persons who could have had no knowledge of the subject.—B. A. C.

[51500.]—**Mathematics.**—Hoping "Poor Labourer" will not find himself puzzled by the number of replies to his question, I venture to add one more. In integrating, as J. F. Wilkinson has done, if symbols are put instead of figures, the rule comes out thus: Let a and b = length and breadth of the base, c and f = length and breadth of the top, also h = height, then the contents = $\frac{h}{6}(2 . a . b + 2 c . f + a . f + b . c)$, that is, twice the area of the base, added to twice area of the top, added to length of base multiplied by breadth of top, added to breadth of base multiplied by length of top; the sum of all this multiplied by one-sixth the height. If c or f be made = 0, then the rule becomes that of a heap whose top is a line, and if c and f both = 0 the rule is of a pyramid. Applying the rule to the cases required, 1st, let $a = 11$, $b = 10$, $c = 5$, $f = 5$, $h = 5$

$$\begin{array}{rrl} \text{then } 2 . a . b = & 2 \times 11 \times 10 = & 220 \\ 2 . c . f = & 2 \times 5 \times 5 = & 50 \\ a . f = & 11 \times 5 = & 55 \\ b . c = & 10 \times 5 = & 50 \\ \hline & & 375 \times \frac{5}{6} = 312{\cdot}5 \end{array}$$

2nd. Let $a = 20$, $b = 10$, $c = 15$, $f = 5$, $h = 5$.

$$\begin{array}{rrl} 2 . a . b = & 2 \times 20 \times 10 = & 400 \\ 2 . c . f = & 2 \times 15 \times 5 = & 150 \\ a . f = & 20 \times 5 = & 100 \\ b . c = & 10 \times 15 = & 150 \\ \hline & & 800 \times \frac{5}{6} = 666{\cdot}\frac{2}{3} \end{array}$$

The extraction of the square root is avoided by this rule.—FRANCIS MARTIN.

[51532.]—**Stern-Wheel Steamers.**—If "Anton" will get *Engineering* for Friday, Sept. 7th, and refer to page XL. of the advertisement sheets at the end of same, he will find a good illustration of a stern-wheel steamer, which may be of service to him.—KERAULOPHON.

[51540.]—**To Mr. Lancaster.—Solar Spectrum Photographing.**—You may alter the size of image considerably by using a shallow concave just in front of the Méritoire lens. Thus, a 48in. concave will make the lens 1in. longer in focus, and a 24in. will make it more than 2in. longer in focus, in each case giving a proportionately larger image on ground glass. By altering the position of the concave, you will also vary the size of the image. It is an easy matter to enlarge the small negative you have already obtained; but I think it is worth the trouble of a few experiments to get a good photo.—W. J. LANCASTER.

[51544.]—**Induction Coil.**—Three layers will be quite sufficient for your coil. If you will read answer No. 51341, and then if you want further information, write another query, I shall be pleased to help you.—W. J. LANCASTER.

[51545.]—**Rust on Hairsprings.**—I must apologise to "A Fellow Workman" for the delay in replying to his query; it has been unavoidable. Respecting the appearance of rust upon hairsprings after they have been immersed in acid to weaken them, I imagine that they were not sufficiently cleansed in the afterbath, if you used one. If you omitted to remove all traces of acid by immersion in spirits of wine, or other liquid, then the rust may easily be accounted for. If you have taken every known precaution against the formation of rust, then I should say the appearance of rust afterwards is accidental, caused by exposure to damp in one form or another. The colour produced by oxidisation upon the metal is a preservative from rust, and as the act of immersion in acid tends to destroy and remove that colour, some preventive must be adopted, and I know of no better than to dab the spring with paper, or something ever so slightly moistened with clean oil. I am sorry I cannot give you an absolute rule as regards the sizing of barrels, springs, and balances when either are absent from watches. No doubt actual manufacturers have certain well-defined lines upon which to work in laying out or planning watches; but I am not a manufacturer, and in replacing a lost balance, barrel, or spring, I should be guided more by knowledge and common sense than by rule or theory. After many years of practice in the work, one gets almost intuitively to know what kind, length, or strength of spring: what size barrel, balance, or missing wheel such and such watches require, without depending in any way upon set rules. When a wheel is lost, of course, the train numbers must be ascertained, as it would never do to take any wheel that happened to be the right size unless the number of teeth and pinions corresponded with the lost one. For instance: Supposing a centre wheel with a pinion of 10 and 57 teeth was set in a watch from which a wheel having a pinion of 12 and 54 teeth had been lost, no correct timekeeping, even if the watch went well, could possibly be got out of it.—ALFOJOE.

[51556.]—**Chemical.**—The substance mentioned in the first part of this query is probably silica; if so, it would be insoluble, when heated before the blowpipe in microcosmic salt; it would dissolve with effervescence, when heated with excess of sodium carbonate, forming a clear glass, which is soluble in water, and from which solution dilute HCl would precipitate the silica in a gelatinous form. The oxides of the rarer metals combine with alkalies when heated with them, forming an *opaque* mass, from a solution of which acids throw down the oxides, but the precipitates thus formed are soluble in microcosmic salt, when treated as above; they may be dissolved in HCl, and treated with zinc as below. The blue powder may be fused with $KHSO_4$, dissolved in water acidulated with HCl, and a strip of metallic zinc placed in it. If molybdic acid is present, the solution turns colour, first blue, then green, and finally dark brown; if tungstic acid, blue, then copper-red; if vanadic acid, blue, green, lastly violet; if titanic acid, violet. "A. E. S." will find the blowpipe the easiest means of detecting these metals.—W. E. HADEN.

[51557.]—**Nickel Plating.**—Thanks to "E. A. H." for his answer to my query. I see Gore mentions similar solutions. I have not tried them yet, but intend doing so, as "E. A. H." recommends them. May I ask what proportions he recommends to make one gallon of solution; also, the ammonia nickel being liquid, how shall I determine the proper volume of bisulphite being a solid. Now, as to batteries, I have no bichromate cells, but if the result would prove more satisfactory, I would construct some. What size should they be each, the surface of zinc exposed and relative proportion of carbon surface to get the most out of them? Also how often do they require recharging? Will commercial nitric acid do for dissolving nickel, or should I use pure. I find the former dissolves it more rapidly (what is the dark red gas evolved?) Is it necessary to crystallise before using? I find the crystals liquefy on being brought into a warm place. Is this right? Since writing my original query, I have deposited from a solution of nickel and ammonia. The deposit is firm and regular, but of rather a dark colour. How could I make it whiter from this solution, as I have a quantity of sulphate which I wish to utilise. Can "E. A. H." or any other reader tell me how to get the high polish on nickel-plated articles, which we find on bought goods. Details of the process will oblige. What appearance should goods present on coming out of the bath? The name of some recently published book, treating on the whole subject (if such exist) will oblige—ONE STILL IN A DIFFICULTY.

[51560.]—**Atomic Theory.**—The mechanical theory considers atoms in relation to physical forces only, and has no regard to the composition of the atom. Thus, according to this theory, an atom is the ultimate particle or unit of matter; yet this atom, as it is termed, may contain two or more chemical atoms. Take for example the common mineral—sulphide of copper; an atom of it will contain both copper and sulphur in the proportion of 63 parts by weight of copper to 32 of sulphur. Here we see the physical atom contains two chemical atoms of unequal weights. Such examples are almost unlimited. The atomic theories are simply theories, as it is quite beyond our power to ascertain the absolute condition of the ultimate particles of matter. No physical power we possess can enlighten us as to how the copper and the sulphur are combined together in the sulphide. No particles of the separate elements can be detected by the highest power of the microscope, while the compound of the two elements is entirely different in physical properties from either of its constituents. Therefore, we can only suppose they are united together in what we term atoms, the definition of an atom being "the smallest particle of a body, which undergoes no farther division in chemical metamorphoses." From the fact that in sulphide of copper, the copper and sulphur being always found in the proportions above named, we can reasonably infer that the relative weights of the atoms are 63 and 32. A chemical atom differs also from a physical one, in being the centre of a great attractive force, which is termed "chemical affinity." This affinity is not of the same intensity between all atoms. In conclusion, the physical atom corresponds to the chemical "molecule," which is a combination of two or more atoms, far more than to the chemical atom, especially as the latter is supposed to be incapable of existing in the free state, but must unite with another atom to form a molecule, as appears evident from chemical reactions. One can hardly expect the two theories to coincide exactly, as they are put forward to explain very different phenomena.—W. E. HADEN.

[51563.]—**Shaft.**—Your shaft will break with a load of about 250cwt. If the arms are arranged symmetrically round it, they, and the weights they carry, may be taken as dead load.—GLATTON.

[51565.]—**Photographic Printing.**—Please give the recipe you mention.—P. C. W.

[51568.]—**The Audiphone.**—If your correspondent is so very deaf that he cannot carry on a conversation with friends when speaking close to him, and his deafness does not arise from the auditory nerve being affected, there are various little plans by which he may be assisted if he has sound upper teeth, and I will mention two or three if you think them of sufficient value to give them pubfamilies from compulsory vaccination. Not only so; they are forced upon them. Before we had vaccination as by law established none were found to complain of the results; but since it was compulsory the mixed up manner in which the operation is often performed brings many complainants. Had the compulsion been confined to a family or neighbourhood suffering from small-pox all purposes would have been met, and the arbitrary character of the enactment avoided. "W. M.'s" doctor says of his child's case that "it is nothing, and will go off." We may suppose, like a gun, loaded or unloaded. Skin complaints inoculated with vaccine are difficult of cure.—VACCINATOR.

[51633.]—**Boot-Sewing Machine.**—Perhaps the presser foot spring is not strong enough. Put more pressure on foot and raise feed-teeth up very slightly, tighten the shuttle tension and then the top until it pulls locking of stitch well between the leathers. You can do this until the threads will not stand it and will break; if they do, you must slacken again. Have you got an awl-pointed needle? If not, get one, and you will most likely succeed after following the above.—J. I. S.

[51634.]—**Cleaning Stove Pipe.**—A piece of zinc thrown on the fire is said to effectually clean a stove pipe by chemical decomposition of the soot. —H.

[51634.]—**Cleaning Stove Pipe.**—The "substance" you wish to know the name of is ordinary zinc. I have not tried it myself, but I hear that on putting some of the metal on the fire the soot up the pipe disappears like magic.—R. A. R. BENNETT.

[51634.]—**Cleaning Stove Pipes.**—Your stove must be badly arranged to make so much soot (wants more air amongst the fuel). Think the substance inquired for is the old housewife's remedy—viz., a small quantity of gunpowder.—A., Liverpool.

[51635.]—**Photography.**—The blistering of the prints is more likely owing to the lighter sp. gr. of the water than to its impregnation with air. Try the effect of some common washing soda in your fixing bath, say 1 oz. to the pint of solution. This makes the paper more porous, and much less liable to blister than otherwise. If that does not answer, you might increase the density of the wash-water by throwing in a handful or two of common salt.—W. ROBINSON, JUN.

[51638.]—**Lathe.**—You had better get the parts turned and bored, if you have not a lathe. You cannot melt gunmetal in a wrought ladle, you can melt tin. I have a 4½in. back-geared lathe, the spindle of which runs in tin bearings.—W. W. EVERS.

[51641.]—**Seaweeds.**—Wash the seaweeds in a basin of salt water, and then float them singly in a dish of fresh water; push a piece of cartridge paper under the seaweed, and draw it out of the water, arranging it with a camel's hair brush, the handle of which should be finely pointed for separating the finer fronds. Cover the seaweed with a dry rag, and place it between several pieces of blotting-paper, and put it under a weight. The rags and blotting-paper should be changed every day, till the seaweed is quite dry. Thick seaweeds that will not readily adhere to the cartridge paper, should be floated in a dish of skimmed milk (instead of fresh water), and treated in the same way as the above.—E. F. B.

[51642.]—**To Mr. Lancaster.**—There is not any royal road to success in determining exposures; it is simply resolvable into two words—"Experience teaches," and to gain this experience you must be methodical. Make a note of every exposure—subject, time of the day, amount of light, and length of exposure. You will soon become proficient, and no longer will over-exposure trouble you. Besides this, as much care is necessary in developing. You can do wonders with the developer when you know how, and you must be your own tutor. The best workers have all had the same training.—W. J. LANCASTER.

[51644.] — **Model Boiler.** — Use methylated spirits of wine, either with or without wick.—P. C. W.

[51644.] — **Model Boiler.**—Try methylated spirit, or fit a small blast-pipe in chimney, the hole in pipe nozzle to be size of a pin.—W. W. EVERS.

[51644.]—**Model Boiler.**—You will, I opine, find that you can get sufficient draught for charcoal if there is no obstacle to prevent the lengthening of your chimney.—A., Liverpool.

[51655.] — **Signal Boxes.** — The diamond-shaped pieces of wood or tin painted white attached to signal-boxes indicate that the telegraphic instruments in the box are in proper working order. Should any failure or hitch occur to the instruments, these signs are reversed, the other side being coloured black, and this gives notice that repairs are required to those engaged in the telegraphic department.—W. H. Y. T.

[51655.] — **Signal Boxes.** — The presence of these white boards outside signal-boxes informs the telegraph and signal fitters that the apparatus under their charge is in good working order and repair, I believe. T, of course, means "telegraph," and S, as seen on the North Staffordshire Railway, stands for "signals," I suppose. On this line the diamond-shaped board is the telegraph and the oval the signal notice, and I think this is usually the case. I have always understood that the above is the use of these boards, and that an answer to this effect was given some years ago with especial reference to the G. E. R.—TITTESWORTH.

[51655.]—**Signal Boxes.**—The diamond and oval-shaped pieces of wood painted white, which are exhibited outside many signal-boxes, are for the purpose of informing the drivers and guards of passing trains that the telegraph communication and all signals in the box are in good working order. The other sides of these boards are painted red, and when this side is exhibited, it signifies that something is out of order in the box, affecting the ordinary system of signalling the trains. On some lines where these boards are not used (as on the L. and S.-W. R.), the telegraph being out of order is denoted by the exhibition of a small black board, and the signals by a red board; the absence of anything showing that all is in good order.—MACHINA.

[51655.]—**Signal Boxes.**—The North-Western signal boxes are provided by the telegraph and signal departments with oval and diamond-shaped boards respectively. The ovals are painted white one side and black the reverse. The diamonds are white and red. If the telegraph instruments and signals are in good order, the white sides are exhibited; but should any defect occur then the oval or diamond board (as the case may be) is reversed. The object in doing so is to get the attention of the men belonging to either department who may go by in a train, and who keep a sharp look out for such evidence of any defect. It thus frequently saves valuable time over simply reporting a fault to headquarters by wire or letter. Possibly on some lines both sides of the boards are painted alike; but on one side is the initial T for turned. The object is the same.—TRAFFIC.

[51656.] — **G.W. Engines.**—I am unable to answer either of "W. B. P.'s" questions under this heading, but would remark the presence and ask the signification of the two horizontal white diamonds on most of the goods waggons, brakes, and vans on the L. and N.W. Railway? A large white diamond is painted on the trailing wind screen of the metropolitan bogie tanks on this line, a flat diamond-shaped piece of metal being hung on the disc rings of the chimney.—TITTESWORTH.

[51658.]—**Light.**—You will find full instructions and diagrams in Profs. Mayer and Barnard's little book on "Light," published by Macmillan in their "Nature Series," 2s. 6d.—C. WALTER HEPWORTH.

[51659.]—**A Three-Cell Battery.**—"Physis" requires instructions how to make a three-cell battery as efficient as possible. The inquiry is very indefinite; perhaps the following information will be somewhere about what he wants. In order to obtain the greatest amount of power with the least weight and bulk, Grove's platinum battery is the best, but the use of nitric acid is so objectionable that in most cases it is better to employ a bichromate with strong acid solution. If, however, the greatest efficiency for the amount of acid and battery materials consumed is necessary, then a Bunsen battery with dilute nitric acid and weak sulphuric-acid solution is the most economical, but the weight of the battery has to be very much increased in order to equal the quantity of electricity given by a stronger acid. A sulphate or oxide of copper battery is both more expensive to work and less efficient as regards bulk and weight than the above; but in cases where there is occasion for constancy, it is perhaps as efficient as possible, and all other batteries have qualities which cause them to be used at times. "Physis" had better say what purpose the three-cell battery is wanted for if he requires instructions to make one.—J. SUTCLIFFE.

[51662.]—**Iron Developer for Dry Plates.**—Make saturated solutions of protosulphate of iron and oxalate of potash: then, supposing you wish to develop a quarter-plate, take 2dr. of the former and pour the latter into it until the muddy precipitate first formed is redissolved, the result being a clear solution of a deep orange red colour. Then flow over the plate, adding a little water if necessary to make up the bulk. This will soon bring out the image on the surface of the plate; but a rather prolonged immersion, say a quarter of an hour, or more, is generally requisite to bring the plate up to full printing density; and this you must judge of by holding the plate up against the light and by examining the back, which will be more or less discoloured if the developer has penetrated right through the film. Supposing full density to have been acquired, nothing more is necessary to insure the purity of the whites in printing. In the case of weak negatives various dodges are resorted to, such, for instance, as coating the back of the plate with coloured varnish, and scraping away those parts where the light is required to penetrate deeply. In the case of portrait negatives, where probably little more than the face requires protecting, a good plan is to stipple over the back with a little oil-colour Prussian blue. All "dodging," however, of this description requires considerable practical experience for its proper carrying out; therefore, do not rely upon it, but always, if possible, obtain full printing density in the ordinary way. If you cannot succeed with ferrous oxalate, try pyro.—W. ROBINSON, JUN.

[51666.] — **Cutting Keyways.** — "When one key is employed, its breadth should not be less than ¼ of the diameter of the shaft, thickness equal ⅔ of the breadth, and taper for large shafts ⅛in. in 18in. When three keys are employed, the breadth is ⅙ or ⅕ of the diameter of the shaft, and thickness ⅔ of the breadth." From Binn's "Orthographic Projection."—J. J. D.

[51671.]—**Chimney Flues.**—If the chimney was larger at top than bottom, there would be less friction between the gases and sooty sides of chimney, which is given by Wilson and others as 0·012 in an ordinary chimney; the gases in the chimney cool as they ascend, and move at a slower rate, thus having to be partly forced out of chimney top by difference in weight of atmosphere and heated gases at bottom. If chimney is larger at top the slower rate is taken up by larger area, thus forming no impediment to progress of hotter gases below; but the stability of chimney must be considered. Although chimneys have been built parallel inside and parallel outside, with batter of brickwork inside (none of very large size have been so built), I have never heard of any advantage having been gained; if there was any practical advantage in so having them built, no doubt there would be more in existence than at present.—BOSWELL.

[51673.]—**Bee-Keeping.**—Cut a hole in top of skep, and fit a piece of perforated zinc into, or on to, it, *quite level*; on this put a piece of tin, or zinc, with six or eight fine bradawl holes in, close together. Make syrup of 5lb. sugar, *raw*, to 1qt. water, just to boil. Fill a honey or pickle bottle, and invert this on to tin with holes in. Refill as often as empty. As time is getting short now, a better plan would be to unite them to another stock, if you have any. Write again if you require further information.—J. I. S.

[51674.] — **Decomposition of Water by Electric Current.**—Water may be decomposed by a current from two Bunsen cells, quart size, or by two of Grove's cells (pints). The current from two Bunsens (quarts) is strong enough, and the cost is much less. Bunsen quart cells are about 5s. 6d. each, while Grove pints cost 10s.—W. A. FELTON.

[51674.]—**Decomposition of Water by Electric Current.**—The strength of current is in proportion to the size and number of the battery elements, and also to the resistance of the water to decomposition: when the water is acidified it conducts better, and a stronger current passes. A battery of any kind or size will do for the experiment if it has sufficient electromotive force. Twelve copper or zinc couples, plates 3in. square, six cells, Daniells, or three Bunsens, will be enough; double these numbers are better, as the gases are given off more rapidly. You should make slips of platinum foil ½in. wide and ¾ to 1½in. long, smaller or larger, according to the size of your battery cells. The slips must be soldered to copper wires, then heat them hot enough to melt sealingwax, with which you must cover the soldered joining, and all the wire that is to be immersed. When the platinum pieces are put into the acidulated water within a short distance of each other and connected with the battery, the water will be decomposed.—J. SUTCLIFFE.

[51675.]—**Disinfecting Pictures, &c.**—Any movables, if taken into the open air and well blown on with the kitchen bellows, will be more naturally disinfected than by any method prescribed by the chemist.—T. P.

[51678.]—**Stinking Indiarubber Gaspipe.**—There is no remedy; the rubber is being attacked, and the destruction will go on until the pipe, as a pipe, is spoilt. You should procure the special tube employed for gasfittings. It is covered with several layers of cotton or linen and well varnished. —NUN. DOR.

[51680.]—**Surveying.** — The instructions for measuring the land will, I fear, take too much space for these columns. Hayricks: Take the mean length and width of rick in feet at half the distance from base to the bond above the eaves, and the mean height from base (not ground) to the aforesaid bond; then multiply length by width, the sum by the height, and divide by 27; the result is cubic yards. You must then judge the solidity—i.e., how many cwt. to a square yard; a hard rick has about [illegible], a new rick about 1, to the cubic yards above, say, 60. Add the solidity say at 1½ = 60 + 30 [illegible] 90 [illegible] 20 (i.e., 20cwt.), the result is tons of hay. Or, instead of [illegible] by 27, by 400; the quotient will be loads, the remainder trusses. (A truss of old hay weighs 56lb. new 60lb.) And, if the loads are multiplied by [illegible] trusses in a load) you find about the trusses. The trusses may be found exactly by reduction of content, and dividing by 56 or 60. The foregoing is the plan used by the professional valuer: the following is, I believe, used by many farmers. Instead of dividing by 27, divide the sum by 54 if the solidity is 1cwt.; by 432 if 1¼; by [illegible] if 1½; by 308½ if 1¾, and so on; the quotient is tons. Straw: four-sided ricks as hay. Round stacks: Multiply circumference by diameter, and ÷ by 4; multiply this by height (to eaves). The circumference should be the mean, and the diameter is ⅓ of circumference. And for the roof: Half the circumference under the eaves × half diameter × half height of roof ÷ 3 = contents of roof; add content of stack, and reduce to tons as for hay. Or, half circumference of stack × ½ diam. × by height = content of stack without roof.—H. Hannen.

[51683.]—**Kidney Beans.**—We have repeatedly and without failure preserved beans in the manner indicated by "Kanet." We have just put some down for winter use. Did "Kanet" shred the beans, or were they put in whole? We shred them as for boiling, put in jar, layer of salt, then layer of beans, and so on till sufficient are laid by for winter use. Ours have come out perfectly green and good, and when soaked overnight in water to extract salt, can scarcely be detected from perfectly fresh beans.—[illegible]

[5168[illegible].]—**The Other Side of the Moon.**—Modern science will always be exposed to the badinage of such queries as "W. G. C." till it gives us some more intelligible information upon those special subjects it professes to deal with. Nothing of a reliable nature has yet been furnished us with respect to this luminary. And the same equivocal testimony is all we get from scientists in general. Why should not the moon have a dark as well as a bright side? We see the bright side without any glasses, and with them we can often discern the whole circle, even when she is in her first quarter. If anyone will take the trouble to paint a child's ball half white or black, and slowly turn it round, they will see all the moon's changes very plainly illustrated. The centre of gravity being "eight miles" nearer one side or another, I leave to those who have taken the measure of it. I should not wonder if they were a few yards out.—John Haw[illegible].

[illegible] **Historical.** The exact date is quite uncertain, but there is little doubt it was introduced during the Apostolic age, probably from [illegible] A.D.—W. Robinson[illegible].

[illegible] **Historical.** Haydn's "Dictionary of Dates" states, [illegible] Bede as an authority, that Christianity was taught in Britain about A.D. [illegible], and with success [illegible]. Green and Haydn agree that Augustine landed in [illegible].—[illegible]

[illegible] **Historical.** Gildas, the earliest British historian, says that the religion of Jesus [illegible] at the time of the [illegible] the Romans [illegible] Saltmarsh's [illegible] Church," page [illegible] Chronology," gives the [illegible]

[illegible] **Historical.** In [illegible] A.D. Columba founded [illegible] the Island of Iona, one of the Hebrides, with a chosen band of twelve, who accompanied him from Ireland, whence he came. Columba [illegible] took up his residence with King Brude [illegible] one of the most [illegible], and while there met with a petty prince of the Orkneys, [illegible] an opportunity. By his means [illegible] sent his disciples to the extreme North, and introducing Christianity to the [illegible] then known world.—[illegible]

[illegible] **Photography.** [illegible] "P. C. W." [illegible] "Paget" bromo-gelatine dry plate [illegible] any amount of density he may require. Plates may be intensified with solution of bichloride of mercury followed by a weak solution of ammonia. Nothing can be done in the way of toning a plate after it has been exposed and fixed. The toning bath is good, but the addition of soda is not required after the first quantity. The black deposit indicates a reduction of the gold in the toning bath. I fear "P. C. W." is not careful in using each vessel solely for the one purpose. Does he keep his fingers clean?—[illegible]

[illegible] **Tennis Court.** Pick up the old concrete to the depth of about 2in., and relay with *concrete mixed as follows: Fine sea shingle 3 parts, Portland cement 1 part. If this is put on not 2in. thick, I do not think you will want anything better.*—[illegible]

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list and send what information they can for the benefit of their fellow contributors.

QUERIES.

[illegible]—**Pot-Pourri.**—Can any of your readers oblige me with a recipe for pot-pourri?—H. A. C.

[illegible]—**Royal Arms.**—To Mr. Wetherfield.—Under the new Patent Law, what authority is requisite for the use of Royal Arms, and how obtained? Does the penalty apply to designs in use already, and would informers get any portion? There must be an enormous number of cases where people have labels used for years in stock—very often hundreds of pounds worth—with no written authority procurable, but only a traditionary evidence of supply to Royalty. How will the Act affect such? A reply at earliest convenience will be, I doubt not, a boon to many, as it certainly will to—[illegible]

[illegible]—**Crystoleum Process.**—I have followed out the directions given by your correspondent for painting photographs by the crystoleum process; but find that after a short time they are covered with unsightly spots and patches, and are thereby utterly destroyed in appearance. Is this caused by some defect in the photograph, or in my method of applying materials, or something wrong with the latter? I may state that I have substituted poppy oil for that mentioned in the directions.—[illegible]

[illegible]—**An Excellent Yeast.**—In the English Mechanic of a week or two back I cannot give the exact date appeared a recipe under the above heading, which consists of [illegible] of hops, 1lb. of brown sugar, ¼lb. of flour, a small handful of salt, and 3lb. of raw potatoes, with four quarts of water; and as I am anxious to know of something which will serve as a substitute for the ordinary publicans' barm, that is chiefly used in this neighbourhood, and is often very scarce, and sometimes miserable stuff, I decided to make up and try the above recipe, but the results have been very unsatisfactory; but perhaps the failure was due to the imperfect manner of my carrying out some of the smaller details. In the first place I used what is called the best batch flour, and perhaps I should not have used that sort, and I kept it in a saucepan with the lid on by the side of the fire—which might have been wrong also; and further, I tried it in the same way that ordinary publicans' barm is generally used. But whatever might be the cause, it certainly in its present condition is quite useless. Will the author of the above recipe, or any other kind friend, help me out of my difficulty, and oblige?—E. R. D.

[illegible] **Centre Board.**—I have a 15ft. punt, which is kept on the beach near the sea. Now the beam being [illegible], she has not enough depth of keel to sail well. The keel is about 3in. thick and 4in. deep, with iron all along the bottom. I should like to make a centre-board, lee-board, or something to answer that purpose. It might be fixed and unfixed when the boat is in the water. I have some objections to a centre-board to go right through the keel from the inside in the usual way. If any one would kindly give me a hint, it would greatly oblige—[illegible]

[illegible] **Smoke Nuisance.**—Can any one tell me if there is any way of stopping the black smoke that rolls out of large stacks that several fires run into? Also if there is an apparatus by which you can consume your own smoke?—[illegible]

[illegible] **Levelling Slab for Toning Prints.**—Will any of "ours" kindly instruct me how to make a levelling slab of a simple kind, such as is used by photographers in toning prints?—Tyro.

[51702.] **To "The Kent Hermit."**—On p. 488, last volume, you state that "kind Providence has planted in our gardens a vegetable which will cure every known disease." So far, only the readers of "ours" who are invalids have applied for the information which you so kindly offer. Might I ask you for the information on behalf of those who take an interest in botany (and they must be numerous amongst the readers of the "E. M.")? After carefully watching your replies up to date, I have, in a botanical sense, only noticed one recipe, and that is that asparagus cures rheumatism—Wm. Cowan.

[51703.]—**Arithmetical.**—Would some kind reader solve the following?—A train 635ft. in length running at the rate of 45 miles, overtakes another 565ft. in length, running at the rate of 40 miles. In what time will they be clear of each other, supposing they are running on parallel straight lines?—E. M. H.

[51704.]—**Problem.**—A. and B. built a wall 100 yards in length for C., who paid B. 2s. per yard more than he paid A. C. paid each £50. How much of the wall did each build, and at what rate per yard? Formula wanted such that the answers may be carried to any desired no. of decimals.—Neglected Education.

[51705.]—**Sundial on a Card.**—I have made many of these dials, but have never been able to find out the principle on which the lines are laid down. Can any one or your scientific readers assist me?—G. Roberts.

[51706.]—**Model Boiler.**—I am making a small model horizontal engine—dia. 1in., stroke 2in. Will one of our contributors give me dimensions of a good substantial boiler to work the same?—Nonplus.

[51707.]—**Texas.**—As I am thinking of going out to the State of Texas in a short time, I would feel favoured if any of "ours" would give a general description of the country: such as the climate, people, work to be had, and probable chance of success in life with settling down there latterly? I can get a shepherd's situation there from an acquaintance of my own. I would be about 80 miles from Austin, the chief town, and 200 miles off the sea-coast. I have no money. Is the heat oppressive? How much wool would I get off 100 sheep per year, and what is it worth there? What is the value of 20s. there in contrast to 20s. here in Scotland?—Shepherd.

[51708.]—**Restoring Ink Writing.**—Can any chemist or other among your readers kindly tell me how to restore ink writing that has been bleached and rendered invisible by a fluid apparently a solution of chloride of lime. The fluid is colourless, and about the consistency of glycerine.—W. F. L. Low.

[51709.]—**Telephone Transmitter.**—To Mr. R. W. Hart.—I have an electric bell from my house to place of business. Can I use the same wires, &c., for a telephone by using the transmitter described in 21770 last week? If so, I shall be glad to know where to obtain the carbon necessary. I shall be pleased to give the result of my experiment in the "E. M."—Fred.

[51710.]—**Electric Bells.**—I want more battery power for my electric bells. I have been using one of the old form of the Leclanché with porous cell. Would it answer if I were to add one of the patent Leclanchés to it? If so, must it be same size cell? Also what makes the zincs get so black?—V. M.

[51711.]—**Greenhouse Valves for Hot-Water Pipes.**—In a greenhouse divided into three parts—say A, B, C—the boiler to be placed near where A B join, which is the best plan of heating?—(1) To have separate flowpipes and returns for A and for B C, or (2) to have only one flowpipe and work the other two divisions therefrom? Also, where must the valves be placed so as to heat A only, or A B only? If only one valve at each shut-off, is it on flowpipe or junction, or are two valves necessary at each shut-off?—C. Gravenhall.

[51712.]—**Stone - Setting.**—Will some jeweller kindly give some hints on setting and resetting pearls and stones in rings and other articles of jewellery—such as how to make the minute claws that hold the stone, and how to sink the edge of the hole in the form of a rebate to take the stone? The settings I mean are like a bright star cut in the surface of the ring, and the stone appears to be held by minute claws in the points of the star.—J. E. A.

[51713.]—**Padding Flute.**—I play a Carte-Boehm flute. Sometimes when the pads on valves get worn, and there is a leakage, I have a difficulty in finding out where the defective pads are. Could some reader direct me how best to discover where the leakage occurs? In putting on a new pad, I frequently make it either too thick or too thin. Can I tell the thickness of pad to put on by any other means than by experimenting?—Amateur.

[51714.]—**Removing Ink.**—I have some fine hand-painted gelatine cards. There is writing on the backs of them, which shows through the cards, and mars the effect of the paintings. I have tried to scrape the ink off, but the scraping spoils the cards. Will some reader kindly direct me?—Amateur.

[51715.]—**Fluor Spar.**—I shall be glad if any reader will kindly give me any information respecting fluor spar. I have heard that it is used in the manufacture of glass and for fluxing purposes. Is this so, and what other scientific uses is it put to? Also what is the market value? I have met with a quantity of spar which forms the matrix of a vein; but as the crystals are so imperfectly formed, it is a question with me whether it is fluor or quartz spar. The colour is various, and it is moderately hard. Not having a knowledge of chemistry, I am unable to test it, and should therefore be glad to know a simple method proving what class it belongs to.—Carboniferous.

[51716.]—**Street Lighting.**—Would some reader kindly say whose are the best regulating burners to use on street gas-lamps, and what size burner should be used? Sugg's and Peeble's burners have been suggested. Also if a cheap and effectual reflector can be placed inside an ordinary lantern?—Luminous.

[51717.]—**Lantern Readings.**—I have a magic-lantern. I was thinking as it magnifies pictures, could it not be made to magnify printing? I have a small hand-bill that I should like to show on a small screen about 8ft. square. Can any one tell me how I could put the printing on the slides?—W. Jackson.

[51718.]—**Outdoor Officers of Customs.**—In entering this department of the Civil Service persons commence at £55 a year; the next division above this commences at £85 a year. I should be glad if some one can tell me whether they have to pass same examination to get to the £85 a year? If not, how do they get there? —R. O.

[51719.]—**Water-Motors.**—Can any of your readers give me an explanation of the following fact?—When we connect a hose to a water co.'s main we find that the water issues rather slowly; but let us squeeze the end of the hose and we find that the water issues with sufficient "force" to carry it up to a height of say 10ft. or 12ft., according to the size of the aperture. This fact seems inexplicable to me, because the pressure of the water is the same at every sq. in. in the hose. Will any one give me the rule by which I can find the number of gallons per min. that will pass through a hole of a certain area—the pressure per sq. in. being known? I think these queries will interest many other readers, now that the subject of water-motors are being brought so prominently before us.—Pressure Gauge.

[51720.]—**Electric Launch.**—I want to make an electric launch about 2ft. long. Would you tell me beam and depth, also the best way to set about the machinery? —A Learner.

[51721.]—**Sore Leg.**—Will any humane reader give information on the following case?—I have for some time been suffering from a bad leg, with at times excruciating pain in the calf and foot. There is a sore upon the same, about half-way betwixt the knee and ankle, about the size of a crown piece. The veins about appear knotted, as if from obstruction. I am 64 years of age; fleshy; health generally fair.—J. Dexter.

[51722.]—**Prevention of Rust in Firearms.**—Can any one inform me what lubricant is the best for preventing rust in the interior of gun and rifle barrels when laid by? I have found the much-vaunted vaseline to be a failure in this respect, as however well the barrels may be cleaned before its application, red rust is sure to make its appearance in a short time. Some substance would seem to be required which has a stronger affinity for oxygen than the iron itself. Mr. Allen would perhaps kindly give his opinion?—Rifle.

[51723.]—**Oxide of Copper Battery.**—How many cells are required to work a 5-candle power incandescent lamp? (2) For how many hours would the battery give a continuous current under such circumstances? (3) What is the cost of recharging each cell?—W. W. Sallett.

[51724.]—**Height of Barometer.**—Will some reader tell me what my barometer (aneroid) should stand at, suppose at London it stands 30, as published in the *Telegraph*? We are 238ft. above sea-level?—Norfolk.

[51725.]—**Printing Potato Sacks.**—I should be glad to learn how to print name and trade-marks on sacks, otherwise than by stencil plates? Any information would oblige.—Spuds.

[51726.]—**Boiler for Small Boat or Canoe.**—To "W. E. G."—Will this gentleman oblige me, a fellow reader, by giving the following information?—What size boiler shall I require to drive a vertical double-cylinder engine (slide-valves), 6in. stroke by 3in. bore? I am building a small boat 14ft. long by 2ft. 6in. wide, and am desirous of fixing in her engines as described, if I can get small enough boiler. I want her for speed on a smooth river. I propose fitting two propellers in her, one at bows the other at stern, driven direct by engine crankshaft. The propellers will be sunk at least 6in. under surface of water. I have large screw-cutting lathe and tools suitable for the job. Any information or hints will be thankfully received.—C. F. R.

[51727.]—**Alexandra Beehive.**—Having commenced bee-farming on a small scale this year, the letters which have appeared from time to time in the English Mechanic have interested me very much. As I make a point of doing all the work in connection with the bees myself—that is hive-making and sundries connected therewith—I am during the winter months going to make one or two hives, and as I have read about the perfect accommodation provided in the Alexandra hive, I thought of making one of that pattern, and shall be greatly obliged if some of our practical apiarians will give me such a description, with a drawing, if possible, as will enable me to construct one.—Rojam Semaj.

[51728.]—**Photography.**—Will Mr. Lancaster or any of our readers explain the cause of my failure in taking a picture? I have a ¼-plate camera with a good achromatic lens. My silver bath consists of nitrate of silver ½oz., distilled water 6oz., ¼ drachm of nitric acid, and ¼ grain of iodide of potassium. The plate is coated with Mawson's and Swan's positive iodised collodion, and I use an ordinary iron developer, and fix with a hypo. solution. After the picture is developed and fixed, it appears as if someone has smeared it with their hands, and afterwards fades away altogether. Would be much obliged if someone would take an interest in the matter. —E. F. Terrey.

[51729.]—**Electric Engine.**—Will some kind reader tell me if a motor with a Siemens' armature is self-starting? If so, could I make one with an armature 2 or 3in. long? If I can get one to move it will suit my purpose. If not self-starting, can you tell me any small sort, that is to work with small battery power? Also state quantity of wire.—W. G. Bennett.

[51730.]—**M.R. Locos.**—Wanted dimensions of 201, 200, 2061, 221A, 140, 887, 195, 200A, 603, 1123, 1093, and 1635, and stations of 40, 45, 75, 85, 150, 230, 250, 257, 259, 446, 538, 606, 680, 712, 786, 877, 878, 991, 1076, 1082, 1177, 1184, 1318, 1320, 1331, 1340, 1342, 1344, 1368, 1440, 1463, 1475, 1565, and 1567.—J. E. Spencer.

[51731.]—**Liability to Repair Road.**—To Mr. Wetherfield.—A. is the owner of two houses, the street in which they are situated being in very bad order. The local board repaired it. A. has to pay his share for repairing, but does not do so. Eighteen months after A. sells the houses to B. Six months after the purchase B. gets the bill for reparing sent to him. Can they compel him to pay it?—C. B.

[51732.]—**Crystoleum.**—Could some reader kindly oblige with the sort of varnish, or a recipe for one, for fixing prints to glass for crystoleum work? Also means of making them transparent? Ought they to be made transparent before or after fixing to the glass. A few hints on the crystoleum process will be very acceptable.—Novice.

[51733.]—**Retouching Negatives.**—I should feel much obliged to Mr. Lancaster or any other kind reader if he would give me some information on retouching negatives. I have Le Meritoire camera, &c., which I must say works admirably; but a friend or two have informed me my negatives require retouching, which I do not understand.—Amateur Photo.

[51734.]—**Scum Cock.**—What is the proper height to fix scum cock with regard to the working level of water? Which end ought it to be fixed—over the furnace, or the other? The boiler horizontal, external fired.—W. W. Evers.

[51735.]—**Boat.**—Will any reader assist me with full-size section drawings of a 12ft. by 3½ft. deep draught centre board sailing boat? I mean the shape of hull at say nine different points from stem to stern. I have drawings on 1½in. scale, but do not know how to take off full size.—Sir W. Waller.

[51736.]—**Mechanics.**—(a) Given length and time of (single) vibration of a simple pendulum. Find its amplitude. (b) Find the length of a pendulum which makes a single vibration in 1½ seconds ($g = 32$). Will any of "ours" kindly work out the above without the direct employment of textbook formulæ? We cannot follow the reasoning in Deschanel and Twisden. Has centrifugal force any further effect than a pull on the point of suspension?—Befogged Science Students.

[51737.]—**Engineering.**—Will any of your professional readers favour me, as one of the fathers interested in the practical question—"What shall we do with our sons?" with a little information as to the course usually adopted in training youths for the engineering profession? The alternative used to be—serve five or more years in the shops, or pay a premium, varying with the standing of the firm selected, in order to avoid some of the manual labour. I should like to know how far the rise of modern science colleges, which include a department for the practical teaching of this subject, has modified the old practice, and what terms are usually imposed on a youth who has passed the course at one of these institutions. Also, what is the system pursued at the works of our largest railway companies for recruiting their engineering staff?—X. Y. Z.

[51738.]—**Laundry Stove.**—Can any practical reader tell me if a stove with the flue at the back gives as much heat, and has as much draught, as a stove that has its flue at the top?—Laundryman.

[51739.]—**Waterproofing Sheets.**—Having observed the recipe for waterproofing sheets for covering waggons, I shall be glad if someone will tell me if it is a good one, and if it would do for putting over several sheets I have which are showing wear at the creases, and if it can be obtained already mixed: 95 gallons of linseed oil, 8lb. of litharge, 7lb. umber, boiled together 24 hours —coloured with 8lb. vegetable black.—Ramchullunder.

[51740.]—**Pills.**—Will some reader kindly inform me how the above are coated with silver and sugar.—Brown.

[51741.]—**Fixing Pipes to Harmonium.**—Will Mr. Fryer or some other reader kindly tell me how I can fix some organ pipes to a French harmonium (one of Alexandre Fils')? I propose making the pipes of paper. A few remarks as to tuning the pipes will oblige—Chemicus.

[51742.]—**Induction Coil.**—I am making a coil of following dimensions:—Core, 9in. long, ¾in. diam.; primary, two layers of No. 16; ebonite tube, 8in. long; central disc, 6in. diam. Having wound 1lb. of No. 36 (properly insulated) on one end of tube according to my original intention, I find 1¼in. distance left between outer layer of wire and edge of disc. I shall be glad to know (1) if the core and primary will allow more secondary; if so, (2) to what distance from edge of disc it will be safe to wind secondary; (3) the best battery for the coil when finished.—X. U. C.

[51743.]—**Staining.**—I have a large room that I wish to have stained a rather dark oak about 2ft. from the surbase to meet carpet, and want to know how I should do it, as I think I have seen painters use the stain with oil in it, which does not require varnishing afterwards.—Beta.

[51744.]—**Brazing Bicycle Head into Hollow Back.**—I have a hollow backed bicycle with a malleable cast iron head brazed for 2in. into the tube forming the hollow back, and then fastened with a pin passing through the tube and head. I wish to put a new head into the tube. Will some fellow-reader tell me how to braze it in after I have fitted it?—H. Jamieson.

[51745.]—**Voice Missing.**—I have suffered at intervals during the last two years from losing my voice. The first time was from over-exertion in blowing. I thought I had quite recovered about six months back, but a fortnight back I caught cold and my old complaint has returned. The most peculiar feature is that it goes or comes instantly; for instance, yesterday until about 11 o'clock I could only speak in a rusty whisper, when all at once my voice came and remained until evening, when I lost it again. What is the cause and cure.—R. S. Lladnar.

[51746.]—**Weak Ankles.**—I should take it as a favour if any of "ours" would inform me if an elastic stocking would make my ankles stronger, or I should be thankful for any other suggestions as to bathing them.—Brunswick.

[51747.]—**Coal Saver.**—Can any correspondent tell me if there has been an arrangement for saving coals like the following?—A number of flat pieces of sheet iron are placed obliquely behind the fire, and by some arrangement is supposed to send the heat into the room.—Brunswick.

[51748.]—**To Mr. Wetherfield.**—Will you kindly state, for the benefit of our readers in general, and for myself in particular, if under the judgment of the suit Dobbs v. Grand Junction Water Company consumers are justified in refusing to pay their water rate except on the scale of their parish assessment and not on the actual rent paid, as a deal of haziness exists in this matter, and the water collectors continue to demand the rates based on the higher scale. Thanks in anticipation.—Aqua.

[51749.]—**Motor.**—Will any reader kindly inform me if the pole pieces of a Siemens' armature would be at all affected by having steel flanges instead of brass? The armature of my motor has steel flanges, and I cannot make it work.—F. W. Leake.

[51750.]—**Washing Negatives.**—I should be obliged if some of our readers would kindly state what length of time they find it necessary to wash or soak their plates after development. I use well water, having no running supply of water. After developing I place the plate in water in a china dish, and allow to soak for ten or fifteen minutes, changing water five or six times. I then place plate in alum solution, and after that again wash plate same as before. I should like to know whether so much washing is necessary.—Rex.

[51751.]—**Pendulograph.**—How is this instrument constructed and used? I should feel greatly indebted for a full explanation, and a sketch would probably interest many readers besides the writer. The opticians are showing the most complicated and delicately traced designs made by its means, and some said to be produced by soundwaves. These productions are so beautiful that many would be interested in a practical exposition of the process.—J. L. M.

[51752.]—**Tricycle Making.**—I intend making a tricycle during the coming winter, and shall be glad if any reader who understands such things will tell me which type of machine would be most suitable for an amateur to make. I was thinking of one like Singer's Folding Challenge—that in which there is one large wheel behind the rider. This seems to me to offer the greatest advantages for an amateur mechanic, but I should like to have the opinions of others. Whatever machine I decide upon making, I hope Mr. Editor will find room for full detail drawings of it.—Grapho.

[51753.]—**Sugar, Agent in Decolourising.**—Can any correspondent tell me what is the acting agent in animal charcoal in decolourising sugar solutions?—Sugar Refiner.

[51754.]—**Agriculture.**—What is a fair average weight of mangolds, swedes, turnips, and carrots per acre? What is the average value when mature per acre and per ton?—Estate Agent.

[51755.]—**Legal—Medical Electrician.**—I beg to thank "Lex" for reply to query contained in "E.M." of the 24th ult. B., however, maintains that although the cures (for which the testimonials in question were given) were effected by A., the testimonials are the property of B. for the reason that A. was in B.'s employ at the time. A., however, contends that the skill by which the said testimonials were obtained being his (A.'s) absolutely, and having subsequently severed his connection with B., the testimonials are his (A.'s) property, B. having no possible right to set up such testimonials as evidence of his skill, seeing that he had nothing whatever to do with the treatment of the case for which the testimonials were given. The further reply of "Lex" on the rightful ownership of the testimonials will greatly oblige —Justice.

[51756.]—**Cartridges for Martini Henri.**—Will any reader of "ours" inform me with what powder the Martini Henri rifle cartridges are loaded, and what weight of powder (in drachms) used?—Thos. H. Hall.

[51757.]—**Bradford's Washing Machinery.**—Having been in the laundry line for some time, and heard a good deal of Bradford's machinery, I had the opportunity to buy a large Bradford's washing machine (second hand) the other day. Would some reader who has had practical experience in the above tell me how to go to work, as I have entirely failed to get the clothes clean, although I have kept close to the instructions furnished by the maker? I have given the clothes a good firsting for about ten minutes, and a seconding in nearly boiling water for about the same time, but still all the dirtiest parts have to be done by hand afterwards, which is a great loss and what I do not need to do after the other machines I have; but they are on a different principle and different maker.—One in a Fix.

[51758.]—**Fyfe-Main Arc Lamp.**—Would any reader kindly give a description of the Fyfe Main (standard) arc lamp? A sketch will oblige—Toluol.

[51759.]—**Escapement.**—To "R. E. B."—Will you kindly inform me why the verge escape-wheel teeth do not require oil? Also, why oil should not be applied to the impulse-pin of the lever escapement?—C. Bohn.

[51760.]—**Shoe Repairing.**—Will some practical reader of "ours" kindly answer the following?—I can make both rivet and pegged shoes, but cannot make sewn work. I have sewn two pairs of soles on, but my work rips soon after wearing. (1) What is the best hemp to use? (2) The best size awl and thread. (3) Am I to sew in the same line with former stitches or nearer the edge of welt? (4) Am I to hammer the leather before or after sewing it on? I have to fill up my time with repairing.—Crispin.

[51761.]—**Magneto Machine.**—I wish to make a magneto-electric machine for giving shocks. If one of "ours" can give me a rough sketch with proportions I should feel obliged.—T. F.

[51762.]—**Motor for Dynamo.**—I have a small dynamo that requires the power of about two men to drive properly. I had an idea that a water motor of about that power would drive it; but not having seen such a thing in motion, I thought perhaps it would not rotate quickly enough. I then thought if I made the pace quicker by using three cog-wheels I should lose a considerable amount of power. I have a cistern 50in. by 39in. by 32in., and it is 25ft. above the ground. Should I get pressure enough to work a motor properly? Would any of your readers advise me as to the best way of going to work in the matter?—Motor.

[51763.]—**Dividing Engine.**—Can any of your correspondents give me working particulars of the mechanism of the dividing engine? The part that bothers me is the

ASTRONOMICAL NOTES FOR OCTOBER, 1883.

The Sun.

Day of Month.	Souths.	At Greenwich Mean Noon.		
		Right Ascension.	Declination. South.	Sidereal Time.

The method of ascertaining the Sidereal Time at Mean Noon at any other Station will be found on p. 373 of Vol. XXXVI.

The Zodiacal light may now be seen in the East before sunrise.

Spots, faculæ, and other indications of Solar disturbances continue.

There will be an Eclipse of the Sun on October 30th; but, as it will be invisible in this country, it will suffice merely to mention it here.

The Moon

Is new at 5h. 54·3m. in the early morning of the 1st, and enters her First Quarter at 10h. 19·6m. a.m., on the 9th. She will be Full at 6h. 45·4m. a.m., on the 16th; enter her Last Quarter at 11h. 18·6m., on the night of the 22nd; and be New, for the second time this month, 3·2 minutes before midnight on the 30th. The tides may be expected to be rather high about the 16th.

Day of Month.	Moon's Age at Noon.	Souths.
	Days.	h. m.

21	20·3	4 23·9 a.m.
26	25·3	8 29·7 ,,
31	0·5	0 6·5 p.m.

The Moon will be in conjunction with Venus at 3 p.m. on the 1st; with Mercury 12 hours later; with Saturn at 9 a.m. on the 19th; with Jupiter at the same hour on the 23rd; with Mars at Noon on the 23rd; with Mercury again at 3 p.m. on the 29th; and lastly with Venus (also for the second time this month) at 11 o'clock on the night of the 31st.

There will be

A Partial Eclipse of the Moon

during the Early Morning of October 16th, but the Moon will set a little before the middle of it. We give the details adapted from the *Nautical Almanac.*

First Contact with the Penumbra, October 16th, 4h. 42·4m. a.m. First Contact with the Shadow, 5h. 59·1m. a.m. Middle of the Eclipse, 6h. 54·3m. a.m. Greenwich Mean Time.

Magnitude of the Eclipse (Moon's diameter = 1) 0·277.

The first contact with the shadow occurs at 132° from the Northernmost point of the Moon's limb towards the East.

The Moon will set at Greenwich at 6h. 25m. a.m.

Jupiter's Satellites.

Ec Eclipse; Oc Occultation; Tr Transit of Satellite; Sh Transit of Shadow; D Disappearance; R Reappearance; I Ingress; E Egress. The printing of a phenomenon in *italics* indicates that its visibility is rendered doubtful, either by the brightness of the twilight or by Jupiter's proximity to the horizon.

Mercury

Is an Evening Star at the beginning of October; but comes into Inferior Conjunction with the Sun at 1 a.m. on the 7th, after which he, of course, becomes a Morning Star. He pursues his westerly path (as regards the sun) up to noon on the 22nd, when he attains his Greatest Elongation West (18° 16′) and commences his return journey. His angular diameter, which is 10·2″ at the date of his Conjunction, decreases to 5·6″ by the end of October. He is by no means well placed for the observer.

Day of Month.	Right Ascension.	Declination South.	Souths.
	h. m.	° ′	h. m.
1	13 6·3	10 40·0	0 26·7 p.m.
6	12 52·3	8 15·9	11 49·3 a.m.
11	12 31·8	3 58·2	11 13·0 ,,
16	12 27·3	1 53·2	10 48·8 ,,
21	12 37·8	2 4·5	10 39·7 ,,
26	12 59·0	4 1·0	10 41·2 ,,
31	13 25·9	6 53·4	10 48·3 ,,

The pendulum-like path indicated by the above ephemeris lies wholly in Virgo. At 3 p.m. on the 4th, Mercury and Venus will be in conjunction. He will also be in conjunction with γ Virginis (1° 8′ South of that Star) at 7 p.m. on the 20th; but, of course, below our horizon.

Venus

Is an Evening Star—i.e., she souths after the sun; but as she is close to him, and both rises and sets practically in daylight during the whole of October, we defer for another month an ephemeris which would only occupy space needlessly.

Jupiter

Is a Morning Star; but as he rises soon after 11h. 30m. at the beginning of October, and about 10 p.m. at the end of it, we resume our ephemeris of him. His angular diameter continues steadily to increase, from 33·5″ on the 1st to 36·6 by the 31st. At 7 a.m. on the 27th he is in so-called Quadrature with the Sun.

Day of Month.	Right Ascension.	Declination North.	Souths.
	h. m.	° ′	h. m.
1	8 11·6	20 15·6	7 32·8 a.m.
6	8 14·4	20 7·4	7 16·0 ,,
11	8 17·1	19 59·8	6 59·0 ,,
16	8 19·4	19 52·8	6 41·6 ,,
21	8 21·5	19 46·6	6 24·1 ,,
26	8 23·4	19 41·3	6 6·3 ,,
31	8 24·9	19 36·9	5 48·1 ,,

This short path lies wholly in a blank part of the Constellation Cancer. The Conjunction of Jupiter with Mars (below our horizon) has been referred to under the head of the last-named planet.

Mars

Continues to be a morning star in so far as his Southing is concerned; but he rises about 10h. 50m. p.m. at the beginning of the month and soon after 10 at the end of it, so that he can be fairly well seen during the early morning hours. His angular diameter, albeit it increases from 7·6″ on October 1st to 9″ by the 31st, is still too small to render telescopic scrutiny of his disc of any avail; in fact, it will not be until quite the end of the year that anything in the shape of Areographical detail will be visible.

Day of Month.	Right Ascension.	Declination North.	Souths.
	h. m.	° ′	h. m.
1	7 39·5	22 19·8	7 0·8 a.m.
6	7 51·2	21 56·9	6 52·8 ,,
11	8 2·5	21 32·3	6 44·4 ,,
16	8 13·5	21 6·2	6 35·7 ,,
21	8 24·0	20 39·2	6 26·5 ,,
26	8 34·0	20 11·7	6 16·9 ,,
31	8 43·6	19 44·3	6 6·8 ,,

Hence it will be seen that Mars will travel from Gemini into Cancer. No star more conspicuous than δ Cancri lies in his path, but he will be found rather more than 2° north of this on the 28th. He will be in conjunction with Jupiter, and only 59′ north of that planet at 7 p.m. on the 19th.

Saturn

Is a Morning Star, too, reference being had to his Transit after Midnight; but he rises at 8 p.m. at the beginning of October, and about 6 in the evening at the end of it. Hence, he is visible during a considerable portion of the w hours of the night. His angular di

β Ceti	11	56	18·80	,,
Polaris	12	35	49·87	,,
ο Piscium	12	57	39·03	,,

The Method of finding the Greenwich Mean Time of Southing of either of the Stars in the above List on any other night in October, as also that of determining the Local Instant of its meridian passage at any other Station, will be found on p. 375 of Vol. XXXVI. It must be noted, however, that the rules there given are not rigidly accurate when applied to Polaris or any other tolerably close circumpolar star. They will probably, though, be found sufficiently so in practice.

RECENT RESEARCHES ON THE DISTANCE OF THE SUN.

THE Friday evening discourse during the meeting of the British Association was delivered by Prof. R. S. Ball, Astronomer Royal for Ireland. The following is the substance of his remarks:—

The problem which is to engage our attention this evening has been justly regarded as one of exceptional interest and importance. When we have learnt the distance of the sun we can measure the bulk of the sun and his diameter, we can measure the great planet Jupiter or the rings of Saturn, and the scale of the whole solar system becomes known to us. Again, when we attack the loftiest problem in practical astronomy, and seek to stretch a sounding line over the vast abyss which divides our system from the stars, it is the distance of the sun which we must use as our measuring rod. No pains should be spared to give to so fundamental a unit all the precision of which it is capable. Let us define accurately the magnitude to be measured. The actual distance from the earth to the sun is not constant. In these autumnal months the distance is rapidly decreasing. We are at this moment drawing nearer and nearer to the sun at the rate of a thousand miles an hour. Next Christmas we shall be about a million and a half miles closer to the sun than we are to-night. At the commencement of the new year we shall begin to recede. Next midsummer will find us as far from the sun as possible; then we shall draw in again, arrive next autumn where we are this autumn, and commence anew the cycle of changes I have indicated. Though these changes amount to millions of miles, yet they are at the utmost only a small fraction of the sun's distance. To superficial observation the sun always seems the same size, and hence there can be no great relative changes in its distance. There is no difficulty in understanding what is meant by the average distance of the sun. To express the idea with precision we may borrow the language of mathematics, and say that the distance from the earth to the sun consists of two parts—a large constant part and a small periodical part. The important problem, and the difficult problem, is the measurement of the large constant part. This is the question to be discussed in my lecture this evening. The early history of the subject is as easy to sketch as the latter part is difficult. For 14 centuries the doctrines of Ptolemy were adopted on the distance of the sun as on all other astronomical problems. The method of Ptolemy might have succeeded if the sun's distance could have been measured by thousands of miles instead of by tens of millions. As matters stand, Ptolemy's method was utterly inadequate to cope with the real difficulties of the question. It led him to a conclusion which we now know to have fallen far short of the truth. The real distance of the sun is twenty times as great as that which Ptolemy deduced from his observations. But Ptolemy's result was a great step in advance notwithstanding the tremendous error by which it was vitiated. The illustrious Huyghens, in the 17th century, hazarded a speculation, which seemed plausible at the time, and which we now know to have been reasonably correct. Huyghens compared the diameter of the planet Mars with the sun. He compared the diameter of Venus with the sun. The primitive instruments used were capable of making these measures with some accuracy. Huyghens knew that the earth was also a planet revolving outside the path of Venus and inside that of Mars. Was it not reasonable to assume that the bulk of the earth might be comparable with that of its fellow planets, and intermediate between the bulk of Venus and that of Mars? This assumption—and, of course, it was no more than an assumption—gave the means of guessing the distance of the sun, which was concluded to be about 100 million miles. When guesswork came to be replaced by measurement this estimate of the sun's distance was corrected. It was found to be too large. It was amended first to 95,000,000 miles then to 91,000,000 miles. This was subsequently found rather too small, and it is now generally thought that the sun's distance must be more than 92,000,000 miles but hardly so much as 93,000,000 miles. We have here a range of one million miles. The problem in its present condition can now be distinctly stated. We require to determine the sun's distance accurately to within 100,000 miles, or, to speak in round numbers, we desire to determine the distance of the sun accurately to one-thousandth part of its total amount. Is such a degree of accuracy obtainable? I believe that it is. I do not say that the problem has already been solved with this precision, but an approach has been made, and enough has been done to show that the accuracy I have indicated may be attained. But this margin is not really large when we reflect on the stupendous magnitude of the sun's distance. There are certain conditions which any method of measuring the sun's distance must fulfil. In the first place, it is obvious that we cannot measure the distance directly. We cannot take a tape and measure it as we would the length of a field. We are compelled to resort to indirect methods. In other words, instead of measuring the sun's distance directly, we measure something else, from which we derive the sun's distance by calculation. Whatever that something else may be there is one obvious condition which must be fulfilled. The method by which the calculation is to be made must be absolutely unimpeachable. The measurable quantity and the sun's distance must be connected together by inexorable logic. The theory may be difficult, but it must contain no trace of ambiguity or of indefiniteness. No question of mere judgment or of estimation should be admissible. The connection between the two results must be as tight as a demonstration in geometry. It has often been observed that at a meeting of the British Association the proceedings assume a certain tone in harmony with those branches of science with which our President for the time being has been specially identified. In recognition of this principle, which is both useful and appropriate, the first method which I shall allude to this evening is the exquisitely-beautiful mathematical calculation by which the distance of the sun can be elaborated from ordinary observations of the planets systematically conducted at our national observatories. This method was foreshadowed in the dynamical theory of Newton, and was wrought to perfection by Leverrier. It is based upon the great law of gravitation, and is intimately connected with the splendid discoveries in planetary perturbation which form so striking a chapter in modern astronomical discovery. There is a certain relation between two quantities, which, at first sight, seem quite independent. These quantities are the mass of the earth and the distance of the sun. It follows from the measurements of the intensity of gravitation on the earth's surface and from the known revolution of the earth around the sun that the sun's parallax has a determined ratio to the cube root of the mass of the earth. There is no uncertainty about this result, and the consequence is obvious. If we have the means of weighing the earth in comparison with the sun, then the distance of the sun can be immediately deduced. How, then, are we to place our great earth in the weighing scales? This is the problem which Leverrier has shown us how to solve, and he does so by invoking the aid of the planet Mars. If Mars in his revolution around the sun were solely swayed by the attraction of the sun, he would, in accordance with the well-known laws of planetary motion, follow for ever the same elliptic path. At the end of one century, or even of many centuries, the shape, the size, and the position of that ellipse would remain unaltered. Fortunately, for our present purpose, a disturbance in the orbit of Mars is produced by the earth. Although the mass of the earth is so much less than that of the sun, yet the earth is still large enough to exercise an appreciable attraction on Mars. The ellipse which Mars follows is not always the same. The shape of that ellipse and its position gradually change and the position in which the planet is found depends upon the mass of the earth. The place in which the planet is found can be determined by observation; the place which the planet would have had if the earth were absent can be found by calculation. The difference between the two is due to the mass of the earth, and when it has been measured the mass of the earth can be ascertained. The amount of displacement increases from one century to another; but, as the rate of growth is small, ancient observations are necessary to enable the measures to be made with accuracy. A remarkable occurrence, which took place more than two centuries ago, enables the place of Mars to be determined with great precision. On the 1st of October, 1672, three independent observers witnessed the occultation of the star ψ Aquarii by the planet Mars. The place of the star is known with accuracy, and hence we are provided with the means of accurately defining the point on the heavens occupied by Mars on the day in question. From this result, combined with the modern meridian observations, we learn that the displacement of Mars by the attraction of the earth has, in the lapse of two centuries, grown to about five minutes of arc (294 seconds). It has been maintained that this cannot be erroneous to the extent of more than a second, and hence it would follow that the earth's mass is determined to within one three-hundredth part of its amount. If no error were present this would give the sun's distance to about one nine-hundredth part, which approaches very closely to the limit we have indicated. Notwithstanding the intrinsic beauty of this method, and the very high auspices under which it has been introduced, it will, I think, hardly be found to fulfil all the needful conditions. We make no impeachment of the fidelity of the observations, and we feel no doubt that the displacement of the planet is mainly, if not entirely, due to the disturbing effect of the earth's attraction; but it seems quite impossible to be sure that some other cause, minute though it must be, may not also have contributed to the result. We cannot be absolutely sure that the theory is above suspicion. Interesting and beautiful though this method may be, we must rather regard it as a striking confirmation of the law of gravitation than as affording an accurate means of measuring the sun's distance. Several other methods have been employed by which we can place the earth in the weighing scales. Perhaps none of these methods is free from objection as a means of measuring the sun's distance. I must, however, mention one of them which has special claims on our attention of a very peculiar kind. This time we invoke the aid of that erratic member of our system known as Encke's comet. The comet completes a circuit around its ellipse in a period but little more than three years. It does not, however, move with uniform velocity. Around this remote part of its path the comet creeps languidly; but as it turns round and commences to approach the sun the pace gradually improves, and the comet itself swells up in dimensions and in splendour. Encke's comet, although so famous, is one of that numerous host of telescopic objects which seldom or never become bright enough to be visible to the unaided eye. It would, however, be unwise to assign much weight to the distance of the sun, which may be deduced from these researches. Notwithstanding the labours of many astronomers, the theory of the comet's motion is still not sufficiently perfect for this purpose. It cannot be pretended that this method would give the sun's distance to within a thousandth part, and accordingly this method must give place to those which have more claims to accuracy. One of the most celebrated methods of measuring the distance of the sun is derived from a combination of experiments on the velocity of light with astronomical measurements. This is a method of very great refinement and beauty, and although it does not satisfy all the necessary conditions, it is impossible in this lecture to avoid a brief reference to an investigation so remarkable. The principle of this method is easily enunciated. Though the velocity of light is stupendous, yet it has been possible to measure that velocity by experiment. The best determinations indicate that a ray of light would flash over a distance equal to seven times the circumference of the earth in a single second of time (300,400 kilomètres). A ray of light would travel from Southport to London in about the thousandth part of a second. The dimensions of the solar system are, however, so considerable that even a sunbeam requires an appreciable interval of time to span the abyss which separates the earth from the sun. Eight minutes is approximately the duration of the journey. In fact, if the sun were to be suddenly blotted out it would still be seen shining brilliantly for eight minutes after it had really disappeared. Viewed as a means of measuring the sun's distance, it would be necessary to determine this interval accurately to half a second. Does astronomy hold out any prospect of our being able to measure this interval with such nicety? This question is intimately connected with two of the most brilliant discoveries in the annals of astronomy. Although they are well known to every one who has paid any attention to this science, yet I must refer to them briefly to examine how far they admit of the needful precision. Everyone who has had the opportunity of using an astronomical telescope is familiar with the exquisite system of four moons which grace the great planet Jupiter. These little bodies led 200 years ago to the discovery of the velocity of light. In their frequent revolutions the little satellites plunge occasionally into the vast and dense shadow thrown by the mighty planet. The sun's light which had previously rendered the little satellite a glittering point of light is then cut off, the satellite becomes invisible, and we say that it is eclipsed. This is a most pleasing phenomenon to witness, and as the satellites revolve so rapidly, the eclipses occur with great frequency. From the discussion of previous observations of the satellites we have become aware of the nature of their movements, so that the advent of eclipses can be predicted, and even the time of their occurrence. But the time at which the eclipse takes place is not identical with the moment at which we see the eclipse. If we could calculate the moment when the eclipse really took place, and if we could observe the moment at which the eclipse is seen, the difference between the two gives the time which the light occupies on the journey. At both extremities of the process there are characteristic sources of uncertainty. The occurrence of the eclipse is not an instantaneous phenomenon. The little satellite is large enough to require an appreciable time in crossing the boundary which defines the shadow, so that the observation of an eclipse is not sufficiently precise to form the basis of an important and accurate measurement. Still greater difficulties accompany the attempt to define the true moment of the occurrence of the eclipse as it would be seen by an observer in the vicinity of the satellite. For this we would require a far more perfect theory of the movements of Jupiter's satellites than is at present attainable. This method of finding the sun's distance holds out no prospect of a result accurate to the one-thousandth part of its amount, and therefore we may discard it. But there is yet another method by which the experimental determination of the velocity of light can be so combined with purely astronomical measurements as to yield the sun's distance as a result. Time will not permit that I should enter into this subject, which is identified with one of the most glorious discoveries of astronomy—namely, the aberration of light. But here I would only remark that this method does not fulfil the condition of geometrical necessity. It has not even the somewhat inferior attribute of dynamical necessity. The physical conceptions introduced may to some degree be open to question. Is it certain that the velocity of light [illegible] is the same as the velocity of light through [illegible]? Is it certain that the motion of the whole solar system can be suitably allowed for and eliminated? The time has not yet arrived when these latter questions can be fully answered. The most accurate method of measuring the distance from the earth to the sun is without doubt that which is afforded by the transit of Venus. This has engrossed more attention than all the other methods together. On four occasions the attempt has been made to find the sun's distance by its aid; the last of these occurred only last December, and another opportunity will not occur until June in 2004. It was formerly supposed, and it is, no doubt, still maintained by many, that the transit of Venus is *par excellence* the method, but the growth of practical astronomy has tended to question the supremacy of the transit of Venus. An attack has been made in two distinct directions. It has on the one hand been shown that the transit of Venus is incapable of the accuracy that was at one time claimed for it. On the other hand, the new method by the aid of the minor planets has arisen. I do not, however, believe that the transit of Venus can be expected to give the distance accurately to one-thousandth part. It is impossible to define the contacts with the precision that would be required. It was on the first night of the present century, a date very easy to remember, that the first of the minor planets was discovered; a few others were quickly added, and 40 years later the career of discovery was reopened. Fresh planets were added by units, by tens, and by scores, until at the present moment we recognise about 240 of these objects revolving around the sun in the gap between Mars and Jupiter. The sun, which controls the mighty planets of our system, does not disdain to guide with equal care the tiny globes which form the minor planets. Each revolves in an elliptic orbit, and at certain times some of them approach near enough to the earth to have their distances measured. The observations can be made with very great precision; they can be multiplied to any extent that may be desired. They can be discussed with geometrical accuracy, so that from them one result and only one can be deduced. In speaking of these planets as small objects, I must be understood to use the word in a comparative sense. They are small as planets, but perhaps the area of an average one might be comparable with that of a good-sized English county. The discoveries of minor planets have added enormously to the labours of those astronomers who compute the movements of the solar system. The task of predicting the places of the minor planets has been for many years most ably accomplished in the Berlin "Ephemeris." The editor must be sometimes alarmed at the daily extension of his list. Many of these bodies are of but little interest. Perhaps it would be no great harm to allow a good many of them to get lost again, and be no more followed by telescopes or computers. Some of these little bodies have, however, a great astronomical future. They seem destined to tell us more faithfully than Venus or than Mars what is really the distance from the earth to the sun. The very small ones will not answer; they can only be seen in very powerful telescopes, and they do not admit of being measured with the necessary accuracy. It is also obvious that the planets to be chosen must be as near to the earth as possible. They should have orbits possessing a high degree of eccentricity, so that when in perihelion and in opposition simultaneously the approach may be made as close as possible. Under favourable circumstances a minor planet will approach the earth to a distance but little more than three-quarters of the distance of the sun. These various conditions limit the number of minor planets available for this purpose to about a dozen, of which one or two will usually be suitable each year. About two years ago Mr. Gill invited astronomers in the northern hemisphere to co-operate with him in the southern in an attempt to apply this method to Victoria and to Sappho. It became my duty to co-operate in this scheme, so far as my opportunities went. As the planet pursues its course through the sky, and as the sky is everywhere studded over with countless myriads of minute stars, it is evident that the planet itself so like a star will always have some stars in its immediate neighbourhood. As the movements of the planet are well known, it is possible to foretell where it will be on each night that it is to be observed. The scheme was completely drawn up many months before the observations were to commence. Each observer who participated in the work was thus advised beforehand of the stars which were to be employed each night. Viewed from any part of the earth, from the Cape of Good Hope or from Great Britain, the positions of the stars are absolutely unchanged. Their distance is so stupendous that a change of place on the earth displaces them to no appreciable extent. But the case is different with Victoria. It is hardly one-millionth part of the distance of the stars, and thus the displacement of the planet when viewed from the Cape and when viewed from Europe is measurable. The measurements are made from a comparison star with a micrometer or a heliometer. The star is one beautifully-defined point, the planet is another, and the difference of declination between the two can be measured with a high degree of accuracy. Two comparison stars symmetrically placed with regard to the planet are usually employed, as a number of sources of error can be thus eliminated. The displacement of the planet is to be elicited by comparison between the observations in the northern hemisphere with those in the southern hemisphere. The observations must be made as nearly as possible at the same time, due allowance being made for the motion of the planet in the interval. Although every precaution is taken, yet the fact remains that we are obliged to compare the measures made by observers in the northern hemisphere with those made by different observers, and, of course, different instruments in the southern hemisphere. In this respect we are, no doubt, at no greater disadvantage than in the transit of Venus; yet is is possible to obviate even this difficulty, and thus to give the minor planet method a great advantage over its rival. The difficulty would be overcome if we could conceive that an observer and his observatory, after making a set of observations on a fine night in one hemisphere, were to be transferred, instruments and all, to the other hemisphere, and there to repeat the observations. This problem can be solved without any miraculous agency, and in it we have undoubtedly the most perfect mode of measuring the sun's distance with which we are acquainted. This method has already been carried out with success by Mr. Gill in the case of Juno, but there are other planets more favourably situated, and the work can be done for a mere fraction of the expense of the much more cumbrous transit of Venus. Take, for instance, one of the little planets which sometimes approach to within 70,000,000 miles from the earth. When the opposition is drawing near, a skilled observer is to be placed on some suitable station near the equator. The instrument he is to use should be the heliometer. It can be used to measure stars at a greater range than is attainable with the filar micrometer. The measurements are to be made in the evening as soon as the planet has risen high enough to enable it to be seen distinctly. The observer and the observatory are then to be transferred to the other side of the earth. How is this to be done? Say, rather, how you could prevent it being done? Is not the earth rotating around its axis, so that in the course of a few hours the observatory on the equator is carried bodily round for thousands of miles? Before the morning dawns the observations are to be repeated. The planet is found to have changed its place very considerably with regard to the stars. This is partly due to its own motion, but it is also largely due to the parallactic displacement arising from the rotation of the earth, which may amount to as much as 20 seconds. The measures on a single night with the heliometer should not have a mean error greater than one-fifth of a second, and we might reasonably expect that observations could be secured on about 25 nights during the opposition. Four such groups would give the sun's distance to one-thousandth part. The chief difficulty of the process arises from the motion of the planet during the interval which divides the evening from the morning observations. This, it must be admitted, is a drawback to the method. It can, however, be avoided by diligent and and repeated measurements of the place of the planet with respect to the stars among which it passes. Let us hope that long before another transit of Venus shall come round the problem will have been satisfactorily solved by the minor planets. It will surely be expected that I shall not close this lecture without an attempt to say what the distance of the sun is so far as modern research has gone. Reviewing all the different methods, the most probable value seems to be 92,700,000 miles. It does not seem likely that this can be erroneous to the extent of 300,000 miles.

GALVANI AND ANIMAL ELECTRICITY.

THE Monday evening discourse during the meeting of the British Association was delivered by Prof. McKendrick, F.R.S., who said:—

In these days, when electricity is commanding universal attention as a great force capable of being made subservient to humanity, it may be appropriate to consider some of the phenomena of electricity produced by living tissues and by living organs, or what is called animal electricity. Most of the modern developments of electrical science trace their origin to the physiological experiments of Galvani, the Professor of Anatomy at Bologna in 1786. In the critical inquiry made by Volta into the question started by Galvani, he was led to the invention of the Voltaic pile, which not only for a time threw into neglect the question of animal electricity, but also was the starting point of the electrical science of the present day. In 1820 Oersted made the discovery of electro-magnetism. This led to the invention of the astatic needle (Ampère), and of the multiplier or galvanometer (Schweigger); and in 1827 Nobili constructed a galvanometer of great sensibility, by which he could reinvestigate the question of whether or not currents of electricity could be obtained from animal tissues. He found that such currents did exist, and he supposed they were due to thermo-electric action. About 10 years thereafter (1837) Matteucci, of Pisa, again investigated the matter, and found that currents could be obtained from animal structures, even where all suspicion of thermo-electric or chemical action was removed. He also discovered that the interior of muscles was negative to their surface, and that it was possible to make a kind of battery of the thighs of newly-killed frogs, which could produce chemical effects similar to those caused by Voltaic elements. Then came the labours of Du Bois Reymond, the present Professor of Physiology in the University of Berlin, which will always mark the commencement of an epoch in the history of animal electricity. Recognising that the detection of the feeble currents from animal structures depended on the delicacy and accuracy of the apparatus employed, he made many improvements in the construction of galvanometers, and in the arrangements for leading off the currents from living textures into the galvanometer. Such galvanometers must be exquisitely sensitive, and it is evident that just in proportion as they are so, so will be the difficulty of making an arrangement which will lead off any current that may exist, say in living muscles, without causing a current itself. If we apply to a bit of muscle the ends of the copper wires coming from a delicate galvanometer we either get no effect or an effect due to the action of the muscle substance, or the fluid covering it, on the copper wire. We must have some arrangement, which, while touching the muscle, will not cause any chemical change in it, and at the same time will draw off into the galvanometer circuit any current that may come from the muscle itself. That is, the electrodes of the galvanometer must be non-polarisable, even when touching muscle. Du Bois Reymond found that little troughs of zinc, filled with a saturated solution of sulphate of zinc, fulfilled these requirements. Into these are placed bits of blotting-paper, also wet with sulphate of zinc solution, and on the bits of blotting-paper are placed morsels of clay moistened with saliva. When the bits of clay are put into contact so as to make a circuit, no current passes through the galvanometer. If we now take a muscle from the back of the leg of a frog, cut it across, and place it on the clay pads so that the section of the muscle touches one pad and the surface of the muscle the other, a current of electricity passes through the galvanometer, as shown by the swing of the needle. This was shown by the lecturer, a beam from a limelight being reflected on a screen by a mirror attached to the needles of the galvanometer. It was then shown that an uninjured frog's muscle gives no current; that no current can be got from two uninjured surfaces nor from two transverse sections; but only, speaking generally, when one clay pad touches a section and when the other touches a surface. This may be called muscle-current. A similar current, though much weaker, can be obtained from living nerve. It was also shown that when a muscle is caused to contract, as it does naturally, the so-called muscle-current is diminished; at all events, suppose the current from a muscle brings the needle of the galvanometer to a certain point, if the muscle then be caused to contract, the needle will swing back to nearly its zero point. This reverse—the so-called negative variation—indicates that an electrical change in the muscle happens when it contracts. But by refined methods of experiment it has been shown that this change really occurs before the muscle contracts—that is, the change in the electrical state of the muscle is an expression of the chemical changes occurring in it, which are antecedent to the muscular movement. Much discussion has taken place as to what these currents really mean; but the majority of physiologists agree with Hermann, of Zurich, in thinking that the current obtained on cutting or injuring the muscle or nerve is really due to the dying of the muscle or nerve substance at the point of section, and that the so-called "negative variation" is the current indicating functional activity. That is, living substance dies at the plane of section, and in dying it acquires a lower potential than the living matter, thus giving rise to a current. Again suppose a living muscle giving no current, on stimulating it, by irritating its nerve, so as to cause the muscle to contract, a lower potential is produced at the points in the muscle where the nerve fibres end, and there is thus a negative variation. Further, it has been shown that this negative variation passes like a wave through the muscle substance, and that the wave has disappeared before the muscle contracts. If, then, electrical changes occur during the activity of muscle and nerve, it is natural that physiologists might expect to detect changes in the beating heart. This is the case. It was shown, by projecting its image on a screen that the uninjured frog's heart, isolated from the body, still lives, and while beating, gave with each beat an electrical variation, as shown by the swing of the galvanometer needle. The uninjured heart gives no current, but when slightly injured there is a variation in its electrical state with each beat. Then the lecturer showed that light causes an electrical change in the eye. Placing the eye of a frog in the galvanometer cushions, it was shown that there was a current passing from the cornea to the back of the eye. In the dark little or no change could be seen except what might be due to the drying of the living structures forming the eye; on allowing light to fall on the eye, there was at once an increase in the current. This continued for a time, then began to fall off, and, on light being removed, there was another increase, and then a sudden and rapid fall off. This action, first shown by Prof. Holmgren, Prof. Dewar, and the lecturer, showed a specific influence of light on the retina. It could not be called a negative variation. It indicated chemical changes occurring in the retina. Lastly, the lecturer showed the production of currents from the living man. Placing the hands in two vulcanite troughs, communicating by platinum plates with the galvanometer and filled with a weak solution of salt, he showed that on contracting one arm, a deflection of the galvanometer needle was produced. When both arms were quiet there was no current: on contracting one arm a current was at once produced. This current, the lecturer was inclined to think, was due to action of the fluid on the skin, and not to currents from the muscles, and that the differences were due to differences of contact. In summing up, after a few remarks regarding electric fishes, the lecturer said that all of these electrical changes were really expressions of the vital changes occurring in living tissues under the action of stimuli. It was no part of the functions of nerves, muscles, or of the retina of the eye to produce currents under the action of their relative stimuli; but such currents indicated chemical changes in the organs or tissues. For example, the contraction of a muscle is a movement following or consequent upon many chemical changes, among the results of which were the production of heat and differences of electrical potential. Thus there was no special production of electricity, except in the case of electrical fishes and possibly of some other animals. In most animals, including man, the production of currents was an incidental phenomenon, indicating chemical operations and nothing more. Besides, the currents so produced were feeble and evanescent, and bore no relation to the general well-being. Consequently all attempts to influence the living body by magnets had no rational basis. Prof. McKendrick said he had tested this question by powerful electro-magnets, and had not been able to detect that they had the slightest influence on any vital phenomena. It need hardly be added that the so-called phenomena of animal magnetism are of an entirely different kind from those discussed. These are of a subjective character, dependent on peculiar states of the nervous system, having nothing whatever to do with electricity or magnetism; but still in a sense they are phenomena as real as those of physical science. Their subjective character, however, renders them specially difficult of investigation, and consequently they are more liable to fall into the hands of the charlatan. One safeguard against this is the recognition of what the electrical phenomena of the living body really mean, and one purpose of this lecture will be served if it shows that to detect and account for these phenomena requires the most refined methods of the physicist and of the physiologist, and that they give us only a glimpse into the intricate changes occurring in living tissue.

The New Bankruptcy Law.—Mr. F. Wetherfield, of 2, Gresham-buildings, Guildhall, has issued a handy and comprehensive guide to the new Law of Bankruptcy, which will be of considerable use to all traders. Speaking broadly of the new Act, Mr. Wetherfield thinks it will be more expensive in its actual working than any former statute. But if it really saves creditors being defrauded by their debtors and prevents trustees from making away with the funds, this costliness will repay itself. There is every reason to believe that debtors, at all events, will be more sharply looked after than they have ever been before, and that a tight hand will be held upon their estates, while creditors, even, and certainly their trustees, will be under the same sort of strict supervision. Mr. John Rae, LL.D., F.S.A., has also issued a similar treatise, which is published by Messrs. Marlborough and Co., of 51, Old Bailey. Mr. Rae says:—"Altogether the Act exhibits boldness, comprehensiveness, and strength. Wrought by an infinity of labour, guided throughout by an inflexible purpose of reform, experience will test its efficiency and grandeur: time must reveal and record the verdict upon its wisdom and consolidation."

M. Antony Guyard has devised a photometer of considerable delicacy, dependent on the decomposition of iodide of nitrogen placed in aqueous ammonia, which is proportional to the intensity of light. The volume of nitrogen evolved in a given time is a measure of the amount of luminous radiation.

BRITISH ASSOCIATION.

THE ADDRESS IN MATHEMATICS AND PHYSICS.

THE address in Section A was delivered by Prof. Olaus Henrici, F.R.S., the president, and was devoted mainly to a discourse on that branch of mathematics which has held most attraction for Prof. Henrici--viz., pure geometry as apart from algebra. The following is an abstract of the address:—Pure geometry seems to me to be of the greatest educational value, and almost indispensable in many applications; but it has scarcely ever been introduced at Cambridge, the centre of mathematics and mathematical education in England. The number of geometrical methods now in use is astonishingly great. These differ, on the one hand, according to the nature of the result aimed at, but, on the other, according to the amount of algebra employed, and to the relation in which this algebra stands to the pure "*Anschauung*" (intuition by inspection). It is the inspection of figures which is of the greatest importance in geometry. It is hereby of little consequence whether the figures are seen by the physical eye or only mentally; because the conception of that space in which we perceive everything and without which we can perceive nothing, which therefore is, according to Kant, a form of our *Anschauung*, is built up in our mind through many generations in conformity with sensual impressions.

In some of the methods just referred to no algebra is used at all, whilst others may be distinguished according to the nature of the algebra used, whether equations containing one, two, three, or more variables are employed. In such a division, Von Staudt's system, without a vestige of algebra, would occupy the one end, and the purely algebraical theory of invariants with geometrical interpretation the other. There is, however, not only a difference in the amount of algebra used, but, if possible, a greater one in the manner in which the symbols are interpreted. And it is here that algebra has apparently the greater power. One algebraical theorem, by being read in different ways, by giving ever different meanings to the symbols, reveals a variety of geometrical and other theorems. We have in it the crystallised form, the very essence of the mathematical truth, but in the most abstract form conceivable. Now this most abstract form is the highest and the most perfect which mathematical truth as such can assume, and which it must assume before a theory is really complete in the eyes of a pure mathematician. It is only in this shape that it is ready to be turned to account in any direction where it may be needed.

In thus placing algebra on the highest pinnacle, the reasons will be apparent which will make many mathematicians, not to mention others, prefer the truths it reveals cast in a mould which connects them with concrete things rather than with abstract notions. In fact, to be thoroughly at home in the highest theories of pure algebra requires some of the genius of men like Cayley and Sylvester who have founded, and to a great extent built up, modern algebra. But even they constantly make use of geometry to assist them in their investigations, and no one could have expressed this more strongly than Prof. Sylvester himself in his brilliant address delivered from this chair at the Exeter meeting of our Association.

If this is so, surely every progress in the spread of the knowledge of pure geometry should be welcomed and encouraged; but in England pure geometry is almost unknown excepting in the elements as contained in Euclid and in the old-fashioned geometrical conics. The modern methods of synthetic projective geometry as developed on the Continent have never become generally known here.

The best analytical methods of the Continent were introduced into England, rapidly assimilated and made the foundation of new theories, so that the mathematical activity in this country is now at least as great as it ever has been anywhere.

But whilst analysis, algebra, and with it analytical geometry, made rapid progress, pure geometry was not equally fortunate. Here the hold which Euclid had long obtained, strengthened, no doubt, by Newton's example, prevented any change in the methods of teaching.

Most of all, perhaps, solid geometry has suffered, because Euclid's treatment of it is scanty, and it seems almost incredible that a great part of it—the mensuration of areas of simple curved surfaces and of volumes of simple solids—is not included in ordinary school teaching. The subject is, possibly, mentioned in arithmetic, where, under the name of mensuration, a number of rules are given. But the justification of these rules is not supplied, except to the student who reaches the application of the integral calculus; and what is almost worse is that the general relations of points, lines, and planes, in space, is scarcely touched upon, instead of being fully impressed on the student's mind.

Pure geometry has become a most important instrument for research, rivalling in power the more or less algebraical methods, and surpassing them

[illegible]

THE ADDRESS IN CHEMISTRY.

The address in Section B was delivered by the president, Prof. J. H. Gladstone, F.R.S., who, in the course of his remarks, said:—Though theoretical and practical chemistry are now intertwined, with greatest advantage to each, they appear to have been far apart in their origin. Practical chemistry arose from the arts of life, the knowledge empirically and laboriously acquired by the miner and metallurgist, the potter and the glassworker, the cook and the perfumer. Theoretical chemistry derived its origin from cosmogony. In the childhood of the human race the question was eagerly asked, "By what process were all things made?" and some of the answers given started the doctrine of elements. The earliest documentary evidence of this is probably contained in the Shu King, the most venerated of the Chinese classics for its antiquity. It is an historical work, and comprises a fragment of still more venerable age, called "The [illegible], with its Nine Divisions," which purports to have been given by Heaven to the [illegible] to teach him his royal duty and "the proper virtues of the various relations."

Dr. Gladstone proceeded to give an interesting resumé of the history of elements as understood by the Chinese, the Indian races, the Greeks, and the Arabs, and having brought it down to modern times he proceeded:—

In this ever-growing list of elements not one has been resolved into simpler bodies for three-quarters of a century; and we, who are removed by two or three generations from the great builders of our science, are tempted to look upon these bodies as though they were really simple forms of matter, and not only unresolved, but unresolvable. The notation we employ favours this view and stamps it upon our minds. Is it, however, a fact that these reputed elements are really simple bodies, or, indeed, are they widely different in the nature of their constitution from those bodies which we know to be chemical compounds? Thus, to take a particular instance, are fluorine, chlorine, bromine, and iodine essentially distinct in their nature from the compound halogens, cyanogen, sulphocyanogen, [illegible], &c.? Are the metals lithium, sodium, and potassium essentially distinct from such alkaline bases as ammonium, ethylamine, di-ethylamine, &c.? No philosophical chemist would probably venture to answer this question categorically with either "yes" or "no."

It was at first hoped that the spectroscope might throw much light upon the nature of elements, and might reveal a common constituent in two or more of them. Thus, for instance, it was conceivable that the spectrum line of bromine or iodine vapour might consist of the rays given by chlorine *plus* some others. All expectations of this have hitherto been disappointed; yet, on the other hand, it must not be supposed that such a result disproves the compound nature of elements, for as investigation proceeds it becomes more and more clear that the spectrum of a compound is not made up of the spectra of its component parts. Again the multiplicity of rays given out by some elements, when heated in a gaseous condition, such as iron, has been supposed to indicate a more complex constitution than in the case of those metals, such as magnesium, which give a more simple spectrum. Yet it is perfectly conceivable that this may be due to a complexity of arrangement of atoms all of the same kind. Again, we have changes of a spectrum at different temperatures: new rays appear, others disappear; or even there occurs the very remarkable change from a fluted spectrum to one of sharp lines at irregular intervals, or to certain recurring groups of lines. This, in all probability, does arise from some redistribution, but it may be a redistribution in a molecular grouping of atoms of the same kind, and not a dissociation or rearrangement of dissimilar atoms.

A stronger argument has been derived from the revelations of the spectroscope in regard to the luminous atmospheres of the sun. There we can watch the effect of heat enormously transcending that of our hottest furnaces, and of movements compared with which our hurricanes and whirlwinds are the gentlest of zephyrs.

At the meeting of this Association at Ipswich, in 1851, M. Dumas showed that in several cases analogous elements form groups of three, the middle one of which has an atomic weight intermediate between those of the first and third, and that many of its physical and chemical properties are intermediate also. During the discussion upon his paper, and subsequently, attention was drawn to the fact that this is not confined to groups of three, but that there exist many series of analogous elements having atomic weights which differ by certain increments, and that these increments are in most cases multiples of 8. Thus we have lithium, 7; sodium, 23, *i.e.* 7 + 16; potassium, 39, *i.e.* 7 + (16 × 2); and the more recently discovered rubidium, 85, *i.e.* 7 + (16 × 5) nearly; and cæsium, 133, *i.e.* 7 + (16 × 8) nearly. This is closely analogous to what we find in organic chemistry, where there are series of analogous bodies playing the part of metals, such as hydrogen, methyl, ethyl, &c., differing by an increment which has the atomic weight 14, and which we know to be CH_2. Again, there are elements with atomic weights nearly the same or nearly multiples of one another, instances of which are to be found in the great platinum group and the great cerium group. This suggests the analogy of isomeric and polymeric bodies. There is also this remarkable circumstance; the various members of such a group as either of those just mentioned are found together at certain spots on the surface of the globe, and scarcely anywhere else.

The specific refraction has been determined for a large majority of the elements, and is a very fundamental property, which belongs to them apparently in all their combinations, so long at least as the atomicity is unchanged. If the figures representing this property be inserted into Mendelejeff's table, we find that in the vertical columns the figures almost invariably decrease as the atomic weights increase. If, however, we look along the horizontal columns, or better still if we plot the figures in the table by which Lothair Meyer has shown graphically that the molecular volume is a periodic function of the atomic weights, we shall see that they arrange themselves in a series of curves similar to but not at all coincident with his. The observations are not so complete or accurate as those of the molecular volumes, but they seem sufficient to establish the fact, while the points of the curves would appear to be, not the alkaline metals, as in Meyer's diagram, but hydrogen, phosphorus and sulphur, titanium and vanadium, selenium, antimony. Now, if we were to insert the specific refractions of cyanogen, ammonium, and methyl into this table, we should again show that it was an intrusion of strangers not in harmony with the family of elements.

But there is another argument to be derived from the action of light. The refraction equivalent of a compound body is the sum of the refraction equivalents of its compounds; and, if there is anything known for certain in the whole subject, it is that the refraction equivalent of an organic compound advances by the same quantity (7·6) for every increment of CH_2. If, therefore, the increment between the different members of a group of analogous elements, such as the alkaline metals, be of the same character, we may expect to find that there is a regular increase of the refraction equivalent for each addition of 16. But this is utterly at variance with fact; thus, in the instance above quoted, the refraction equivalent of lithium being 3·8, that of sodium is 4·8, of potassium 8·1, of rubidium 14·0, and of cæsium about 13·7.

The general tendency of these arguments is evidently to show that the elementary radicals are essentially different from the compound radicals, though their chemical functions are similar.

There remains still the hypothesis that there is a "primordial element," from which the others are derived by transmutation. With the sages of Asia it was the "blue ether," with Thales water, with Dr. Prout hydrogen. The earlier views have passed away, and the claims of hydrogen are being fought out on the battle-field of atomic weights and their rigorous determination.

There does not appear to be any argument which is fatal to the idea that two or more of our supposed elements may differ from one another rather in form than in substance, or even that the whole seventy are only modifications of a prime element; but chemical analogies seem wanting. The closest analogy would be if we could prepare two allotropic conditions of some body such as phosphorus or cyanogen, which should carry their allotropism into all their respective compounds, no compound of the one form being capable of change into a compound of the other. Our present knowledge of allotropism and of variations in atomicity, affords little, if any, promise of this.

The remarkable relations between the atomic weights of the elements, and many peculiarities of their grouping, force upon us the conviction that they are not separate bodies created without reference to one another, but that they have been fashioned or built up from one another according to some general plan. This plan we may hope gradually to understand better, but if we are ever to transform one of these supposed elements into another, or to split up one of them into two or three dissimilar forms of matter, it will probably be by the application of some method of analysis hitherto unknown.

THE ADDRESS IN GEOLOGY.

The address in Section C was delivered by Prof. W. C. Williamson, F.R.S., the president, who gave an interesting and almost elaborate sketch of the present state of our knowledge of the vegetation of the Carboniferous Age. After pointing out that while German and English palæontologists are in substantial agreement, French savants take different views of what is to be learned from the fossil plants, Prof. Williamson proceeded to say:—The common state in which our fossil plants are preserved presents a source of error that is positive as well as negative. Most of those from our coal measures consist of inorganic shale, sandstone, or ironstone, invested by a very thin layer of structureless coal. The surface of the inorganic substance is moulded into some special form dependent upon structural peculiarities of the living plants, which structures were sometimes external, sometimes internal, and sometimes intermediate ones. Upon this inorganic cast we find the thin film of structureless coal, which, though of organic origin, is practically as inorganic as the clay or sandstone which it invests; but its surface displays specific sculpturings which are apt to be regarded as always representing the outermost surface of the plant when living, whereas this is not always the case. That the coaly film is a relic of the carbonaceous substance of the living plant is unquestionable; but the thinnest of these films are often the sole remaining representatives of structures that must originally have been many inches, and in some instances even many feet, in thickness. In such cases most of the organic material has been dissipitated, and what little remains has often been consolidated in such a way that it is merely moulded upon the sculptured inorganic substance which it covers, and hence affords no information respecting the exterior of the fossil when a living organism. It is, in my opinion, from specimens like these that the smooth bark of the Calamite has been credited with a fluted surface, and the Trigonocarpons with a merely triangular exterior and a misleading name, as it long caused the inorganic casts known as Sternbergiæ to be deemed a strange form of plant that had no representative amongst living types. In other cases the outermost surface of the bark is brought into close contact with the surface of the vascular cylinder. I have a Stigmaria in which the bases of the rootless appear to be planted directly upon that cylinder, the whole of the thick intermediate bark having disappeared. In other examples that vascular zone has also gone. Thus the innermost and outermost surfaces of a cylinder, originally many inches apart, are, through the disappearance of the intermediate structures, brought into close approximation. In such cases, leaves and other external appendages appear to spring directly from what is merely an inorganic cast of the interior of the pith. I believe that many of our Calamites are in this condition. Such examples have suggested the erroneous idea that the characteristic longitudinal flutings belong to the exterior of the bark.

Entering upon a more detailed review of our knowledge of the Carboniferous plants, and commencing at the bottom of the scale, we come to the lowly group of the Fungi, which are unquestionably represented by the *Peronosporites antiquarius* of Worthington Smith. There seems little reason for doubting that this is one of the Phycomycetous Fungi, possibly somewhat allied to the *Saprolegnieæ*; but since we have as yet no evidence respecting its fructification, these closer relationships must, for the present, remain undetermined.

That marine plants of some kind must have existed simultaneously with the molluscous and other plant-eating animals of Palæozoic times is obviously indisputable. But what those plants were is another question. The widest differences of opinion exist in reference to many of them. A considerable number of those recognised by Schimper, Saporta, and other palæobotanists, are declared by Nathorst to be merely inorganic tracks of marine animals - and in the case of many of these I have little doubt that the Swedish geologist is right. Others have been shown to be imperfectly preserved fragments of plants of much higher organisation than Algæ, branches of Conifers even being included amongst them. I have as yet seen none of Carboniferous age that could be indisputably identified with the family of Algæ, though there are many that look like, and may probably be, such. The microscope alone can setttle this question, though even this instrument fails to secure unity of opinion in the case of Dawson's *Prototaxites*, and no other of the supposed seaweeds hitherto discovered have been sufficiently well preserved to bear the microscopic test; hence I think that their existence in Carboniferous rocks can only be regarded as an unproved probability. Mere superficial resemblances do not satisfy the severe demands of modern science, and probabilities are an insufficient foundation upon which to build evolutionary theories. Seeing what extremely delicate cell-structures *are* preserved in the Carboniferous beds, it cannot appear other than strange that the few imperfect Fungoid relics just referred to constitute the only terrestrial cellular Cryptogams that have been discovered in the Carboniferous strata. The Darwinian doctrine would suggest that these lower forms of plant life ought to have abounded in that primæval age; and that they were capable of being preserved is proved by the numerous specimens met with in Tertiary deposits. Why we do not find such in the Palæozoic beds is still an unsolved problem. The Vascular Cryptogams, next to be considered, burst upon us almost suddenly and in rich profusion during the Devonian age; they are equally silent in the Devonian and Carboniferous strata as to their ancestral descent.

The older taxonomic literature of Palæozoic Fern-life is, with few exceptions, of little scientific value. Hooker and others have uttered in vain wise protests against the system that has been pursued. Small fragments have had generic and specific names assigned to them, with supreme indifference to the study of morphological variability amongst living types. At present the study of fossil ferns is affording some promise of a newer and healthier condition. We are slowly learning a little about the fructification of some species, and the internal organisation of others. Facts of these kinds, cautiously interpreted, are surer guides than mere external contours; unfortunately, such facts are, as yet, but few in number, and when we have them we are too often unable to identify our detached sporangia, stems, and petioles with the fronds of the plants to which they primarily belonged.

That all the Carboniferous plants included in the genera *Pecopteris*, *Neuropteris*, and *Sphenopteris* are ferns appears to be most probable: but what the true affinities of the objects included in these ill-defined genera may be is very doubtful. Here and there we obtain glimpses of a more definite kind.

That the coal-measures contain the remains of arborescent ferns has long been known, especially from their abundance at Autun. In Lancashire I have only met with the stems or petioles of one species preserving their internal organisation. The Rev. H. H. Higgins obtained stems that appear to have been tree-ferns from Ravenhead, in Lancashire, and it is probable that most of the plants included in the genera *Psaronius*, *Caulopteris*, and *Protopteris*, are also tree-ferns.

Nearly all the Calamitean fossils found in shales and sandstones consist of an inorganic, superficially fluted substance, coated over with a thin film of structureless coal (see "Histoire des Végétaux Fossiles," Vol. I., pl. 22), *the latter being exactly moulded upon and following the outlines of the inorganic fluted cast that underlies it.* Brongniart and those who adopt his views believe that the external surface of this coal-film exactly represents the corresponding external surface of the original plant. Hence the conclusion was arrived at that the plant had a very large central fistular cavity surrounded by a very thin layer of cellular and vascular tissues as in some living Equisetums. On the other hand, Brongniart also obtained some specimens of what he primarily believed to be Calamites, in which the central pith was surrounded by a thick layer of woody tissue arranged in radiating laminated wedges, separated by medullary rays. The oxygenous structure of this woody zone was too obvious to escape his practised eye. But, not supposing it possible that any Cryptogam could possess a cambium-layer and an exogenous mode of development, Brongniart came to the conclusion that the thin-walled specimens found in the shales and sandstones were true *Equisetaceæ*, those with the thick woody cylinders being exogens of another type. His conclusion that they were Gymnosperms was a purely hypothetical one, justified by no one feature of their organisation.

My researches, based upon a vast number of specimens of all sizes, from minute twigs little more than the thirtieth of an inch in diameter, to thick stems at least thirteen inches across, led me to the conclusion that we have but one type of Calamite; and that the differenes which misled Brongniart are merely due to variations in the mode of their preservation. It became clear to me that the outer surface of the coaly film in the specimens preserved in the shales and sandstones did *not* represent the outer surface of the living plant, but was only a fractional remnant of the carbon of that plant which had undergone a complete metamorphosis; the greater part of what originally existed had disappeared, probably in a gaseous state, and the little that remained, displaying no organic structure, *had been moulded upon the underlying inorganic cast of the medullary cavity.* This cast is always fluted longitudinally and constructed transversely at intervals of varying lengths. Both these features were due to impressions made by the organism upon the inorganic sand or mud filling the medullary cavity whilst it was in a plastic state, and which subsequently became more or less hardened; the longitudinal grooves being caused by the pressure of the inner angles of the numerous longitudinally vascular wedges, and the transverse ones partly by the remains of a cellular nodal diaphragm, which crossed the fistular medullary cavity, and partly by a centripetal encroachment of the vascular zone at each of the same points. My cabinets contain an enormous number of sections of these plants in which the minutest details of their organisation are exquisitely preserved. These specimens, as already observed, show their structure in every stage of their growth, from the smallest twigs to stems more than a foot in diameter. Yet these various examples are all, without a solitary exception, constructed upon one common plan.

At the meeting of the British Association at Liverpool in 1870, I first announced that a thick, secondary, exogenous growth of vascular tissue existed in the stems of many Carboniferous cryptogamic plants, especially in the Calamitean and Lepidodendroid forms. But, at that time, the ideas of M. Brongniart were so entirely in the ascendent, that my notions were rejected by every botanist present. Though the illustrious French palæontologist knew that such growths existed in *Sigillariæ* and in what he designated *Calamodendra*, he concluded that, *de facto*, such plants could not be Cryptogams. Time, however, works wonders. Evidence has gradually accumulated proving that —with the conspicuous exception of the ferns—nearly every Carboniferous Cryptogam was capable of developing such zones of secondary growth. The exceptional position of the ferns still appears to be as true as it was when I first proclaimed their exceptional character at Liverpool. After thirteen years of persevering domonstration, these views, at first so strongly opposed, have found almost universal acceptance. Nevertheless, there still remain some few who believe them to be erroneous ones.

After referring at some length to the botanical relations subsisting between other plants, pointing out that great progress has been made in our knowledge of Gymnosperms, that Cycads predom

AN [illegible] AND [illegible]

A [illegible] a brilliant [illegible] has been [illegible]-street, [illegible]. There is [illegible] white or [illegible] known as [illegible] soap, and [illegible] sufficient heat [illegible] in about [illegible] of the [illegible] yellow [illegible] sixth of [illegible] is dissolved [illegible] spirits of [illegible] these solvents, [illegible] reduce the [illegible] pasty condition. A [illegible] of beeswax is added to render [illegible] lustre or [illegible]. In order [illegible] citron[illegible], attar of [illegible] is added.

[illegible] ready for use, [illegible] will still re[illegible] it may be applied to [illegible] without requiring [illegible] with other materials. It is [illegible], or imparting [illegible] made of leather; but it may be used with advantage for polishing furniture, and, for this purpose, the vegetable black is omitted from the mixture. It may also be used for imparting a [illegible] appearance to articles made of papier-mâché, or [illegible] other articles or materials.

DR. D. T[illegible] states that if anthracene is dissolved in benzol and exposed to the direct rays of the sun, it becomes turbid and deposits crystals. This [illegible] substance has been named paranthracene. If melted it is reconverted into anthracene.

SCIENTIFIC NEWS.

THE comet, the discovery of which by Prof. Lewis Swift we announced last week, p. 60, is mentioned in the Dun Echt Circular No. 81; but at the date of issue it had not been observed by any one else. The same circular contains observations of comet *b*, 1883, which, it is thought, may possibly be Comet Pons of 1812, made at Leiden, Rome, and Dun Echt. MM. Schulhof et Bossert's elements and ephemeris are given in Circular No. 82, from which we find that the calculated position of Comet Pons-Brooks for Sept. 29 is R.A. 16h. 26m. 40·94s.; N. Dec. 59° 13' 41·0", Berlin midnight. The comet will remain above the horizon for some time, and during the moonless evenings now prevailing, will be within reach of telescopes of moderate power.

The next meeting of the British Association will be held at Montreal, commencing on August 27, 1884, Prof. Lord Rayleigh being the president elect. The American Association meets at Philadelphia on Sept. 3, 1884, and will welcome all visitors belonging to the British Association by placing them on the footing of members. Sir C. Tupper assured the general committee last Monday, that nothing would be wanting on the part of the Canadians to show how highly they appreciated the honour of the visit. The Canadian House of Commons has voted the sum of £4,000 to defray the expenses of receiving the Association, and the steamboat and railway arrangements for making long excursions are on an exceptional scale of liberality. The following names are given as probable vice-presidents:—The Marquis of Lansdowne, the Marquis of Lorne, Sir C. Tupper, the Hon. Sir A. Galt, Sir N. Dorion, Principal Dawson, Dr. W. H. Hingston, Dr. T. Sterry Hunt, Prof. Huxley, Prof. Frankland, Sir W. Siemens, and Sir L. Playfair.

Aberdeen has been chosen as the meeting-place in 1885, the only other town seeking the honour being Bournemouth.

The recent meeting of the American Association was not altogether a success, as the attendance was anything but large,—the distance of Minneapolis from the centres of scientific thought being too great to tempt many to leave their homes.

On Monday, at the British Association, a paper, the production of two authors, was read, in which it was stated that no really practically efficient secondary battery had been produced: and which described a new combination of boiler and coke oven, by which the value of the coke obtained equalled that of the coal used, and so the steam was obtained free of cost!

The death of the distinguished physicist, M. Joseph Antoine Ferdinand Plateau, is announced as having occurred in his eighty-second year. The deceased was Emeritus Professor at Ghent, and was a member of the principal learned societies of Europe.

Mr. Werdermann, the inventor of the well-known semi-incandescent lamp which bears his name, died the other day at the comparatively early age of 55 years. He came to London in 1870 on the breaking out of the war, and brought with him the first Gramme machine introduced into England. He owned, we believe, the English and American patents for that machine, and was a most ingenious inventor of electrical appliances, but lacked the "business" qualities which enabled others to become rich at the expense of shareholders.

Baron Nordenskjold, in the *Sophia*, arrived at Thurso last week, and lost no time in telegraphing that his views as to the interior of Greenland were not supported by the facts. Parties of Laplanders were sent as far as possible into the interior, where they found nothing but snow and ice. "Masses" of fine dust, partly of cosmical origin, occur with the ice. The Laplanders had to proceed on snowshoes, as the snow was too soft for sledges. Baron Nordenskjold says that the glaciers of the east coast are few, and of no great size, and that the fiords are free from ice.

The new Guion liner, *Oregon*, which is to leave Liverpool on her maiden voyage on October 6th, made an average of 20 knots during a long trial last week. The engines indicated more than the estimated 12,000 horse-power. If the *Oregon* can maintain her trial speed of 20 knots across the Atlantic she will about accomplish the westward passage in six days. We gave particulars on p. 404, last volume.

The "Facile" 24-hour road ride, accomplished by Mr. Adams the other day, puts into the shade all similar performances, as he covered 241¼ miles within the time, in spite of the rainy weather and some unavoidable delays while on the road. Deducting the time occupied in taking refreshments and rest, the average speed comes out at more than 11 miles an hour. The machine was a 44in. "Facile."

The "fungus hunt" of the Essex Field Club takes place in Epping Forest next Saturday (to-morrow), and the "cryptogamic meeting" will be held at the "Roebuck," Buckhurst-hill, in the evening, when interesting papers will be read by Dr. M. C. Cooke, F.L.S., Mr. W. G. Smith, F.L.S., and Dr. Wharton, F.L.S.

The *Liverpool Mercury* says that Mr. Banks, of Manchester and Blackpool, has produced a remarkable photograph of the Isle of Man hills, taken from the South Pier, Blackpool, a distance of 60 miles. The original was taken on May 17, the hills being discernible from Blackpool only at sunset in early summer, and was so small that it had to be many times enlarged to reach the carte size.

The Calcutta correspondent of the *Times* states that a remarkable phenomenon has been observed at several places in the Madras and Bombay Presidencies, and has caused much interest, mingled with not a little alarm among the superstitious. For some days the sun presented a distinctly green colour. Several explanations have been put forward, of which the most plausible appears to be that offered by the Government astronomer, that it is due to the passage across Southern India of clouds of sulphurous vapour from the Java volcanoes.

Under the auspices of the Gilchrist Trustees, a course of Penny Science Lectures is about to be given in the Royal Victoria Coffee Hall, Waterloo-road, S.E. The lectures, which are to be illustrated by the oxy-hydrogen light, and in the case of the first two by experiments as well, are to be as follows:—Oct. 2nd and 9th (two lectures), by Mr. W. M. Lant Carpenter, F.C.S., on "Ice, Water, and Steam." Oct. 16th, Mr. P. H. Carpenter, on "Life Under the Ocean Wave." Oct. 23rd, Mr. E. B. Knobel, Sec. R.A.S., on "Comets." Oct. 30th, Mr. C. A. V. Conybeare, on "The Rights and Feelings of an Animal." Nov. 6th, Dr. B. W. Richardson, M.D., LL.D., F.R.S., on "Food and Feeding." If the committee take care to make the lecture the chief feature of the evening, and do not relegate it, as in last year's experiments, to the fag-end of a miscellaneous entertainment, there seems no reason why Penny Science Lectures should not prove as successful and popular in London as they are in the North of England.

Messrs. Macmillan and Co. have made a new departure in English magazine literature with their "English Illustrated Magazine." The printing is excellent, the illustrations perfection, and the price a marvel. The list of contributors to the first number is a list of giants. Mr. F. W. Maitland on the Old and New Law Courts; A. C. Swinburne, Grant Allen on the Dormouse. J. Comyns Carr on Rossetti's Influence on Art; William Black with a story; Professor Huxley on the Oyster; and the first instalment of a novel by Charlotte M. Yonge, together make up a first number which, in literary value, has never probably been approached.

Dyeing Cut Flowers.—It has for a long time been known that the colour of growing flowers can be altered by simply mixing a little dyestuff with the mould in the flowerpot. No one, however, has hitherto thought of changing the colour of flowers when cut. We have in London many artists whose business it is to give to birds finer feathers than Nature has allowed them, and we have now a counterpart in flowers. Mr. Nesbit, a distinguished botanist, has found that by simply soaking the stems of cut flowers in a weak dye solution, their colour can be altered at will, without the perfume or freshness being destroyed. Most beautiful effects are produced by prepared lakes. Singular to say, flowers refuse to absorb certain colours, while they dispose of others in different manners. If placed in a mixed solution they make a complete analysis, and some lilies which had been treated with purple showed distict red and blue veins, the colours having been divided in the process of absorption.—*The Dyer.*

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, 31, *Tavistock-street, Covent-garden, W.C.*

All Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original."—*Montaigne's Essays.*

THE ANTIQUITY OF MAN—STARS VISIBLE IN A 9in. REFLECTOR—APPARATUS FOR OPTICAL EXPERIMENTS—THE OTHER SIDE OF THE MOON—THE INTRODUCTION OF CHRISTIANITY INTO BRITAIN—THE STUDY OF METAPHYSICS.—THE SOLAR CORONA—A PENNY WATER-CLEANER—COMITES TO VEGA—FORMS OF LENSES FOR LEAST ABERRATION.

[21850.]—THE concluding portion of the address of Principal Dawson, which you reproduce on p. 33 *et seq.*, seems to me to lead to one of two conclusions—either that its author is in curious and inexcusable ignorance of the European evidence which shows man to have been pre-glacial upon the earth, or that he is guilty of a deliberate *suppressio veri.* It is simply untrue that "Recently the opinion has been gaining ground that the close of the ice age is very recent" (using the words "very recent" in the sense in which Mr. Dawson obviously intends that they shall be accepted)—at all events, in this country. Just, however, as proverbially any stick will do to beat a dog with, so, in the opinion of an extremely small and insignificant school of geologists, will any argument—or assertion—suffice to show that it was not until "six or seven thousand years ago" that man first appeared upon the face of the earth. The quasi-laudable motive which prompts so gross a misrepresentation of fact is apparent enough; but, as a man who has devoted his whole life and no inconsiderable part of his fortune to the pursuit of science, I must protest against scientific falsehood being advanced to bolster up any theological system whatever. Anyone liable to be misled by Mr. Dawson's specious untruths may with advantage read Sir Charles Lyell's "Antiquity of Man" as a corrective, merely in matters of fact.

Mr. Holmes (letter 21797, p. 37) will find that Browning says (in his "Plea for Reflectors") that reflecting telescopes "in light-grasping powers . . . are equal to an achromatic one-sixth less in diameter." Adopting this formula, a 9in. reflector would have its equivalent in a 7·5in. refractor; the *minimum visibile* of which is the 13·6th magnitude of Argelander. Your correspondent ought to see such objects as the 4th star in β Equulei, or the minute pair between β^1 and β^2 Capricorni easily enough, even in London, on a fine night.

"Physis" (query 51658, p. 46) cannot do better than procure the little book on "Light," by Mayer and Barnard, in the "Nature" series. It contains illustrated descriptions of the most simple apparatus for exhibiting the reflection, refraction, and decomposition of light, so very plainly worded that its perusal would supply your querist with exactly the information he requires.

"The discovery" (if such it be) that the centre of gravity and the centre of figure of the Moon were not coincident, to which "W. G. C." refers in query 51684, p. 46, was first published by Hansen, of Gotha, in the year 1856 (R. A. S. *Memoirs*, Vol. XXIV., p. 31.) Taking the distance from the earth to the centre of figure as 1, he deduced the distance to the centre of gravity as 1·000154. In an editorial footnote on p. 276 of the second volume of the English edition of Arago's "Popular Astronomy" it is astonishingly stated that Hansen found that certain irregularities in the Moon's motion "would be almost wholly accounted for by supposing the centre of gravity to be situated at a distance of 1,740 miles (!) *beyond* the centre of figure," which, remembering that the Lunar radius is only 1081·53 miles, would place her c.g. outside of her altogether by some 660 miles!!! What Hansen really di contend for was that the Moon's centre of gravit was 33 miles farther from us than the centre of h longest diameter, and that this humped figure necessary to explain the irregularities spoken

observational astronomy may be organised: so much may be secured by combination, no matter how unskilled the observer may be. Indeed, the council of the society have welcomed the most humble efforts at observation, believing that there are many beginners to whom a little direction and assistance would be of the greatest value. And this is the reason of the marked success of the society, and the cause of the steady increase of members during last session.

The new session opens with prospects of even greater success. The list of new members to be proposed is a large one, and the promises of papers are very numerous. From every side the most cordial support of well-known astronomers has been received. The great object the council have had in view is to keep the subscriptions as low as possible, in order that no one may be prevented from joining. In spite of the comparatively small number of members, and thanks to the devotion of some of those members, the society commences its new session free from debt, I hear. Of course, the more numerous the members the more secure the society is from pecuniary difficulties. Indeed, a point must be shortly reached when the balance will be on the right side, and allow of sums of money being laid by for the foundation of a permanent observatory for practical astronomy.

I need hardly say what a cordial reception all readers of the ENGLISH MECHANIC receive, for we all remember that the idea of the society originated with some of "ours." **T. E. Espin.**

Observatory of the Liverpool Astronomical Society, West Kirby, Birkenhead, Sept. 17.

TRANSFER OF THOUGHT.

[21856.]—PROBABLY "Kappa" (21836, p. 67) is correct in saying we have had almost enough of this subject. A dicussion is rather difficult when it consists in one side bringing forward statements of facts demonstrated by careful observation, and in the other simply saying they do not believe such things can occur they are inconsistent with the notions they have formed, or that someone else has published a different opinion, and so on.

For instance, does "Kappa" think that it is legitimate argument, or even commonly civil, to say "even 'Sigma' has gone wrong," merely because he cannot see the truth I have attained to? I have given clear statements of *facts which I have observed* and carefully analysed, and I think I am perfectly capable of careful observation of facts, and that my opinions, based upon those actually observed facts, are likely to be more trustworthy than that of people who, not having witnessed the facts, refuse to believe them, or even to consider how far they are probable, merely because they differ from their own prejudices. If I stood alone, there might be some reason in this; but what I say agrees with what is said by everyone who has really examined the facts. It is wholly those who have either not examined at all, or who have incompletely examined, who deny them.

"Kappa" givet us just the same common folly in witnessing the very interesting statement of Mr. Carter's experiments. He compares the old game in which *external assistance is given to the seeker*, and the result is due to the sharpness of the player in following that indication, to a case in which *no such assistance is given*, and then he commits the gross impertinence of *assuming fraud or trickery*. Now, my own actual experience in these matters enables me to say that those young ladies possess those natural qualities which I explained years ago as constituting the "seer" or receptive constitution. I am perfectly certain that, under proper management, they would read the contents of a sealed letter, such contents being known to the person holding it, and such person honestly fulfilling, and being capable of fulfilling, the conditions. It is because all these different conditions must unite, and that they are all and each of them rarely found, that it is so difficult to obtain experimental evidence of the higher forms of thought transfer. And such evidence is powerless where people are determined to assume fraud and conspiracy in the parties to the experiment, and credulity and eagerness to believe in the observers. However, I am well aware that the facts are becoming widely known and deeply interesting to many, and I believe the evidence I have been able to give has made a great many people recognise that there is an important and unknown power in our nature, deserving of serious thought and investigation: so I care very little for the opinions of those whose mental eyes being unable to bear the light of truth, prefer to shut them.

Now, in reply to "F. W. H." (21837, p. 66), I have never said a word against scientific investigation, or denied the right to find out physical causes, &c. What I have protested against is the denial of facts and refusal to look at them. No cientist has ever yet given the faintest evidence that thought *is* a motion of molecules of matter. All that anyone has shown is that such a motion is an accompaniment of thought. But he is a presumptuous man, and not a scientist, in that respect, who asserts as a fact what is nothing more than his own prejudice—for it is prejudice. Those who assert this statement as to thought, go to their investigations determined to seek support for the pre-judged opinion. But all their facts are just as well explained as consequences of thought—as actions accompanying thought, not as being the agent.

As to the P. S., I beg to remind "F. W. H." that it was not *the* writer of old who *also* says that "man has no pre-eminence above the beast." The statement I referred to was by a different writer, and by one of a very different order of mind. It is very uncertain who was the writer of "Ecclesiastes," and it is considered that it was written during a period of national degradation and individual hopelesness. In fact, it is an early example of the lately revived doctrines of Pessimism, and of the question "Is life worth living?" Now, that question has been answerd by a pun: "It depends upon the liver." It does: if a man is a martyr to dyspepsia on the one hand, or if his mental and moral nature cannot rise above the mere animal routine, life is not worth living.

Now, if Solomon wrote "Ecclesiastes," he did it after he had ruined his constitution by excesses, and worn out his temper and spirits by squabbling with his thousand wives, and degraded his moral nature by conscious wrongdoing and idolatry, in defiance of his own wisdom. I do not attach the smallest weight to the dismal wailings of a man suffering from such a complication of physical, mental, and moral diseases. On the other hand, I am inclined to think that the writer (be he who he may) intended to paint the worst picture of life, such as it might be regarded by men either suffering under the evils of the most tyrannous and corrupt government, or the still worse evil government of their own utterly selfish passions. I think he did this with the deliberate intention of leading to the final teaching following those striking words: "Then shall the dust return to the earth as it was, and the spirit shall return to the God who gave it": words, be it seen, very inconsistent with the apparent sense of the parts from which "F. W. H." quotes, though even among them are to be found many a vivid gleam of higher and nobler thought. With all his apparent despair of life and doubt of man's nature, it will not do to quote the writer of "As thou knowest not the way of the spirit, nor how the bones grow in the womb of her that is with child, even so thou knowest not the works of God who maketh all," as a supporter of the "great German scientists" who pretend to know all about it, and deny the existence of that spirit because they know not its ways. It is not by taking isolated remarks that a writer's spirit is to be discerned.

Sigma.

[21857.]—"SIGMA," I hope, though he may think with me "Nihil humanum a me alienum esse puto" will accept the above advice from one who has passed the Biblical three score and ten some years, and which is offered *sine ire et odio*, and with the greatest regard for "Sigma's" distinguished talents in general, and as an electrician in particular. In talking of presumption and ignorance of other earnest investigators, "Sigma" descends below his level, and joins in the chorus of abuse heaped upon such men as Darwin, Huxley, Tyndall, Strauss, Rénan, Colenso, and a host of other inquirers after truth. I should be sorry to reckon "Sigma" amongst this class of thinkers, on which the simple mention of any of these great men acts as the dangling of a red rag before the eyes of a mad bull. I remember what a godsend it was to this class of men, when the existence of the famous "Acarus Crossii" was disproved, a fact asserted as such in that remarkable though well-abused book, "The History of the Vestiges of creation" (I believe generally attributed to Dr. Chambers). I often heard my friend Dr. Elliotson "piæ memoriæ" complain of the abuse he suffered because he was a believer in unpractised mesmerism, and of whom people said in contempt: "Oh! You mean the man who goes about with a piece of wood to apply to the chests of his patients." It would be difficult nowadays to find amongst the medical profession one who does not think this piece of wood an indispensable, great boon of "Laennec." But "revenons à nos moutons," as our neighbours say. Might I ask "Sigma" if he understands German, or if his knowledge of Moleschott is only second-hand, whom he accuses of presumption and ignorance for saying "Thought is motion of atoms"? Will he permit me to refer to another quasi-paradoxical saying of Moleschott which excited the gentle ridicule and sarcasm of Liebig—viz., "No thought without phosphor?" Yet, as far as I remember, this great chemist, though bad biologist, had the worst of the argument, after Gobley proved that the brain contains a fat which, treated by mineral acids, and alkalies, is decomposed into margarin and phosphor-glycerine; and Liebig himself acknowledges that the brain and nervin matter contain phosphor, without which their development is arrested, and thus Moleschott's dictum, "No thought without phosphor," seems justified. Du Bois-Reymond, whose work on animal electricity "Sigma" no doubt knows by heart, was, I believe, the first who proved that in all nerves an electric stream is present. Nerves are the cause of the shortening of the muscular fibres which result in *motion*. Nerves are the mediators of all sensations. Impressions arrive only at consciousness when they are transmitted to the brain. Du Bois-R. further asserts that every action in the nerves, which in muscles effects motion, is perceived in the brain as sensation, and is accompanied by a change in the electric state of the nerves. In the moment of motion or sensation, the electric stream suffers a diminution, produces a chemical change in the conducting medium, similar as we decompose water into oxygen and hydrogen by electricity—every change in the state of the nerves involves a change of its atoms. Davy and Bärensprung affirm that mental activity causes hunger, and augments the breath of the body. Hunger is a sure sign of wasted powers, of poverty of the vital fluid, which cannot otherwise be explained, as by an increased metamorphosis of elements, due to a heightened activity of the brain during the strain of thinking. While awake, a greater mass of blood circulates in the brain than when asleep; observe the head of an infant while asleep. The fontanel appears as a great depression, while, when awake, it appears quite *arched*, on account of the increase in the blood of the brain. In fact, every increase in the function of an organ is due to a greater influx of blood to this organ. During digestion, the stomach is in a state of congestion as it were, and on its completion, a reflux through the venæ breves to the spleen takes place. Thus, Moleschott came to say "thought is a motion of matter." During thought, the brain becomes a centre of attraction for the circulation, and with it a more active change and metamorphosis is the necessary consequence.

Continuing your lecture of Mr. Craven, I might say, and say truly, we do not see the objects themselves, which might seem strange to the uninitiated. My clinical teacher in 1828 already talked of food for the lungs, in anticipation of what now every schoolboy accepts as reasonable. V. Hardenberg ("Salis" the poet) defined philosophy as a desire to be everywhere at home. Nobody would take this as meant for a proper definition—yet it was the thoughtful expression of an amiable poet. I should have thought thus also Moleschott's expressions might have passed without exciting ire and obloquy. Give to everybody credit for an honest desire of arriving at the truth. I often think what a good thing it is that the highest problems of humanity are involved in doubt, thus stimulating the noblest minds to find a solution of them as far as they are able; without this, there would be but a stagnant pool of decay. Even in the presidential address of Professor Cayley the old vexed question of innate ideas of time and space, which we discussed as schoolboys, return as objects for discussion, and will return as long as the world is as we find it.

Apologising for the length of these remarks—you know old men are garrulous: but I will promise to bear any punishment that may be in store for me meekly, and not enter on any discussion.

September 25. **F. D.**

[21858.]—DOES "Sigma" (letter 21712) mean to say that ether and chloroform have the same effect as mesmerism? Do they not act on us in a measure so as to stay the circulation, and is it not the case that sometimes the heart is too weak to put things right again, and so the patient dies? In fact, do they not really act by partly destroying life, and does not the pulse tell one so? Is this the action of so-called mesmerism?

E. T. Scott.

[21859.]—THE dogmatic tone adopted by our valued correspondent, "Sigma," in the discussion on thought transfer has surprised me very much; and his statement that "all the Haeckels, Buchners, and Moleschotts put together will never convince me that any combination or motions of atoms of carbon, hydrogen, or nitrogen ever worked a problem in Euclid," can only be bracketed with the remark of the old woman, who said she was open to conviction, but would like very much to see the person who could convince her.

"Sigma" may, of course, believe that the phenomena of life and mind are due to an extra-material principle; but the conclusions of science do *not* favour that view. Will "Sigma" assert that botanists believe anything except matter exists in plants? Scarcely, I think; and if the phenomena of plant life can be produced by matter alone, why not animal life, even in its highest forms, as well? Go into a conservatory, "Sigma," sit down, and try to realise that the floral beauty around you is only matter. Look at a hyacinth bulb; remember that there is nothing in it except matter; think what it will do if planted; try to form some conception as to the molecular machinery of the bulb—I do not think you will succeed. I am doubtful as to whether anyone will ever succeed; but the exercise may at least teach you not to dogmatise on what matter can or cannot do. "Sigma" may argue that plants do not think: granted, but if the phenomena of life be once admitted as produced by matter, *there is no logical halting place*, no spot where we can say, "Behind this is only matter, but higher up is something else." Whether my friend likes it or not, whether it will square with his beliefs or not, and whether he will admit it or not, the fact remains that the tendency of modern investigation is to glorify matter, and to send the "vital fluid" to keep company with the caloric fluid, the electrical fluid, &c., in the invention of which the old schoolmen displayed such fertile imagination, and such utter lack of experimental knowledge. Of course, we do not know *how* the brain thinks: but it will be quite time enough to attempt that problem when we have learnt *how* sugar is sweet, acetic acid sour, bichromate of potash red, and chrome alum violet-green. We do not know the *how* in any of these cases, but no one (excepting now and then an elementary science student) thinks there is a principle of sweetness in sugar or of sourness in acetic acid. The fact that we cannot understand how the brain thinks has no argumentative value whatever; in attempting to understand it we are probably [illegible] into the position of an express engine trying to comprehend the cause of its own splendid strength.

In conclusion, I would like to intimate to "Sigma" my regret at the [illegible] he seems to have taken up, and to assure him that a desire for further truth is my only object in writing.

Wm. John Grey.

Elswick [illegible] School.

TRANSFER OF THOUGHT—TO MR. CARTER

[illegible]—[illegible] appears to be aware that children [illegible] very quickly [illegible] a single [illegible] and [illegible] two fingers [illegible] each [illegible] your friend is [illegible] I know of a case where a [illegible] certain letters of the [illegible] thumb and fore- [illegible] of this kind.

K.

[illegible] at the remarks of "Sigma" [illegible] about his [illegible] scientific [illegible] of scientists as [illegible] world works, and [illegible] scientists [illegible] their so-called [illegible] and more important [illegible] stated by "Sigma" as ascertained [illegible]

It is equally useless to pervert the sense of the argument of an opponent, which "Sigma" certainly endeavours to do in stating "if certain views be true, &c., there can be no thought at all." In all the writings of Moleschott there is not a line from which such a conclusion could be logically drawn. The very words quoted declare not that thought cannot be, but the means of its origination are referred to motion in matter (brain matter).

F. W. H.

[illegible]—INTELLIGENT readers of the ENGLISH MECHANIC will regret that so much valuable space has been taken up by "Sigma" in explaining that which we all learned in our schooldays. (21835) "Sigma" tells us that a man loses sight if a cataract forms; (2179?), also, that one cannot see in a mesmeric trance, with the eyes closed, and the eyeballs turned up to the skull; (21712) and yet, he says, it is possible, under "certain conceivable conditions," to see with the tips of our fingers; [illegible] surely it would not be difficult for one who has "lifted the veil of a tremendous mystery" [illegible] to explain [illegible] these "conceivable conditions" [illegible], and thus settle the matter.

T. E. D. Craven.

[2186.] I ATTENDED some experiments in thought reading which had interested me, and "Kappa" [illegible] comes forward to explain that I have been imposed upon. But if this covers my case, it will cover the thousand and one precisely similar which happen every day; so cease your [illegible], "Sigma," and the rest. A Daniel has come to judgment, to teach you "how it is done." It is all a matter of "tapping." One tap, "you're cold"; two taps, "you burn"; three taps, "you've got it," or, at least, you should have, according to the [illegible] authority. Here is [illegible] [illegible]. *But will "Kappa" go a little more into detail,* as I do not even now quite understand. The children to whom I have alluded, and to whom I read "Kappa's" letter on Saturday evening, much to their amusement, tell me that so far from being peculiar to themselves, the exception is to find anyone who cannot do it, and they named half a dozen friends whom I know, and who have tried it since I saw them, with perfect success. Now, if it is a case of auctioneer's "tapping," each of these, as well as themselves, must have been instructed in the code of signals before commencing: but as there would be only themselves to be amused, and each would be in the secret, the fun must be rather slow. My young relations make it an evening amusement among themselves when they are quite alone: but it would seem a little absurd for one to be tapping when all could do it alike. It is as if three or four conjurors should get together one evening to exhibit the feat of legerdemain which are the common stock in trade of all. Then, again, as I suggested what should be done in the absence of the child, and not a word was spoken after her return, it is strange that the taps which must have been audible to her, should have been unheard by me: perhaps, however, they were peculiar—"Kappa taps," I may call them—which could not be heard. And Jack's "private signal with her sisters" is also greatly in need of explanation, for I blindfolded and led her out of the room, and how, in the deep silence, she was made to understand that I had put a thimble in a box in her absence, is a mystery which only "Kappa" can fathom.

I am almost ashamed of refuting these absurdities, for I must repeat that "Kappa" must mean them for a general explanation of the phenomena. The children have exhibited the power to many besides myself, and others, to their surprise, have done the same things. Here are men like Tyndall or "Sigma," engaged in an earnest inquiry, under conditions to preclude imposture, into this matter of thought reading, and in comes this flippant "Kappa," who probably has never given half an hour's consideration to the subject, and explains all by the Christmas game of "Auctioneer!"

The courteous suggestion of "Sigma" in the last number, that the results I described (21805) should be tested without contact with the subject, has been acted upon, but without success. It may be due to an imperfect mode of applying the test. I did not witness it, but was told it did not succeed. The slightest contact, however, of one person is sufficient for the purpose.

"Sigma's" suggestion that unconscious muscular guidance may account for the phenomena, is very likely correct, but it does not seem to me to cover all the facts, for if the direction of the subject is thus caused, the hands and arms are free and unrestrained, and the action of the subject appears to be spontaneous. As an experiment the other evening, I hid a thin card under the cloth of a large dining table, which I willed the child should find and place under a newspaper on another table. She walked round the table twice, stopping at length near the place where the card was concealed; but on the hypothesis advanced, I do not see why she should have made the second journey. I shall be glad, however, to accept any explanation which does not insult common-sense, like the suggestion of "Kappa," to which I have separately referred. I may add that the thing alluded to was done, as also another, which bordered on the ludicrous. I suggested that one of the other children who was absent from the room should, when blindfolded, take a piece of sugar out of a basin, place it first on the sill of the open window, and then throw it out. Everything was done exactly as I had willed, and as the child dropped the piece of sugar into the garden after its temporary rest on the sill, she exclaimed, "What a waste"!

T. H. Carter.

[21861.]—I was just going to the house of a friend on Friday evening last when I read, in the "E. M.", the interesting letter of Mr. T. H. Carter, No. 21805, and as we were to have a performance of a very similar character, I thought you might be interested in a few notes upon the subject. The *Notes* were taken by a bank teller who was present. I am the Congregational Minister referred to, and gladly offer my testimony to the accuracy of the notes. The blindfolding was done by ourselves, and consisted of a strip of black cloth cut with a bridge for the nose, so that the side pieces could hang down upon the eyes and cheeks. Over this a silk handkerchief was carefully bound. No word was spoken while the girl was undergoing the tests, and the father was carefully watched to see that he gave no hint or help of any kind to his daughter. The child is an interesting and well behaved girl, the daughter of a working man in Manchester. Her education has only been such as such girls usually get. The entertainment was got up by a gentleman of well-known character and probity in the neighbourhood, and who is well known in Manchester, his object being to afford himself and a few friends a quiet opportunity of judging for themselves. In every case the tests were entirely successful as described, especial praise being due to the skill—or whatever it is—with which she read the cards upside-down and put them perfectly straight in their places.

The Congregational Minister.

Sept. 18, 1883.

Notes of an Exhibition of Thought Transfer, Second Sight, &c., given by Miss Lilian B. (age 11 years), at the residence of J. B., Esq., on Friday evening, Feb. 14.

Present, a party of 19 ladies and gentlemen, including a Congregational minister, a doctor of medicine, a bank manager and two gentlemen of considerable experience in legerdemain—all anxious for honest investigation and keen to detect trickery.

The performer was carefully blindfolded, and in her absence it was decided that the first tests should be (1) An indication of the position of the ladies in the room, and also of all the bald-headed gentlemen. (2) A jug filled with water was to be placed upon the table—also a glass—and a gentleman was to be selected to whom the glass of water should be offered.

Result—On being brought into the room blindfolded, and without being in personal contact with anyone, the performer (1) pointed to all the ladies in the room; (2) indicated the baldheaded gentlemen (three in number); (3) found the jug and glass; (4) filled the glass with water; (5) and handed it to the gentleman who had been selected. Time 7 minutes.

Again Miss B. was conducted out of the room. A rack or stand covered with black velvet was then placed upon the table, and on the top ridge (which was quite six inches above the level of the performer's eyes) letters were placed representing the word *Albert*, which had been chosen by those present. Over 200 letters were then thrown down indiscriminately upon the table, face upwards.

Result—Miss B. advanced to the table, picked out in succession from the heap of letters A L B E R T, and placed them on a ridge of the stand immediately under the letters already placed there by the company. No personal contact again. Time 5½ minutes.

The name of the town was then chosen, but not placed upon the stand, and more quickly than before the letters forming the word were picked out from the heap and put upon the board by the performer. With a view to disconcert her, the letter O was removed from the word she was forming, but the blank space left by the missing letter was noted at once. Time 4½ minutes.

It was observed that Miss B. placed the Y (one of the letters of the word) upon the board before the E, but she did not fail to leave an open space for the insertion of the E. The only explanation of the Y being used first was that it happened to be observed first from amongst the letters on the table.

A hand at whist was decided upon as a further test.

On being brought into the room the performer (without being told where to sit) walked to the vacant seat left for her at the table.

The game proceeded and, blindfold, and without contact, she unhesitatingly played the right card whenever her turn came round—the result even under the strange condition of blindfoldedness, being that she and her partner won the hand. On being asked why she played a trump card she replied, "Why, to beat them!" Time, 9 minutes.

The whist test concluded, the 52 cards were spread out on the table face upwards, and the performer agreed to pick out any card named.

The Queen of Hearts was asked for and found in exactly two minutes. The eight of hearts in 3½ minutes. The spade ace in 1½ minute.

A more difficult test followed. The cards were arranged in suits and laid in rows on the table. Each row began with the ace (counted as *one*) and went on progressively according to the number of spots.

Four cards were taken up, here and there, from those on the table by four separate persons, and, after being well shuffled, were placed face *downwards* in the hands of the performer. Advancing to the table, she put the four cards back in their places without the slightest approach to a mistake. Time 3 minutes.

Having been taken out of the room, she was again admitted to find a concealed box of chocolate. The box was found without hesitation. Time 3 minutes.

After working hard for an hour and a half in this way, it was only natural that a child of eleven should complain of exhaustion, but she consented nevertheless to attempt the finding of a concealed pin *à la* Bishop. Twice in succession she found the *locale* of the hidden article, but did not attempt to pick it up, not apparently being quite sure of the object. The third time, however, when the pin was pricked into a black silk cushion and placed on the table, she found it without much effort, taking it up quickly and without hesitation between finger and thumb.

Everything during the evening was accomplished without the least personal contact. The only help (if help it be) was given to her by her father, who stood near (but never touched) her, and the assistance appeared to consist merely in the concentration of his mind and eye upon the various objects with which the child was dealing.

A PENNY WATER CLEANER.

[21865.]—THE writer is very much pleased with Mr. Fredk. Guthrie's-letter containing a description of the above. His remarks are very good and valuable. But it is possible that harm may be done if people were to allow the water to drop slowly direct from the service tap, as is so very easy to do. I will tell you how. Some time since, in a town not far from Manchester, a cotton mill operative and his family were taken ill; the doctor was called in; he was puzzled with certain symptoms which were very unusual among mill hands; he prescribed suitable remedies, but his patients got no better. During one of his visits he noticed the water regularly dropping from the tap, and being caught in a clean vessel. He asked what they did this for. "Because," they answered, "the water was so nice and clear; indeed, it is better than if filtered, and we always use it." The family were suffering from lead poisoning.

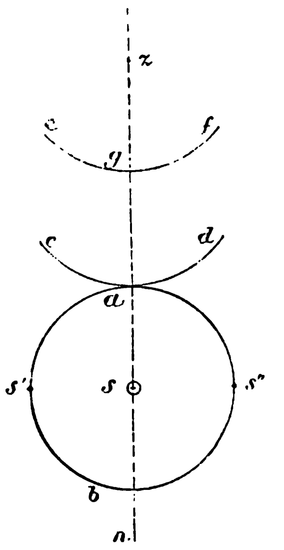
Any reader can easily avoid such an unfortunate occurrence. Lead pipes are often tin lined now, but I would not trust them as narrated above.

W. B.

PARHELIA.

[21866.]—YESTERDAY afternoon (Sept. 9th, 3.30 P.M.) I witnessed a parhelion of some peculiarity, which is perhaps worthy of being recorded.

In the subjoined diagram Z N represents a plane through the spectator to sun, S, and zenith. S′ S″ two mock suns, bright, and possessing slight prismatic colouring, red being in both cases towards the sun.



A B a circle of white light passing through the mock suns, and fainter at the bottom than the top.

C D a small portion of another circle of bright white light meeting the other circle at the point A.

At a distance A G, about equal to A S, was a portion of a third circle, E F, coloured like the rainbow, with the red towards the sun. This was very brilliant.

The centres of all the circles appeared to be in the plane Z N.

The diameter of the circle A B was about 25°. Long., 1° 14′ W. Lat., 60° N. Barometer, 30·025. Thermometer, 53. Wind, S., light. Weather fair. To-day Sept. 10th—Barometer, 29·850. Thermometer, 50°. Wind, S. E., fresh. Heavy rain.

Edward M. Nelson,
Sandwick, Shetland, N. B.

DR. EDMUNDS ON SCREW PITCHES.

[21867.]—IN Dr. Edmunds' recent paper on screw pitches, &c., in the *Journal* of the Amateur Mechanical Society, referred to in the first article of the ENGLISH MECHANIC for September 7, he reproduces from Holtzapffel's IVth volume a sketch of a male screw, a copy of which is shown here (Fig. 1), and states that it may be taken as Mr. Holtzapffel's ideal of a mandrel nose. It is difficult to conceive how Dr. Edmunds can have thought of doing that gentleman such an injustice. Mr. H., in giving general instructions for the formation of a screw on the lathe, draws attention to certain points, and, to illustrate his meaning, gives a rough sketch of a screw, in which these particulars are shown in a somewhat exaggerated form; but nowhere does he state that this is the form he approves of for mandrel noses, nor does it in the least resemble those supplied by the excellent firm of which he is the head. In Fig. 2 I give a sufficiently accurate sketch of one of Messrs. Holtzapffel and Co.'s mandrel noses, the proportions of which will be seen to be as different from those of Fig. 1 as one screw can be from another.

G. C. C.

Length	$\frac{37}{64}$
Diameter at top of threads	$\frac{52}{64}$
Do. bottom ,,	$\frac{[illegible]}{64}$

THE THEORY AND CONSTRUCTION OF THE HELIOSTAT.

II.—Constructive.

[21868.]—A HELIOSTAT on Fahrenheit's principle may be very simply constructed as follows:—

Cut out a piece of wood about 18in. by 12 for a baseboard. This should be clamped; that is, it should be constructed like a drawing board with pieces match-planed on to the ends to prevent warping. If this is thought difficult, cross pieces may be screwed on underneath at each end, but one or other of these methods must be adopted, or the board will infallibly cast and spoil the whole instrument.

Next cut a piece of hard dry wood an inch thick to the shape of Fig. 1. This may be about 5in. wide, and say 7in. high; the only important point is that the angle A should be equal to the co-latitude of the place. Thus, if you live in London, which is about lat. 51½°, the angle A must be 90° − 51½° = 38½.

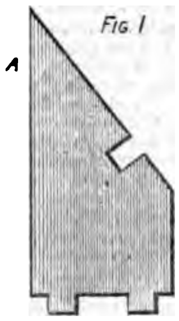

FIG 1

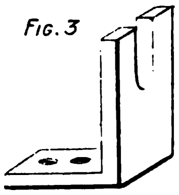

FIG. 3

Fix this piece to the baseboard by inserting the tenons into mortise holes, so that it may stand up at right angles parallel to one of the short sides of the baseboard and about 6in. from it.

Now take a piece of bright steel rod about ⅛ to ¼in. in diameter, and one inch longer than the slant side of the small piece of wood last described, and insert the end to the depth of about ¾in. into the end of a piece of wood of the shape of A B, Fig. 2, taking care that the hole is bored axially in the wood.

Next turn out of box, o some other hard wood, two small pulleys with V grooves, taking care that the diameter of one measured to the bottom of the groove is exactly double that of the other, and bore through the centre of the larger of the two a hole of such a size that it will drive tightly over the steel rod (see Fig. 2).

Now obtain a piece of good looking-glass, not too thick, and about 7in. by 3in., and attach to the back of it a piece of thin wood slightly larger than the glass, to enable you to fasten the looking-glass down to it with round-headed screws over the edge. To the middle of the back of this piece of wood fasten another piece of the shape shown in the figure. This is to be attached to the piece of wood at the end of the steel rod by a small thumb-screw, to be purchased at any ironmonger's. Fig. 2 will show the whole disposition. P is a small protractor fastened to the wood at the back of the looking-glass, and which will enable you to set the glass with sufficient accuracy. The glass is capable of being turned round the thumbscrew, and by it fixed in any desired position.

Now fasten on to the stout edge of the piece (Fig. 1) two little pieces of sheet brass of the shape of Fig. 3, so that the steel rod (which we will now call the "polar axis") may turn easily, the pulley dropping into the notch of Fig. 1. A small screw at the lower end of the slant side of Fig. 1 will keep the polar axis in place and prevent the pulley hanging against the side of the notch; and if the polar axis shows any disposition to overbalance, a small staple may be driven over it.

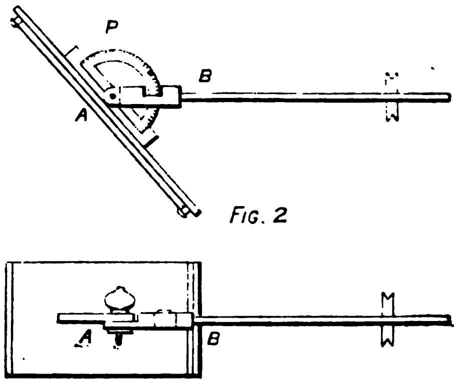

FIG. 2

Now fasten down to the unoccupied end of the baseboard a small American clock. This may be purchased at Clerkenwell (or through any watch-maker) for about 4s. 6d. Before fastening it down, however, drive on to the hollow axis of the hour hand the smaller of the two boxwood pulleys. A band of thin string or catgut will now put the whole thing into gear. It will be better, however, not to fasten the clock directly to the baseboard, but to an independent stand, with a slot in it, through which and a hole in the baseboard, a thumbscrew can be passed. This will enable you to regulate the tension of the string that the movement may be easy and without slip.

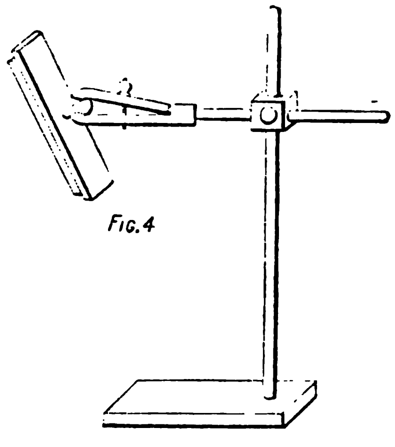

FIG. 4

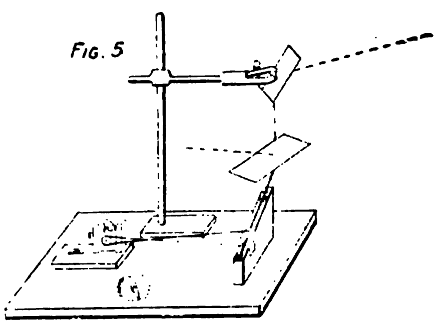

FIG. 5

If a clock with a pendulum be chosen, a hole must be cut in the baseboard to allow the pendulum to pass through, and the baseboard must be mounted lap of valve, to this add the required compasses to that distance and mark below line B and parallel to same, circle on each side, now from centre C and D, extending them to the edge, project these lines along and parallel position required, draw the centre line entries and put them on the shaft, lines to those on the shaft: this will position for forward and backward.

— **Pneumatic Tubes.**— Composition material you can use. This can be any gasfitter. If you have not a r you, it will be an easy matter to get ndon, Birmingham, or other large towns. NCASTER.

— **Signal Boxes.**—The signal boxes on Railway are provided by the telegraph with oval-shaped boards. They are ne and sometimes white on one side, and a white line across on the other side. If raph apparatus are in good order the shown, but if any defect occurs in the block instruments the board is shown

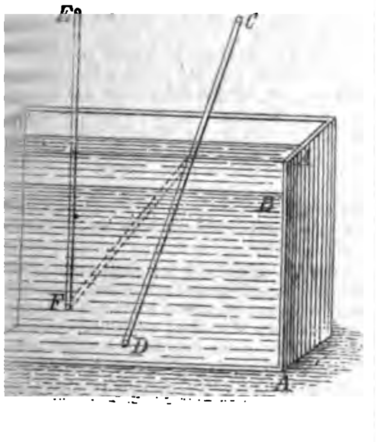
0

, &c., it is shown thus—

⬭

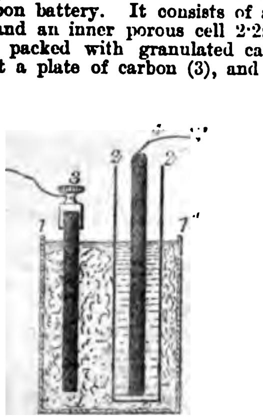
f these boards is to get the lineman's ho may go by in a train, and who keeps out for such evidence of any defect.— MAN.

Light.—You can make a very simple ting apparatus for exhibiting the re- light as follows:—Make a rectangular ack, ends, and bottom of wood, having a A A A A and with top open. Fill with



to the line B B. When placed on the ble the glass front should face the audi- lecturer takes the rod C, and passes it down into the water till it touches the bottom of at D. A second rod E is put in the hand of e audience with a request that he will, look- n from the top, indicate the position of the which he will do by placing the point of t F.—R. B.

.]—**A Three-Cell Battery.**—I should "Physis" to construct three cells of the carbon battery. It consists of an outer in., and an inner porous cell 2·2in. The ell is packed with granulated carbon, in is put a plate of carbon (3), and charged



a solution of bichromate of potash and iatic acid. The inner cell contains a zinc rod ylinder (4) in a solution of chloride of ammo- m and muriatic acid. Three of the cells (outer 10in. high) will light a 3 candle-power lamp. is battery requires recharging every five or six weeks: the old solutions should be thrown away, and the battery well washed in plenty of water before charging it with the new solutions. These cells can be sealed and used for electro-plating, firing fuses, working medical coils, electromotors, and for incandescent lighting.—ELECTRICIAN.

[51660.]—**Double Dark Slide.**—To MR. LANCASTER.—You shall have instructions with drawings in a week or so. Meanwhile, if there is any question you would wish answered, I shall be pleased to answer it. I am really sorry that my time is so limited, or rather that all of it is used up, and that I have to snatch a moment from sleep to write a short answer now and again. I would willingly write more and more, but at present it is quite an impossibility. The drawings of different parts of slides have occupied some time, and, if they were finished, I would send article on at once; but I promise you if I cannot finish the drawings this week, I will get a draughtsman to do them.—W. J. LANCASTER.

[51664.]—**Prepared Ferrotype Plates.**—To MR. LANCASTER.—You can prepare ferrotype plates, but cui bono, when you cannot produce a positive upon them? If you want to take negatives and transfer the gelatine on to glass, then the ferrotype plates may be used; but if you wish to take positives they are useless.—W. J. LANCASTER.

[51670.]—**Gravity and Equilibrium.**—There is no mechanical work done in keeping a weight of whatever magnitude in a fixed position.—WM. JOHN GREY, Elswick Science School.

[51670.]—**Gravity and Equilibrium.**—Let air = $\frac{1}{820}$th the density of water, and g = 32ft.; then it would take 62·577 horse-power to sustain 112lb. spread over 1 square foot of surface; but it would only take half the horse-power named if the 112lb. were spread over 4 square feet of surface, one-quarter if over 16 square feet, and so on. The principle being the same as that by which $\frac{1}{4}$, &c., "head" water will only give $\frac{1}{4}$ pressure, $\frac{1}{2}$ velocity, or $\frac{1}{8}$th work, and so on.—G. PINNINGTON.

[51679.]—**Indiarubber Gaspipe.**—Throw it away and buy the black indiarubber tube. This will not smell, and will last much longer than the common tube—W. J. LANCASTER.

[51686.]—**Christianity.**—The date of the introduction of Christianity into England cannot be accurately determined. It is known for a certainty that St. Alban was the proto-martyr for Christ in Britain, and that his death took place at Verulam at the beginning of the fourth century. Some authorities say that Christianity was professed in this country as early as A.D. 61; but much uncertainty prevails on the subject.—W. HENLEY RICHMOND.

[51687.] — **Railways Speed.** — The average speed of the Irish mail, and the Scotch limited mail is, as near as possible, between 39 and 40 miles an hour, including stoppages. Of the Highland express I know nothing.—MACHINA.

[51687.]—**Railway Speed.**—The average speed of (1) the Irish Mail, including stoppages, is $\frac{263}{395} \times \frac{60}{1} = \frac{263}{79} \times \frac{12}{1} = 39\frac{75}{79}$. Excluding stoppages it is $\frac{263}{367} \times \frac{60}{1} = 42\frac{366}{367}$ miles per hour. This is the train leaving Euston 7.15 a.m. (2) That of the Scotch Mail, including stoppages, is $41\frac{1}{430}$ miles per hour, and, excluding stoppages, $43\frac{71}{113}$. This is the train leaving Carlisle 8.46 p.m., which takes one minute less than the down mail. The Highland Express averages, including stoppages, $39\frac{3}{31}$; excluding stoppages, $42\frac{66}{427}$ miles per hour. The above are all upon the L.N.W. The Caledonian, between Carstairs and Carlisle, reaches an average of 48 on the up mail, and 43 on the "Highland." If "Euskarian" will turn to Bradshaw, he will find what he requires.—W. THOMPSON.

[51689.]—**Spectacles.**—The better thing for you to do is to go to some respectable optician who knows his business—I don't mean a simple spectacle seller—and get the glasses you require. From your description you ought to have two glasses of different foci, but the exact difference required it is impossible for me to tell you. You need not have glasses so deep as to enable you to see distinctly miles away, better wear those that give you sharpest definition 100 yards away; then get the natural accommodation of your eyes to do the rest. There are cases in which the eye becomes more convex with age, but they are rare; the majority of cases gradually getting less convex.—W. J. LANCASTER.

[51690.]—**Metaphysics** has been wittily defined as one man trying to explain something which he knows nothing about, to another man who cannot understand a word he says. Had you not better take up something useful?—WM. JOHN GREY, Elswick Science School.

[51692.]—**Photography.**—A good intensifier for over-exposed plates is—

Bichloride of mercury	1oz.
Distilled water	20oz.

Powder the mercury and dissolve.

After well washing the negative, place in a tray, and cover with above, and allow to remain until the negative appears white at the back. Wash for half an hour, and then place in a tray and cover with 3oz. water and 15 drops of ammonia; when the whole is black again, take out and wash well, and it is then finished.—P. J. DEBNAM.

[51694.]—**Lawn Tennis Court.**—I had an asphalte tennis court made which cost about £60, including the necessary excavation, 14in. of concrete. If "H. B." is charged £100 for simply a coat of asphalte, he must be, to say the least of it, the victim of some very unprincipled person. The work he requires ought not to cost more than £25 or £30 done by professionals, and perhaps less, if done by some local gas company. I shall be happy to give any more information I can, if "H. B." should require it.—K. W.

[51694.]—**Lawn Tennis Court.**—Perhaps the person from whom you purchased had intended to give the concrete another layer of a smoother type. It would be well to find out from him, if you could, what his intentions were as to this; as if too rough for you to use, it was also so presumably to him. What I would suggest would be to jag up the concrete that is there, and give it another layer of fine concrete to a good depth—say, 4in. or so—to prevent cracking or flaking. Any builder ought to be able to do this for you for far less than the sum you name. I should say that if you only have one playing space to do, he ought to do it very nicely for £10 or £15.—SEMPER FIDELIS.

[51695.]—**Pot Pourri.**—This is a mixture of dried flowers and spices not ground. Dried lavender and whole rose leaves, 1lb. each; crushed orris, $\frac{1}{2}$lb.; broken cloves, broken cinnamon, and broken allspice, 2oz. each; table salt, 1lb. We need scarcely observe that the salt is only used to increase the bulk and weight of the product in order to sell it cheap. There is a similar preparation, Olla Podrida.—(From "Art of Perfumery"—Piesse). —J. W. LONGFIELD, 111, Manningham-lane, Bradford.

[51695.]—**Pot Pourri.**—Put into a large china jar in layers the following ingredients, with bay salt strewed between the layers:—Two pecks of damask roses, part in buds and part blown; violets, orange-flowers, and jasmine, one handful of each; sliced orris-root, Benjamin and storax, two ounces of each; a quarter of an ounce of musk, a quarter of a pound of sliced angelica-root, a quart of the red parts of clove gillyflowers, two handfuls of lavender flowers, rosemary flowers, bay and laurel leaves, half a handful of each; three Seville oranges stuck as full of cloves as possible, dried in a cool oven, and pounded; half a handful of knotted marjoram, and two handfuls of balm of Gilead dried; cover all quite close. When it is uncovered the perfume is very fine. A quicker sort of sweet pot: —Take three handfuls each of orange-flowers, clove gillyflowers and damask roses; one each of knotted marjoram and lemon thyme, six bayleaves, one handful each of rosemary, myrtle, and lavender, half one of mint; the rind of a lemon, and a quarter of an ounce of cloves. Chop all, and put them in layers with pounded baysalt between up to the top of the jar. If all the ingredients cannot be got at once, put them in as you get them, always throwing in salt with every new article.—G. T. DENYER.

[51699.]—**Centre Board.**—In your case a simple and effective keel is easily fixed. Take a board of $1\frac{1}{2}$in. red deal, cut it to a segment, 2ft. to 3ft. base by 1ft. perpendicular; affix by two long bedscrews from inside. The keel may be taken off when afloat by withdrawing screws and plugging holes. —R. HANNEN.

[51699.]—**Centre Board.**—Get on board a sailing barge and ask the captain to put out his leeboards and explain to you the use of them. In the meantime you will be able to see about their construction, &c., which will do a youngster more good than a week's reading. He will explain all to you for a couple of glasses of grog.—A COUNTRY CHIP.

[51702.]—**To "The Kent Hermit."**—The information you require would occupy several numbers of this journal; therefore, I cannot give it. But it may probably appear in fragments in future numbers in reply to queries.—THE KENT HERMIT.

[51703.]—**Arithmetical.**—If, as I presume; the querist means a speed of 40 and 45 miles per hour respectively, the answer is 2·72min., for the faster train covers 440ft. per minute more than the other, and must thus occupy that time in passing the combined length of the two.—BETA.

[51703.]—**Arithmetical.**—The fast train moves through 3,960ft. per minute, the slow one moves through 3,520ft. in the same time; therefore the difference, or 440ft., is the distance gained in every minute, but the sum of the lengths of the two trains, or 1,200ft., is the entire distance which the fast train must gain on the slow one before it clears it. ∴ 440ft. : 1,200ft. :: 1min. : 2min. $43\frac{1}{2}$sec., very nearly.—EX-BLACKSMITH, Gorton Brook.

[51703.]—**Arithmetic.**—A train, 635ft. in length, traveling at a speed of 45 miles = 66ft. per second, overtakes another train, 565ft. in length, travelling at a speed of 40 miles = 58·6ft. per second showing a gain (in the former) of 7·3ft. per second. The combined lengths of trains 1,200ft., which [illegible] 7·3 [illegible] about 164secs., the time one train takes to clear the other.—Glasgow.

[51704.]—**Problem.**

Let x yards = length of wall built by A
100 − x " " " " B
Let y shillings = price per yard paid to A
y − 2 " " " " B
then x y = 160 [illegible]
and (100 − x)(y − 2) = [illegible]
Solving these equations we find x = 52·4[illegible]
y = [illegible]
E. F. L.

[51704.]—**Problem.**—This is more like a catch question than anything else. Solution: Since the money received by A and B [illegible] and since B receives [illegible] per yard for his work than A, therefore B [illegible] of the number of yards built by A. [illegible] yards built by A [illegible] yards built by B [illegible] = yards [illegible] shillings [illegible] = [illegible] per yard, and [illegible] per yard [illegible] the answers will [illegible] decimals.—[illegible].

[illegible]—**Sundial on Card.**—[illegible] E. M. [illegible] John Ha[illegible].

[illegible]—**Telephone Transmitter.**—The [illegible] works well [illegible] very well. By means of a switch [illegible] switched "off," and the [illegible] and receiver switched "on." You [illegible] anyone who has to do with [illegible]. Try to get some broken sticks [illegible] easily cut with a fret-saw and finished [illegible].—W. R. Ha[illegible].

[illegible]—**Electric Bells.**—You may add any [illegible] of same size. Don't [illegible] they will not work well together [illegible] them as nearly alike as you can. [illegible] and in future clean them once every three months. The zinc you have is evidently an impure sample.—W. J. Lancaster.

[illegible]—**Electric Bells.**—If you want more power, [illegible] of course add more cells. It is of small consequence what size or kind of Leclanche you use. Perhaps your zinc is cast, and, therefore, [illegible] it may be badly amalgamated, or your [illegible] may not be so good as it might be. [illegible]

[illegible]—**Padding Flute.**—The best way is to try the instrument after being corked up at the end with tobacco smoke, this will show any leakage. [illegible] As to pads, I use flannel, and when [illegible] whether two or three thicknesses [illegible] been used. I usually find that [illegible] to renew one key, it is best to pad all the [illegible] at once.—V[illegible].

[illegible]—**Removing Ink.**—Try some very dilute [illegible].

[illegible]—**Removing Ink.**—Solution of oxalic acid [illegible] at once. Solution of chloride of lime does the same.—R. A. R. B[illegible].

[illegible]—**Fluorspar.**—Fluorspar will not scratch window glass, but quartz will readily do so. [illegible] Put a little of the powdered mineral in a leaden spoon, add a few drops of sulphuric acid, cover with a piece of glass coated with beeswax, through which your name has been traced with blunt-pointed needle; now warm spoon gently (so as not to melt the wax), and if the mineral is fluorspar, the liberated HF will etch your name on the glass. Fluorspar, on account of its abundance, has but little commercial value. Its chief uses are, etching on glass, articles of virtu, and fluxing in smelting operations.—Ex-Blacksmith, Gorton Brook.

[illegible]—**Fluorspar.**—Fluorspar, fluoride of calcium, fluorite, blue john, amethystine, or topazine fluor, is a compound of calcium and fluorine CaF_2. It is found crystallised in large transparent cubes, white, pink, purple, and violet, in Saxony, Cumberland, and Derbyshire, and especially in the blue-john mine, Castleton, in the latter county. It is locally called blue john to distinguish it from black jack, a species of zinc ore. Ornamentally, it is used for turning vases, &c., the largest [illegible] vase in the world being in the Duke of Devonshire's sculpture gallery at Chatsworth. The Roman [illegible] of Pliny, are supposed to have been made from fluorspar. It is less valuable now than in former years, and I have read that some time ago it was worth £40 per ton "in the rough." It forms an excellent flux, hence its name, for metallurgical operations. When heated with sulphuric acid, or oil of vitriol, calcium sulphate and hydrofluoric acid are formed. This acid is used for etching on glass; but being highly corrosive and extremely dangerous, it must be kept in vessels of fluorspar, as it will corrode glass.—[illegible].

[illegible]—**Street Lighting.**—Sugg's, Bray's, Peebles', Borradaile's, and Thorp and Tasker's regulators for street lamps are all good. I would recommend the latter for ordinary lamps. For low-candle gas, use 4ft. and 5ft. regulators. For large lamps use Sugg's or Bray's triple burners with [illegible] service. For reflector use opal panes in lanterns.—W. T.

[illegible]—**Lantern Readings.**—The only way you can do what you want successfully is to take a lantern transparency of the bill, then show that; you may soak the bill in oil, or wax it, or mount it between two glasses with Canada balsam, but at the best it will cut a sorry figure on the screen.—W. J. Lancaster.

[illegible]—**Lantern Reading.**—It is easily done if you have a friend who is a photographer. Get him to take a photograph of your bill on a glass plate of such a size as will suit your lantern. This will be a negative; that is, the letters will be white on a black ground. If you don't object to that, then you can use this negative in your lantern. If you would prefer the lettering black on white ground, get your friend to print through this negative on to another glass plate, and the result will give you a picture for your lantern of the natural black letters on white ground, which I have supposed your bill to be.—Velvex.

[517[illegible].]—**Water Motors.**—Probably owing to to the pipe being throttled somewhere before it gets to the hose—perhaps at the tap, or connection with main.—Kanet.

[51719.]—**Water Motor.**—If the querist examines this, he will find that less water issues from his pipe when by contracting the opening he gets a force producing a jet 10 or 12ft. high. With the open end there is little or no pressure on the issuing water. The reason of all this is that no more water can flow than the supply permits. Now if the water has to flow through a long and small pipe, the pressure in the main is exhausted in driving it through, and if the opening at the end is of the full bore, the water simply runs out. If the opening is reduced so as not to allow free flow, a corresponding amount of pressure can be set up, which produces a jet.—Sigma.

[51721.]—**Sore Leg.**—For years I had two of the worst of bad legs. The following is my experience and cure. Rest, and keep the leg clean. Don't go to a doctor too much—he will charge you £10 for telling you to rest; don't drink beer, but a little whisky; and get twopennyworth of Goulard's extract, not diluted; put it in one quart of rain or soft water, it will then have the appearance of milk; wet linen cloths, and apply to the wound, to be changed as often as become warm or dry; when walking, or at work, put three or four thicknesses of linen on, and over this a bit of oiled silk and bandage, comfortably tight, and change at meal times if possible. The above will be, I hope, some use to J. Dexter, as it has cured bad legs of as long as twenty years' standing.—A Country Chip.

[51722.]—**Prevention of Rust in Firearms.**—Rangoon oil is the best for preserving the interior of rifles, &c., from rust. It does not lie on the surface of the metal only, but sinks in.—R. B. Hedley.

[51722.]—**Preventing Rust in Firearms.**—Fill with fresh lard *free from salt and moisture.* I have some now that were filled three years ago, and all right, although my house is rather damp. N.B. Make your own lard.—Kanet.

[51722.]—**Rust in Firearms.**—The best plan is to leave the barrel alone after firing, and the fouling will act as a protection against rust. It is, of course, necessary to take a "blow-off" shot before commencing to practice again. The lock may be cleaned with a little sweet-oil. I used to spend much time in cleaning my rifle after each evening's practice, but find the above method quite satisfactory, and much less trouble.—Wm. John Grey, Elswick Science School, Hon. Sec. Newcastle Rifle Association.

[51724.]—**Height of Barometer.**—·2618 must be added to the reading of "Norfolk's" aneroid. He must also allow for variation of temperature; but for all practical purposes $\frac{26}{100}$ will be near enough.—F. W.

[51724.]—**Height of Barometer.**—Supposing the height of the barometer in London is 30·00, reduced to mean sea level, and the thermometer attached to the barometer 60°, then if the thermometer on your aneroid stood at 60°, the finger on the dial should read 29·76.—M.M.I.Sc.S.

[51724.]—**Height of Barometer.**—From the following table you can easily reckon the difference—counting "0" as London:—

Feet 500	....	30·55 inches.
" 400	....	30·41 "
" 300	....	30·33 "
" 200	....	30·22 "
" 100	....	30·11 "
" 0	....	30·00 "

—Chemicus.

[51725.]—**Printing Potato Sacks.**—"Spuds" must either stencil or get the name and trade mark printed on with type or block at a jobbing printer's. Few care about the job, as it is a very dirty one.—Eccentric.

[51725.]—**Printing Potato Sacks.**—A very good way would be to have various alphabets made of plates of wood, made of nearly exact thickness and size, so that a number slipped or slid into a frame, would form the various words required; but instead of the letters being engraved on the wood plates, let them be bored through the wood as for brushes, and let bristles be drawn into the holes, in fact, let the hairs form the letters A B C, &c., &c. Having, by the single letters, brought together in the frame formed your wood, dip the frame face downwards in a trough containing the ink or paint, dab or press frame on the sack, and printing is done. If the trough is partly filled with coir fibre dust, and cloth spread evenly over it, the stamps would not take up too much ink or paint.—Hoinos.

[51729.]—**Electric Engine.**—Siemens' armature is not self-starting; it has a dead point. It can, however, be made to stop ready for starting by a catch in a disc fixed on the axis. A ring motor was described some time back which is self-starting, and will very likely suit you.—J. Sutcliffe.

[51735.]—**Boat.**—I cannot give sectional drawings; but if of service, shall be happy to give you measurements of 13ft. × 4ft. 6in. c.f., if you will specify what you require.—R. Hansen.

[51735.]—**Boat.**—If "Sir W. Waller" has the drawings of boat he wishes to build, drawn 1½in. to the foot, let him get a pantograph, and set it to enlarge 8 to 1, and the result will be a full-size drawing.—A Country Chip.

[51736.]—**Mechanics.**—I do not think the amplitude of vibration can be calculated from the data given. With regard to second question we have the well-known formula:—

$$f = \pi\sqrt{\frac{l}{g}}$$

$$f^2 = \frac{\pi^2 l}{g} \therefore l = \frac{f^2 g}{\pi^2}$$

using the approximate value $\frac{22}{7}$ for π, we get

$$l = \frac{2{\cdot}25 \times 32}{\left(\frac{22}{7}\right)^2} = \frac{2{\cdot}25 \times 32 \cdot 49}{484} = 7{\cdot}3\text{ft.}$$

—Wm. John Grey, Elswick Science School.

[51740.]—**Pills.**—To coat with sugar, you will require two or three soup plates and a covered earthenware pot. There are three operations:—

1. To moisten the pills.
2. To cover with chalk and sugar.
3. To finish by polishing.

To moisten the pills. Pour a good quantity of mucilage of tragacanth (made by dissolving 4gr. gum tragacanth in 1oz. of water) into one of the soup plates; turn it about so as to well cover the surface; drain, then introduce the pills, and shake about. Covering with chalk and sugar:—**Have a plate ready, with equal parts of French chalk and powdered loaf sugar spread over it, shoot the wet pills into it, and shake with a circular motion until fairly covered. Then put them into the pot, and shake with a jerking motion. Polishing. A jujube** tin answers very well for polishing. Sift the loose powder from the pills, and transfer to the tin, and shake briskly till dry. To silver, take a covered jar, same as used for coating with sugar, fill with mucilage, drain, and place pills in it, shake with a circular motion until pills are covered; then place with the pills some silver leaf (sold in books), and shake till covered.—CHEMICUS.

[51741.]—**Fixing Pipes to Harmonium.**—I should not advise "Chemicus" to apply pipes to his Alexandre harmonium, under the conditions he names. The varying pressure of air, proceeding from the ordinary pressure bellows, would cause the pipes to fluctuate in their pitch and tone, and for this reason the pipes would not always be in unison with the reeds. If the querist wishes to know how certain pipes are tuned, I will furnish the necessary information with pleasure; but I cannot, as a friend, recommend him to carry out such an idea as he proposes. I have had no experience with paper pipes, although I have heard that if they are properly made they produce a very clear and distinct kind of tone. Could not "Uranium" inform us how paper pipes are made? I think this information will be useful and interesting to a great number of our musical readers.—G. FRYER.

[51749.]—**Motor.**—The steel flanges will neutralise the magnetism in the armature; you had better replace them with brass ones.—J. SUTCLIFFE.

[51754.]—**Agriculture.**—As I happen to be a farmer, can answer "Estate Agent's" query, on a subject which probably the majority of our readers know nothing about. Appended is table:—

	Aver. val.		Aver. weight per acre.
	£	s.	Tons.
Mangolds	20	0	30 to 35
	6	0	
Turnips ..	4	10	20 to 25
Swedes	15	0	
	5	0	15 to 30
Carrots ..			10 to 15

The two values are for consuming price—i.e., roots eaten on ground, the other where they are drawn entirely off farm. The above figures must not be taken as correct, as no crop varies so much as the root crop in quality and value. Carrots are valued according as they are grown for stock or for garden stuff.—DERWOOD.

[51756.]—**Martini Henry Cartridges.**—These contain 85 grains of powder. I do not know what particular sort is used.—WM. JOHN GREY, Elswick Science School.

[51756.]—**Cartridges for Martini-Henry Rifle.**—I cannot tell T. H. Hall the name or maker of the powder used in the Government factory. In match shooting riflemen prefer to fill their own cases, especially if for use on long ranges, and invariably use Curtis and Harvey's A. W., or their No. 5 or 6, being the most reliable and suitable for rifle work. T. H. H. will require solid drawn brass shells, lubricating wads, a box of caps and bullets properly papered, ·450 gauge, 85 grains powder, weighed to a grain, a variation of even half a grain at the long ranges tells sensibly upon the work. The material mentioned may be obtained at any of the Birmingham houses in this trade, or from John Rigby, Dublin.—ECCENTRIC.

[51757.]—**Bradford's Washing Machinery.**—How *can* anyone answer "One in a Fix"? Why does he not write to the makers, who are the best of their kind? People buy second-hand machines and then declare they are useless, when it is their own stupidity and niggardliness that are in fault. In my experience no other maker's machines equal Bradford's, either for speed, cleanliness, or efficiency.—WASHERMAN.

[51759.]—**Escapements.**—To "R. E. B."—I cannot give you any reason why oil should not be applied to verge pallets, other than that oil would hold dirt and cause cutting. As regards the lever escapement, oil should not be applied unless you wish the fork and pin to cut and the watch to go badly. I have replied to "oiling watches," page 394, June 29.—R. E. B.

[51762.]—**Motor for Dynamo.**—Your dynamo can be worked direct by a quarter-horse turbine, but the cistern of 4ft. 2in. by 3ft. 3in. by 2ft. 8in. is too small to be of any use; it would not work it for five minutes. If you have not a large supply of water, get a small steam-engine and a half horse-power boiler.—J. SUTCLIFFE.

[51762.]—**Motor for Dynamo.**—If you regard the power of two men as equal to ¼ h.p., then as you have only a fall of 25ft., or a pressure of about 12lb. on square inch, for this pressure, to develop a power equal to that of two men, you would want a motor with cylinder 4in. diameter, and supply pipe 2¼in. diameter, the cost of which would be from £20 to £25. In your case I should recommend a gas or hot-air engine, as being less expensive in working.—DERWOOD.

[51765.]—**L. and N.W. Locos.**—In my last week's query, for "numbered 2527," read "numbered *above* 2527."—TITTESWORTH.

[51766.]—**Average Pressure.**—Multiply the weight by the distance through which it moves in feet, and divide by the area of piston, multiplied by feet traversed by piston per minute, and the product will give the average pressure necessary. Now, circumference of a pulley $1\frac{7}{8}$in. diameter $= 5\cdot89$in.; hence $(5\cdot89 \times 100) / 12 = 49$ft. $\times$ 5lb. $= 245$ ft.-lb. Then the traverse of piston $= (1\cdot875 \times 2 \times 100) / 12 = 31\cdot25$ft. $\times$ $1\cdot227$ area $= 38\cdot34375$; therefore, $245 / 38\cdot34375 = 6\frac{4}{16}$lb. per sq. in., the average pressure required. Now, as the radius of the crank is equal to the radius of the pulley, it follows that the weight divided by area of piston must give the pressure necessary to balance such weight: hence, 5lb. $/ 1\cdot227 = 4$lb. per sq. in., the required pressure.—ENGINEER, Dewsbury.

[51770.]—**Razor Paste.**—Mix equal parts of jeweller's rouge, blacklead, and suet.—THE KENT HERMIT.

[51770.]—**Razor Paste.**—Take a piece of coke and pound it very fine in a mortar, and then mix with sweet oil till it gets to a paste.—A. AND E.

[51774.]—**Mechanical Pianoforte.**—For the sake of brilliancy in the treble notes, I should have four strings, say $\frac{3}{16}$in. apart. Do not have the hammers wider than required, and cover them with rather hard felt. You can have two covered bass strings to each of the lower notes, which must vary in gauge accordingly. If a sketch is of any use to you, I will furnish an excellent plan, providing the Editor can spare the little amount of space necessary to describe it.—G. FRYER.

[51775.]—**Leclanche Battery.**—The ammonia is the product of the action, and as the battery is not meant for heavy work, there ought to be only a very faint smell. It is about the worst and most expensive battery one could use for electro-plating. The Smee is the best for inexperienced persons or for occasional use. The Daniell is best if there is any use for the reduced copper, or if it can be employed in the form of an electrotyping apparatus so as to produce objects as well as do the electrical work.—SIGMA.

[51775.]—**Leclanche Battery.**—"The smell of ammonia" referred to by this querist simply indicates that the battery is performing its functions. The zinc is attacked, dissolves, and forms a double chloride of zinc. The free ammonium (NH_4) is oxidised by the peroxide of manganese, and ammonia and water are formed. The binoxide is converted into the lower or sesquioxide Mn_2O_3. Before contact—

$$Zn,\ 2\,(NH_4Cl),\quad | \quad 2(MnO_2),\ C.$$

After contact—

$$ZnCl_2,\ 2NH_3,\ H_2O,\quad | \quad \overline{Mn_2O3,}\ C.$$

For simple electroplating the Daniell battery is decidedly superior to the Smee.—WALTER H. COLLINS.

[51776.]—**Electric Bells.**—Connect each of your pushes with the carbon pole of your battery, and also to the left-hand binding-screw of each of your bells; connect the right-hand screw of each bell to the zinc pole of your battery; then, if your bells are good ones, and your battery is good also, you will ring the five bells simultaneously by pressing either of the pushes. By regarding the thief alarm contact as an additional push, and connecting it with the system in the manner above described, it will act in the same way, and if you insert the switch in either of the wires proceeding from it at any point before reaching their junction with the main circuit, you will be able to "cut out" the alarm without interfering with anything else.—R. T. LEWIS.

[51778.]—**Steam Flour Mills.**—It depends a great deal on the size of stones and way in which they are dressed, and the quality of grain ground. A pair of 3ft. 9in., as I have now in use grinding barley into coarse flour, takes about 4½ h.p. to grind about 12qrs. in 10½ hours.—DERWOOD.

[51779.]—**Metallic Precipitates.**—This is rather a confusing question. Does querist want to know something which will precipitate all the metals, or different chemicals to precipitate each metal? Bronze is composed of copper, zinc, tin, and lead. Solution of hydric sulphide (sulphuretted hydrogen) would precipitate lead, copper, and tin: ammonium sulphide, hydrate, or carbonate, precipitates a solution of a zinc salt as sulphide, hydrate, or carbonate respectively. Ammonium carbonate, added to a solution of all these metals, would precipitate every one of them; so that if "An Experimenter" simply wishes to precipitate all the metals, and does not care what the resulting compounds are, this would be the easiest way.—R. A. R. BENNETT.

[41781.]—**Bichromate Battery Chemistry.**—The ruby crystals are chrome alum produced by the action. The greenish ones are, I think, only formed when the battery has been worked to exhaustion, or when much hydrogen has been given off. They are protosulphate of chromium, I think, but probably in combination with zinc sulphate. The others are zinc sulphate.—SIGMA.

[51781.]—**Chemical.**—The ruby-coloured crystals are those of chrome alum (K_2CrO_4, CrO_3); what the green ones may be I don't know at all. There is nothing in the ordinary bichromate solution which would form green crystals, unless it was sulphate of chromium, and it is scarcely likely to be that; probably impure sulphate of zinc. Dissolve some of the ruby crystals, and heat the solution to boiling; if it turns green, they are certainly crystals of chrome alum.—R. A. R. BENNETT.

[51782.]—**To Violinists.**—Proficiency in staccato bowing is the result of long patient study. It should be practised very slowly at first, and it is of the utmost importance that the bow does not leave the string during the playing of the whole passage. The notes are, as it were, cut out of the string by a sharp jerk of the bow, and the vibration of the string is immediately stopped by pressing the bow down. There is a bastard kind of staccato which is produced by the elasticity of the bow, which bounds from the string between each note. To produce a clear, pearly staccato, the bow must be a good one, neither too weak nor too strong. It must be light and elastic, but stiff withal. Such bows are valuable, and when found should be cherished. I advise your correspondent to procure a bow made by a good maker, for which he will have to pay something over a guinea. If he cannot then play staccato music, the fault lies not in the bow but in him who boweth.—THOS. LISLE.

[51784.]—**Electric Tricycle.**—This is a very interesting subject. I suppose the chief practical impediment to the attainment of this object in an independent machine is the weight of the accumulator, and the impossibility of generating by any known battery a force sufficient for reasonable propulsion. We cannot create force, but must derive it from some source. Could not the force of the human body be utilised to turn something which might set an electro-magnet revolving, and so develop a current of the requisite amount of power? I write as a tyro, and under all due correction.—W. B. M.

[51784.]—**Electric Tricycle.**—I fancy "Apprentice" will have a great lot of bother in trying to make his tricycle run by means of electromotive power, even if he follows the method adopted by Messrs. Ayrton and Perry. I don't know anything about the copper oxide battery; it probably does not give so much E.M.F. as the single fluid bichromate, and I base my calculations from all use of this. The "Griscom" motor of the size now sold would not be of the slightest use. This little motor (according to prospectus now before me) gives with 6 gallon bichromate cells 1,000ft.-pounds, and as a force equal to 5,000ft.-pounds would be required to move a tricycle on the level, 30 of these cells would require to give power wanted (this is only approximate); in theory, not so many would be wanted. The cells would have to be sealed to prevent solution spilling, and the weight of these batteries (30) being something like 3cwt. in addition to weight of rider and machine itself, I think "Apprentice" will see that as yet the propulsion of tricycles by means of electricity (derived from batteries) is not practicable, at least, that is the impression of—DERWOOD.

[51785.]—**Electric Telltales.**—If "E. C." will send for J. T. Gent and Co.'s (of Leicester) book on "Electric Bells" I think he will get the required information.—H. G. E.

[51785.]—**Electric Tell-Tales.**—A most ingenious system is Hancock and Yeates' patent electric tell-tale clock, which I saw working for a time at the Mountjoy Female Convict Prison, Dublin, and I believe gave satisfaction. The watchman has to touch a press-button fixed in each room or place at certain times, which is recorded on a drum attached to the clock, which can be placed in the master's room any distance away. If the button is not pressed at the right time, an alarm rings; or if the wires are cut, or the button plugged in, the alarm will also ring. In fact, the only way to keep the alarm from sounding is for the watchman to press the button at the right time, and in a certain order, which can be altered for different places in the electrical gear in the clock part. Any number of stations may be put on in this system. Each station, when the button is pressed, is recorded on the drum at the exact time of pressing, so in the morning a complete record of where the watchman has been during the night can be seen. I don't know what the cost of the whole apparatus is. The patent is "Hancock and Yeates' Watchman's Electric Tell-tale and Fire-Alarm, No. 1,598, April 24, 1877." Messrs. Frengley Bros., Crow-street, Dublin, have bought the patent, and, I believe, supply the clocks. If "E. C." would write to them I am sure he could get full particulars of cost, &c.—IOLANTHE.

[51786.]—**Water-Way.**—The lowering of the head end. They were quite transparent, and one could see easily, with a 1½in. objective, the heart's (?) action on a long irregular-shaped mass of red fluid. They were exceedingly lively, and seemed to have shed their skins—as there were traces about of their membrane resembling the contour of the animals. There was also present the dead and flattened body of a species of small spider about 1-25in. diam.; but this might have been an accidental spider egg introduced to the box at the same time as the other eggs.—P. WARD.

[51829.]—**Chimney.**—I have a house three stories high: rooms about 6 or 7ft. The under room has a chimney to it. I want to put one to the next room. Can I carry it into the under one, so as not to interfere with the draught? Will some kind brother tell me the best way? This is to be a kitchen. I should therefore be glad of size of fireplace and chimney for small cottage oven grate, and the best sort of the latter.—CHIMNEY.

[51830.]—**Photographic.**—I am terribly bothered in trying to get effectually rid of our friend "hypo.," both in washing my negatives and prints, water being a very scarce commodity with me, as all the water I use for photographic purposes has to be fetched in buckets a distance of about 100 yards, and then siphoned out of a bucket which acts as a cistern for washing negatives, &c. Can "A. T. P.," or any of "ours," give me the benefit of their experience, and assist me in this matter? The labour is indeed very great, and if it were not that I take a great interest in the seductive art, I should have given it up before this. Are there any means of getting rid of hyposulphite of soda without a copious use of water, and without damaging the negative or print? A word or two on this subject will be gratefully received.—AMATEUR TYRO.

[51831.]—**Electric Gas Lighter.**—Can any reader of ours inform me of the constituent parts and action of the battery of this apparatus? Also how to recharge when necessary without sending to the makers.—VANDU.

[51832.]—**Damp Shop.**—I have a shop which, when I open in the morning, has a very bad smell, caused by dampness. The landlord has done all that I can get him to do, but has not improved it much. As I am obliged to be in the shop nearly all day, I wish to know what I could use to keep the sickening odour away, which is very objectionable to customers on first entering. I am sitting nearly all day, so cannot always have the door open, except it is very warm. Any suggestions would oblige.—SHOPKEEPER.

[51833.]—**Draught Screen for Drawing-Room.**—Wanted instructions how to cover with canvas and paper, and to prepare the surface for glueing or pasting on pictures.—NEMO.

[51834.]—**Soap and Soda.**—Given a mixture of soap and soda in powder. Can any fellow reader state a simple method of estimating the quantities of each?—A. SMITH.

[51835.]—**Contact Breaker.**—Will some of our electrical friends kindly suggest a plan for contract breaker that will answer following requirements? Have made a model to work by electro-magnet and armature, and it works well when I make and break contact myself. The armature is arranged as in an electric bell and retains its normal position by its own weight, drawing some levers to work the model; but if the breaker is made as an electric bell the armature works too rapidly, and I want one that will work slowly, pulling the armature about from ¼ to ½in. How may it be accomplished?—KIKO.

[51836.]—**Alkaloid of Iron.**—Perhaps some of your readers can inform me of an inexpensive process by which I can make small quantities of an aqueous solution of iron or iron and sodium, or the name of a textbook in which the process is detailed, as it is not given in the one I have?—J. McINTOSH.

[51837.]—**Compressed and Liquefied Gases.**—Can any subscriber give me answers to the following queries? Any information will be thankfully received. Whether atmospheric air can be liquefied, and if not, to what extent compressed. Please state the gases that can be liquefied and those that can only be compressed. I should also feel obliged if any one could inform me whether there is a book published on the subject and where it can be obtained. I am aware most books on chemistry treat on the subject.—R. W.

[51838.]—**Size of Flywheel, &c.**—Would some of our readers kindly me what is the rule for the size of flywheel with regard to size of cylinder? I have two cylinders, each 1½in. bore and 4in. stroke, and intend working them at, say, 10lb. pressure. What weight and what diameter of flywheel should I have?—G.

[51839.]—**Chemical.**—What is the best process for finding the exact percentage of morphia in opium? A prompt and detailed answer will much oblige.—L. B.

[51840.]—**Nickel Plating.**—Will any of your readers inform me why, during the above process, the article being plated is sometimes covered with cloudy spots or smears presenting a mottled appearance and which easily wipes or brushes off, exposing the metal underneath. The salts I use have been in use for about 9 months with additions now and then. Sometimes the articles come out nice and bright with the the nickel firmly adhering. At other times it comes as above. Are the salts deteriorated by use? If two batteries are used for greater power, should the corresponding wires from both batteries be attached to the respective rods over the vat by the same connection? I use a vat with 10 or 12 gallons of salts, and what is known as an American battery, sometimes two.—ALPHA.

[51841.]—**To Mr. Wetherfield.**—A brother of mine died nine years back at the Cape of Good Hope. I want to find out whether or not he made a will. I know no one there who can or will give me the information. Can you put me in the way to find out, and if he made a will, how shall I get a copy of it? If no will has been proved, and no one has administered to property he possessed, what would you advise me to do? I am his eldest brother. My brother was a widower, and had no children when he died. He was possessed of leasehold houses in London (England). No will of his has been proved at Somerset House, and letters of administration have not been granted. Can I now administer to his estate in London?—A BAFFLED ONE.

[51842.]—**Colouring Wax Dolls.**—Will some one inform me how wax dolls may be recoloured? They have been somewhat exposed to the sun, and have become very pale.—T. W. P.

[51843.]—**American Railways.**—Can any reader give a short statement of the mileage and routes of the principal American Railways, with a few particulars as to their financial position? I see the completion of the Northern Pacific has been followed almost immediately by a rapid fall in the price of its shares. Why is it that American railway shares fluctuate so? I have noticed recently that several descriptions have receded as much as 50dol. in a few months. Denver and Rio Grande shares, for instance. Is this line a new one, and are the fluctuations in its shares merely stock exchange fluctuations, or has it gone to the bad in such a decided way as to cause the decline?—S. J.

[51844.]—**Transmitter.**—Would any correspondent kindly tell me the form of transmitter used by the telephone company in Coleman-street, and how the connections are made for transmitter, coil, bell, and telephone? Is there any recent book fully illustrated?—C. L.

[51845.]—**Photographic Studio.**—Would some reader kindly instruct me in this? I am thinking of building a studio something like the following: 20ft. long, 10ft. wide, 7ft. high in the square, pitched roof, one side 4ft., sash 16ft. long, facing north. How and where should I have the top light? I thought about 6ft. light in the centre, side facing north; but I am afraid the light would fall all on one side of sitter. Please give me plain instructions, and oblige.—M. R.

[51846.]—**Hyposulphite of Soda.**—After fixing a batch of prints, I have thrown above away—3oz. to one pint. Would same do for clearing dry plates after developing?—M. R.

[51847.]—**Small Dynamo.**—Would one of these that will light a couple of lamps do to drive an induction coil that gives a good thick inch spark?—M. R.

[51848.]—**Lost Watch Wheel.**—To "ALFOJOR."—Will you please give the method to determine the number of teeth and leaves in a wheel and pinion—say fourth wheel—which has to be replaced by a new one?—HALL.

[51849.]—**Commutator.**—Would "Sigma" please say how I can arrange the commutator of a Siemens' armature so as to get a positive and a negative current always in the same direction, same as from a Gramme machine, and oblige?—WIRE.

[51850.]—**Canoe, or Small Sail Boat.**—To "BAIL OUT."—Having been told of a plan to get rid of water, either leakage or that taken over the side, I write to know if any of "ours" know of its practical working—viz., to have a pipe projecting through bottom of boat with end bent towards the stern of boat, and that when an inside plug is withdrawn (or a tap turned) whilst the boat is travelling at a good speed, that the water will be run out of the boat by the suction of the passing water. Information will much oblige; for if this plan will act, it would suit my case admirably. Speed attainable up to nine miles an hour. Both pump and bailing, now in use, are troublesome and tedious—especially when under way.—CÆSAR.

[51851.]—**Chemical.**—Will some kind reader tell me if the following mixture is chemically combined?—9 parts $KClO_3$, 2 parts $C_{12}H_{11}O_{11}$, 1 part $K_4FeC_6N_6$, with C52·9H7·0N17·1O22·9. Also if there is any danger in compressing the mixture by hydraulic pressure?—NOVICE.

[51852.]—**Gazogenes.**—Will any reader kindly explain the construction of the metal heads of these aërated-water machines, and state whether they can be taken to pieces for repair? I have had mine two or three years, and it is by the best makers (Gerault and Co.), but for some time past, whenever it is charged, there is an escape of air, which renders the water quite flat. Thinking it might be at the junction with the glass, I carefully cemented it; but the escape still continues, and is evidently inside the head. It has been to the maker's once, but without success, and their repairs are somewhat costly?—BETA.

[51853.]—**Electric Lighting.**—What advantage is gained by joining incandescent lights in series of equal numbers? I can see a slight saving of wire in running the circuits; but apart from this I fail to see any gain—unless it is lowering the resistance of the circuit, which I don't quite see. And why should series have to be equal in number of lamps, when they are actually all on the same circuit, as only two wires lead from dynamo? This question has puzzled a good many like myself. Will any electrical reader kindly give the desired information in as clear a manner as possible.—VEBER.

[51854.]—**Legal.**—Would Mr. Wetherfield answer the following?—I sold my business some time ago, and I signed a covenant to this effect (Extracts from deed):—"Will not, during the continuance of the said term of 21 years, carry on or be engaged in the trade or business of a hot-water engineer, gasfitter, &c." The question is this: I have invented several things. One thing is an apparatus for heating offices, &c." I want to know whether the party that bought my concern can prevent me from manufacturing them for wholesale or otherwise. I am now living about 310 yards from the business that I sold.—ONE IN A FOG.

[51855.]—**Telescopic.**—I have a small terrestrial telescope by Dolland. Could it be used for observing sunspots, &c.? If so, how could I darken it, &c., for that purpose?—WARRAGUL.

[51856.]—**Ozone Papers.**—Kindly inform me how to make ozone paper to purify the atmosphere of a room after dinner, and at other times. Also what kind of bibulous paper is best suited for the purpose?—H. GEORGE.

[51857.]—**Mushroom Bed.**—Will any one please to tell me a way to grow mushrooms artificially, and the right time of the year to plant the spawn?—G. T. DENYER.

[51858.]—**L. & S.W.R. Locomotives.**—Would "W. B. P." kindly favour me with the dimensions of bogie engine, No. 136?—F. W. BREWER.

[51859.]—**Fairy Bells.**—Will Mr. G. Fryer or any reader kindly inform me how to make, with dimensions of same?—J. W. L.

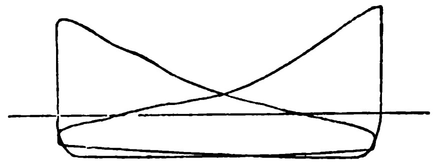
[51860.]—**Roller versus Stone Milling.**—Can any of ours kindly give me their experience of the above, or suggest any improvement on my present mode. I am now operating five pairs of stones on the half-high grinding system, making about fifty per cent. middlings, but cleaning my brass with the burrs. The middlings are graded into two series, purified and rolled separately. I take off about 10 per cent. of patent, which is very good indeed, but my customers are asking for a much larger supply of this than I can at present make. I now propose to increase my make of patent flour by putting in the best form of first break machine I can procure, aspirating the product, and scalping to take out the crease dirt. Then, by a second reduction on stone grinding, very high, make my middlings. Scalp these to take out germ and the coarsest middlings, these and the bran going to separate rolls, the remainder of the chop to a dusting reel. The middlings from this would be graded and purified, the coarsest going to rolls, the finest to stones. Some of ours may be working on this system, and can inform me what quantity of patent I could safely take off, and whether it would be of equal quality to that I now take from my rolls. I have seen some splendid work on the first break done by disc mills, and am led to think that the superiority of this over the first break by rollers will place my manufacture on a level with an entire gradual reduction system, for which I have not room.—DUSTY.

[51861.]—**Earth's Path about Moon.**—Would "F.R.A.S." kindly say the exact distances of the earth and the moon from common centre of revolution of their orbits about each other?—P.

[51862.]—**Radiant Heat into Light.**—Is there any known instance of radiant heat being converted into or affording light when no combustion in the ordinary sense takes place?—P.

[51863.]—**Arranging Brass Band Music.**—I wish to arrange some glees, anthems, and four-part songs for a brass band of 24 performers. Would any of our musical friends kindly inform me which are the most suitable instruments for the particular vocal parts? Any hints on the subject would oblige.—EUPHONIUM.

[51864.]—**Indicator Diagrams.**—The following diagrams are taken from a horizontal condensing engine. Cylinder, 30¼in. diam.; 4ft. stroke, running at 40 revs. per minute. Boiler pressure, 40lbs. Vacuum according to guage glass on condenser, 12¾lb. Scale of diagrams, 24lb. to one inch. The slide has iron cut-off valves set at time of indicating to cut off at ⅜ stroke. The main valve has ¼in. lead and 1in. outside lap. How can I set these valves to get nearer boiler pressure (there being only about 15ft. of 6in. steam pipe between engine and boiler), and more vacuum? Foot and head valves and air-pump bucket in good order.—P.A.D.



[51865.]—**Scientific Lending Library.**—Is there any place where scientific books can be had at a moderate subscription? If not, would it not pay well to get one up; or is there any place where they can be read besides the British Museum?—F. W.

[51866.]—**Dark Slide.**—When Mr. Lancaster gives this much-desired information, will he also give an opinion on, and instruction for making, the changing box, lately described in No 961. of the "E.M." Would it not be useful if it only contained seven instead of thirteen plates? It would not be such a heavy back weight on the camera.—F. W.

[51867.]—**Bicycle Wheel.**—Would any of our readers kindly inform me the best way to centre a new wheel? Also the best way to put on rubber tires?—J. H. H.

[51868.]—**Telescope.**—To MR. LANCASTER AND OTHERS.—I have in my possession an achromatic telescope for terrestrial purposes, with a 2¼in. object-glass, and 46in. focal length, warranted best make, by A. Franks, Manchester. Could you inform me what amount of magnifying power I might expect of it at present, and what is the highest possible power of an astronomical eyepiece that could be adjusted to its present make, and also its cost?—ASTRO.

[51869.]—**Ozone.**—I should be glad if you, or some of your readers, could give the generally accepted theory of formation of ozone when a stick of phosphorus is placed in a jar of moist air (Roscoe "Elem. Chem.," page 15). If someone would kindly give results of any investigations which have been made on the subject, I should be greatly obliged.—OZONE.

[51870.]—**Poor Law.**—To MR. WETHERFIELD.—Will he oblige by answering the following?—A man and his wife and two children—one aged nine, the other 16—had to part; she goes into the union. He is summoned before a magistrate, and an order made on him for 12s. per week for her support and the children. She now has come into property. Is the man now bound to pay her 12s. per week still, or can the guardians force him, if she goes into the union, she not now being destitute?—LAW.

[51871.]—**Keel for Model.**—Can any correspondent inform me as to the best way of casting lead keel on to the false keel of a working 2ft. 6in. model of a yawl? I have seen them on the boats, and you are unable to see any heads of screws through the bottom of keel.—MODEL SAILOR.

[illegible]

[illegible] with a [illegible] water displaced [illegible] filling it [illegible] marking *this* [illegible] commencing from [illegible] 22 is the specific [illegible] "Deschanel," p. 86. [illegible] the box *a* filled with [illegible] marks the point of its displacement [illegible] this is the specific gravity [illegible] space between these two last [illegible] course, to be graduated 2·4 "degrees," [illegible] this will give the dimensions of the [illegible] the rest of the tube upwards. The [illegible] the box *a* is determined by the con[illegible] to the maker of the point 22. If he [illegible] 22 to be *very* low down on the tube, *a* must be a long box, and *vice versâ*. Of course, if [illegible] necessary, the box can be withdrawn by a silk thread attached to the top.

[illegible] may be objected that this method does not [illegible] actual displacement of water, inasmuch as the substance does not take the place of the water—i.e., is not actually immersed in it; but that does not matter to the operator, as long as the correctness of his scale of specific weights is [illegible] (as it, of course, will be here) by two [illegible] pure substances—Platinum and Gold—and the displacement points of these two ought

Fig. 1 Fig. 2.

(Scale, 1·5in. to the foot.)

a, a small brass box filled with the fine sand of the substance the specific gravity of which is to be determined. The outer diameter of this box must be as near as possible to the inner diameter of the tube *b*, but the box must pass down the latter without obstruction.

b, a brass or copper tube, supposed to require to be about 3ft. long, down which, standing perpendicularly, the box *a* filled with the mineral sand, is to be dropped.

c, a little oil covered by a pasteboard or wooden disc or wad, to receive the first impact of the sand-laden box *a*.

d, a strong U-bent glass tube, filled with rain or distilled water, covered in its left leg with oil (*c*), and graduated outside its right leg with a scale (determined by the box *a*, full of platinum filings or sand), showing the amount of water displaced by the fall of the box (*a*). The right leg is covered by the slightly bent tube to prevent any water spirting up and dropping back into the tube.

The left leg of the tube may be graduated at *c* in order to measure the first violence or energy of impact.

not to be marked except as the result of many careful experiments.

At all events, such an instrument as the above described may surely claim at least equal correctness with the method detailed by Professor Cornwall, "Determinative Mineralogy," 1882, page 252, Fig. 69, in which, apparently, an ordinary butcher's spring "scales" is used (!) in which the list of degrees is "engraved on a mirror, so that the index and its reflected image to light during the systematic investigation, as reported on by Dr. Falconer, of the Brixham Cave, must, I think, have prepared you to admit that scepticism in regard to the cave evidence in favour of the antiquity of man had previously been stretched to an extreme (*Report. Brit. Assoc. 1858, Trans. Sect., p. 95*).

It is probably unnecessary to quote further to show how very large a share the exploration at Brixham had in impressing the scientific world generally with the value and importance of the geological evidence of man's antiquity. That impression, begun as we have seen in 1858, has not only lasted to the present day, but has probably not yet culminated.

Few, it may be presumed, can now doubt that those who before 1858 believed that our fathers had under-estimated human antiquity, and fought for their belief, have at length obtained a victory. Nevertheless, every anthropologist has doubtless from time to time

"Heard the distant and random gun
That the foe was sullenly firing."

The "foe," to speak metaphorically, seems to consist of very irregular forces, occasionally unfair, but never dangerous, sometimes very amusing, and frequently but badly armed or without any real armour. The Spartan law which fined a citizen heavily for going into battle unarmed was probably a very wise one.

For example, and dropping a metaphor, a pamphlet published in 1877 contains the following passage:—"With regard to all these supposed flint implements and spear and arrow heads found in various places, it may be well to mention here the frank confession of Dr Carpenter. He has told us from the presidential chair of the Royal Academy that, 'No logical proof can be adduced that the peculiar shape of these flints were given them by human hands.'" The words ascribed to Dr. Carpenter are put within inverted commas, and are the whole of the quotation from him. I was a good deal mystified on first reading them, for while it seemed likely that the president spoken of was the well known member of this Association—Dr. W. B. Carpenter—it was difficult to account for his being in the presidential chair of the Royal Academy, and not easy to understand what the Royal Academy had to do with flint implements. A little search, however, showed that the address which Dr. W. B. Carpenter delivered in 1872 from the presidential chair of, not the Royal Academy, but the British Association, contained the actual words quoted, followed immediately by others which the author of the pamphlet found it inconvenient to include in his quotation. Dr. Carpenter, speaking of "common sense," referred by way of illustration, to the "flint implements," of the Abbeville and Amiens gravel beds, and remarked, "No logical proof can be adduced that the peculiar shapes of these flints were given to them by human hands; but does any unprejudiced person now doubt it?" (*Report Brit. Assoc.* 1872, p lxxv.). Dr. Carpenter, after some further remarks on the "flint implements" concluded his paragraph respecting them with the following words: "Thus what was in the first instance a matter of discussion, has now become one of those 'self-evident' propositions which claim the unhesitating assent of all whose opinion on the subject is entitled to the least weight."

It cannot be doubted that, taken in its entirety, that is to say, taken as every lover of truth and fairness should and would take it, Dr. Carpenter's paragraph would produce on the mind of the reader a very different effect to that likely, and no doubt intended, to be produced by the mutilated version of it given in the pamphlet.

A second edition of the pamphlet has been given to the world. Dr. Carpenter is still in the presidential chair of the Royal Academy, and the quotation from his address is as conveniently short as before.

It would be as easy to bring together a large number of similar modes of "defending the cause of truth"—to use the words of the pamphlet just quoted—but space and time forbid.

Mr. Pengelly did, however, give some other instances of extraordinary perversions of fact, and then proceeded with his history. As already intimated, the result of the researches at Brixham quickened a desire to re-examine the Kent's Cavern evidence, and this received a considerable stimulus from the publication of Sir C. Lyell's "Antiquity of Man" in 1863.

Early in 1864 I suggested to Sir C. Lyell that an application should be made to the British Association, during the meeting to be held at Bath that year, for the appointment of a Committee, with a grant of money, to make an exploration of Kent's Cavern, and it was decided that I should take the necessary steps in the matter. [This Committee was appointed and a grant made by the Association.] The mode of exploration was essentially the same as that followed at Windmill Hill, Brixham, but as Kent's Cavern, instead of being a series of narrow galleries, contained a considerable number of spacious chambers, and as the aim of the exploration was to ascertain not merely what objects the deposits contained, but their exact position, their distribution, their condition, their collocation, and their relative abundance, the details had to be considerably more elaborate, while they remained so perfectly simple that the workmen had not the least difficulty in carrying them out under my daily superintendence.

Mr. Godwin-Austen, while agreeing with Mr. MacEnery that flint implements occurred under the stalagmite, contended that they were found throughout the entire thickness of the cave earth. MacEnery, on the other hand, was of opinion that in most cases their situation was intermediate between the bottom of the stalagmite and the upper surface of the cave earth; and while admitting that occasionally, though rarely, they had been met with somewhat lower, he stated that the greatest depth to which he had been able to trace them was not more than a few inches below the surface of the cave earth (*Trans. Devon. Assoc.* iii. 325-327). The Committee soon found themselves in a position to confirm Mr. Godwin-Austen's statement, and to say with him that "no distinction founded on condition, distribution, or relative position can be observed whereby the human can be separated from the other reliquiæ" (*Trans. Geol. Soc.* 2nd ser. vi. 444). Mr. MacEnery's "Plate F" contains seven figures of three remarkable canine teeth, which in 1846 Prof. Owen assigned to *Machairodus latidens*. A considerable amount of scepticism existed for many years in some minds as to whether the relics were really found in Kent's Cavern, it being contended that from its zoological affinities *Machairodus latidens* must have belonged to an earlier fauna than that represented by the ordinary cave mammals; but there is no longer any doubt of MacEnery's accuracy; no doubt that *Machairodus latidens* is a member of the cave earth fauna, whatever the zoological affinities may say to the contrary; nor is there any doubt that man and *Machairodus* were contemporaries in Devonshire.

When their exploration began, and for some time after, the Committee had no reason to believe or to suspect that the cavern contained anything older than the cave earth; but at the end of five months, facts, pointing apparently to earlier deposits, began to present themselves; and at intervals more or less protracted, additional phenomena, requiring apparently the same interpretation, were observed and recorded; but it was not until the end of three full years that a vertical section was cut, showing, in undisturbed and clear succession, not only the cave earth with the granular stalagmite lying on it, but, under and supporting the cave earth, another, thicker, and continuous sheet of stalagmite—appropriately termed crystalline—and below this again an older detrital accumulation, known as the breccia, made up of materials utterly unlike those of the cave earth.

The breccia was just as rich as the cave earth in osseous remains; but the lists of species represented by the two deposits were very different. It will be sufficient to state here that, while remains of the hyæna prevailed numerically very far above those of any other mammal in the cave earth, and while his presence there was also attested by his teeth-marks on a vast number of bones, by lower jaws—including those of his own kith and kin—of which he had eaten off the lower borders as well as the condyles, by long bones broken obliquely just as hyænas of the present day break them, and by surprising quantities of his coprolites, there was not a single indication of any kind of his presence in the breccia, where the crowd of bones and teeth belonged almost entirely to bears.

No trace of the existence of man was found in the breccia until March, 1869, that is about twelve months after the discovery of the deposit itself, when a flint flake was met with in the third foot-level, and was believed to be not only a tool, but to bear evidence of having been used as such. Two massive flint implements were discovered in the same deposit in May, 1872, and at various subsequent times other tools were found, until at the close of the exploration the breccia had yielded upwards of seventy implements of flint and chert.

While all the stone tools of both the cave earth and the breccia were Palæolithic and were found inosculating with remains of extinct mammals, a mere inspection shows that they belong to two distinct categories. Those found in the breccia—that is, the more ancient series—were formed by chipping a flint nodule or pebble into a tool, while those from the cave earth—the less ancient series—were fashioned by first detaching a suitable flake from the nodule or pebble, and then trimming the flake—not the nodule—into a tool.

It is worthy of remark that in one part of the cavern, upwards of 130 feet in length, the excavation was carried to a depth of nine feet, instead of the usual four feet, below the bottom of the stalagmite; and that, while no bone of any kind occurred in the breccia below the seventh foot-level, three fine flint nodule tools were found in the eighth, and several flint chips in the ninth, or lowest foot-level.

It may be added that the same fact presented itself in the lowest or corresponding bed in Brixham Windmill Hill Cavern. In short, in each of the two famous Devonshire caverns the archæological zone reached a lower level than the palæontological.

That the breccia is of higher antiquity than the cave earth is proved by the unquestionable evidence of clear undisturbed superposition: that they represent two distinct chapters and eras in the cavern history is shown by the decided dissimilarity of the materials composing them, the marked difference in the osseous remains they contained, and the strongly contrasted characters of the stone implements they yielded; and that they were separated by a wide interval of time may be safely inferred from the thickness of the bed of stalagmite between them.

It is probable, however, that the fact most significant of time and physical change is the presence of the hyæna in the cave earth, or less ancient, but not in the breccia, or more ancient, of the two deposits. Bearing in mind the cave-haunting habits of the hyæna, the great preponderance of his remains in the cave earth, and their absence in the breccia, it seems impossible to avoid the conclusion that he was not an occupant of Britain during the earlier period.

The acceptance of this conclusion, however, necessitates the belief (1) that man was resident in Britain long before the hyæna was. (2) That it was possible for the hyæna to reach Britain between the deposition of the breccia and the deposition of the cave earth. In other words, that Britain was a part of the Continent during this interval.

Sir C. Lyell, it will be remembered, recognised the following geographical changes within the British area between the Newer Pliocene and historical times (see "Antiquity of Man," edition 1873, pp. 331, 332). Firstly, a pre-Glacial Continental period, towards the close of which the Forest of Cromer flourished, and the climate was somewhat milder than at present. Secondly, a period of submergence, when the land north of the Thames and Bristol Channel, and that of Ireland, was reduced to an archipelago. This was a part of the Glacial age, and icebergs floated in our waters. Thirdly, a second Continental period, when there were glaciers in the higher mountains of Scotland and Wales. Fourthly, the breaking up of the land through submergence, and a gradual change of temperature, resulting in the present geographical and climatical conditions.

It is obvious that if, as I venture to think, the Kent's cavern breccia was deposited during the first Continental period, the list of mammalian remains found in it should not clash with the list of such remains from the Forest of Cromer, which flourished at that time. I called attention to these lists in 1874, pointing out that according to Prof. Boyd Dawkins (Cave-Hunting," p. 418) the forest bed had at that time yielded twenty-six species of mammals, sixteen of them being extinct and ten recent: that both the breccia and the forest bed had yielded remains of the cave-bear, but that in neither of them had any relic or trace of hyæna been found. A monograph on the "Vertebrata of the Forest Bed Series" was published in 1882 by Mr. E. T. Newton, F.G.S., who, including many additional species found somewhat recently, but eliminating all those about which there was any uncertainty, said: "We still have forty-nine species left, of which thirty are still living, and nineteen extinct" (p. 135). Though the number of the species has thus been almost doubled, and the presence of the cave-bear remains undoubted, it continues to be the fact that no trace of the hyæna has been found in the forest bed, and no suspicion exists as to his probable presence amongst the eliminated uncertain species. It should be added that no relic or indication of hyæna was met with in the "Fourth Bed" of Brixham Windmill Hill cavern, believed to be the equivalent of the Kent's Hole breccia. I am not unmindful of the fact that my evidence is negative only, and that raising a structure on it may be building on a sandy foundation. Nevertheless, it appears to me, as it did ten years ago, strong enough to bear the following inferences:—1. That the hyæna did reach Britain until its last Continental period. 2. That the men who made the Palæolithic nodule-tools found in the oldest known deposit in Kent's Cavern arrived during the previous great submergence, or, what is more probable—indeed, what alone seems possible unless they were navigators—during the first Continental period. In short, I have little or do doubt that the earliest Devonians we have sighted were either of Glacial or, more probably of pre-Glacial age. It cannot be necessary to add that while the discovery of remains of hyæna in the forest bed of Cromer, or any other contemporary deposit, would be utterly fatal to my argument, it would leave intact all other evidence in support of the doctrine of British Glacial or pre-Glacial man. Some of my friends accepted the foregoing inferences in 1873, while others, whose judgment I value, declined them. Since that date no adverse fact or thought has presented itself to me; but through the researches and discoveries of others in comparatively distant parts of our island, and especially in East Anglia, the belief in British pre-Glacial man appears to have risen above the stage of ridicule, polis last year exceeded two and a quarter millions sterling, equal to 1s. 6d. in the pound on the present annual rateable value of property; and that of this sum, probably, at least one million would have been saved by a system of hydrants with an adequate water supply, such as those which have existed for many years in Liverpool, Manchester, and Glasgow. The water supply of London, however, although satisfactory as to quantity, has not sufficient pressure for hydrant purposes, and from the fact that the supply has to be pumped up from a low level, instead of coming by gravitation from high sources — as in the towns referred to—it is impossible, without enormous expenditure, to adapt it for hydrants. Sir William Armstrong's accumulator system of hydraulic power, generally in use at the docks and goods termini, requires no description. In connection with the injector hydrant it has been found to be specially applicable to the production of jets of water for fire extinction in cases where the ordinary supply has not sufficient pressure for the purpose. Applied to the metropolis generally in the same way it would funish a complete and efficient system of fire hydrants, without imposing upon the ratepayers any additional burden; and if the hydraulic power were applied to commercial purposes there would result a considerable gain to them.

On the Magnetisation of Iron and Steel.

Sir William Thomson then read a communication "On the Magnetic Susceptibility and Retentiveness of Iron and Steel" from Mr. J. E. Ewing. The author said that he had been experimenting in Japan on the effect of stress in relation to magnetisation, and he had demonstrated the hitherto unsuspected fact that soft iron is capable of an immensely greater degree of magnetisation than steel. The method employed was to subject wires to the magnetising force, tapping them during its application and withdrawing it gradually. When this plan was followed 93 per cent. of the charge remained. He had obtained magnetic intensity of 1,590 units, while Thalen only obtained 40 from soft Swedish iron, and Roland 200. This result, Sir William Thomson said, was a satire on our knowledge of magnetism. The author also stated he had computed the heating effect of the reversal of the induction in iron in absolute measure.

Electrical Standards.

Mr. R. T. Glazebrook read the report of the Committee on Electrical Standards, which explained that the original B. A. units had been compared between themselves, and the mean had been taken as the standard. Several resistance coils had been submitted for examination, and had been returned with certificates to the effect that they had been compared with the B. A. units, and that at *a* deg. Cent. the resistance equalled *p*. B. A. units, or p^1, Rayleigh ohms (1 B. A. units = .9867 Rayleigh ohms). The coefficient of variation for temperature was not stated, as it could be determined by any electrician for himself. The original standards were single units, and during the year ether standards of 10, 100, and 1,000 units had been made from them, under special precautions as regards accuracy, which he described in detail. He also stated that Dr. Muirhead had completed three air condensers as standards, and that the Committee asked to be reappointed.

Secondary Batteries.

After the reading of a paper on electrical launches, Sir W. Siemens said that from his knowledge of the behaviour of these launches they promised excellent results. The question was, What was the secondary battery going to do for us? Was it going to last, or was it a perishable institution? In order to test the question quietly he put down secondary batteries in his own house last autumn. He charged them by means of a very small half-horse power engine, and the result so far had been very satisfactory. He had lighted his house by the small engine with the aid of the secondary battery with great effect, using 40 incandescent lamps from half-past 7 in the evening until 1 or 2 o'clock. He started his engine at 8 o'clock in the morning, and in the evening he had a sufficient accumulation of energy in the battery to last the length of time it was required. In the case of the launch the machine could not be taken with it, and the batteries would occasionally have to be charged. Therefore, he would limit the application of the electric power to navigation to short stages. The cost of the use of steam power and electric storage would be about equal, but the latter would give advantages in weight and space.

An Impregnable Safe.—The National City Bank at Cleveland lately found that the time-lock of its safe was out of order. All efforts to open it having proved fruitless, the masonry in which it was embedded had to be pulled down, and the safe conveyed to some neighbouring ironworks, and there blown open with dynamite.

SCIENTIFIC SOCIETIES.

LIVERPOOL ASTRONOMICAL SOCIETY.

THE third session of this Society was opened on Wednesday, 26th September, under extremely favourable circumstances, both so far as the attendance was concerned and in the selection of the speakers. The chair was occupied by the president (Mr. R. C. Johnson, F.R.A.S.), who said it was customary on the first evening of a session for the president to deliver an opening address. They had had the good fortune, however, to secure the attendance of Professor E. C. Pickering, who had been kind enough to take this duty upon himself. He was sure they would be anxious to hear the remarks of Mr. Pickering, so he would, without trespassing upon their patience, introduce him.

Professor Pickering, who was received with applause, said: Mr. President, the encouragement of astronomy, which your society has in view, is an important work, and it gives me great pleasure to address you. I would speak to-night more particularly about the work to be done in connection with stellar light and stellar variation. In this branch of astronomy valuable work can be done with the unassisted eye or with a small telescope or opera glass. First of all, as regards star magnitudes, the earliest catalogue, that of Ptolemy, dates nearly 2,000 years ago. In it the determinations of brightness are shown by numbers. The faintest star has the number *six* affixed, and the brightest, one. But as there are many stars of the same magnitude and yet differing slightly in brightness, the Greek letters *μ* or *ε* were affixed, signifying the words *μειζων* or *ελασσων* (greater or less). Various copies of this work are in existence, and valuable work might be done by a gentleman, who possessed classical and astronomical skill, compiling the differences of these copies. The variation between the MSS. is very considerable. Baily found that the assigned magnitudes, or positions, varied in three-fourths of the total number of stars. The great authority at present is a 9th-century MS. at Paris, in the national library. A century ago Sir W. Herschel commenced his photometric measures, his method being to speak of a star as brighter or fainter than some other star. He designated small differences of magnitude by means of a period, a comma, or a dash, and their combinations; four catalogues are given in the "Philosophical Transactions." They attracted little attention, however, as there were no absolute determinations of magnitude. At Harvard College all the stars, down to 6th mag., inclusive, have been photometrically observed, and by means of these measures we have been able to represent in numbers the estimates of Herschel. But these four catalogues refer only to parts of the sky. Only two-thirds are there given. Whilst in London I was allowed, by the kindness of the possessors of the original manuscripts of Sir W. Herschel, to inspect them, and amongst them I found two more catalogues which had remained unpublished. A note was attached in Miss Caroline Herschel's handwriting, stating that they were ready for the press. They had been left to Sir John Herschel, and probably through pressure of work he did not publish them, or else did not realise their value. I was allowed to make a copy of these two catalogues, and have forwarded them to Harvard. No similar work of equal accuracy has appeared till within the last ten years. Half a century later Argelander, the greatest observer perhaps who has ever lived, discovered the same method independently, and for a long time—so slow was intercommunication in those days—was not aware of Sir W. Herschel's earlier work. Argelander's method is one of the most precise. The principal difference between his and Herschel's is, that the former used a notation while he used numbers. If the difference was small, he called it "one grade," if distinctly visible, "two grades," and so on. There are 25,000 observations of his in the "Bonn Observations." The great difficulty at present which any one studying the magnitudes of the stars as they were in former years encountered is that the various observations of them are scattered far and wide in various periodicals. The results of these observations we hope to collect in one volume. While at Bonn I was allowed to see Argelander's observations. There were some 3,000 or 4,000, referring to the variable stars. By the kindness of Professor Schönfeld I was allowed to copy them. As many of them were written in the dark, probably with the eye at the telescope, it was a work of some difficulty to decipher them. The amount of unpublished observations is very great. No piece of work is accessible to all till it is printed. At present I find, speaking from memory, that there must be nearly 170,000 unpublished observations, and not more than 40,000 published. It is greatly to be regretted that they should thus be left to accumulate, and perhaps in the end never get into print. Here let me point out a source of error liable to occur in Argelander and Herschel's method. This is due to the effect of one star's position with regard to another. Two stars, apparently equal, show a difference when placed one above the other. Through the varying positions of the stars, as presented to the observer, have arisen many of the cases of suspected variations. The suspected variable stars amount to no fewer than 1,500, according to the list compiled at Harvard; but many of them may have been suspected of variation through the cause just mentioned. Valuable contributions would be made to our knowledge if it could be determined why this apparent variation, due to position, exists. How very remarkable it is, is shown by our observations to determine the constancy of the Pole star. To accomplish this we compared it with several other stars. The method was, each evening, to look at the Pole star, and then at the other star, and see which was the brightest. We soon found a marked deviation; for instance, comparing it with *γ* Cassiopeiæ, we found it $\frac{3}{10}$ths fainter, and the difference in a year amounted to half a magnitude. Other stars gave similar results; but it was found that while *γ* described a curve in one way, *ε* deviated in the opposite way. The same result was obtained with *β* Ursæ Minoris. Arranging observations according to position, we got curves, and found on applying the correction for position that the curves became equal. The question is worthy of further investigation, and I would suggest the following ways:—(1) To look at the stars near the Pole at different seasons of the year, or, as can be done more conveniently, in your greater northern latitude early in the evening and late in the morning; (2) by inverting the positions by means of a looking glass; (3) by watching stars in the zenith lying down on the ground, and then turning round and looking up at them in a different position. The brightest stars are less important than the fainter ones, because sufficiently observed elsewhere. The stars below the 6th mag. are very little observed. Valuable work might be done by determining the magnitude of the stars visible in an opera glass, in the manner of Argelander and Herschel; and especially I would recommend those stars near the Pole. Another piece of work not less valuable might be done in determining the brightness of Uranus and Neptune, and of the Asteroids, some of which are probably variable. We know that one of the satellites of Saturn, Japetus, varies very greatly in light; and it has been suggested, with great probability of truth, that one side is capable of reflecting more light than the other, and so we have a means of determining the time of rotation through observations of its variation. The Asteroids may vary in the same way; and the value of the observations lies in the fact that we shall thus have a probability of finding the time of rotation on their axes. Similar observations of Uranus and Neptune might be made; but, probably, the differences would not be large. Not much value can be assigned to the times of rotation of these planets as hitherto determined. But this method of watching the variation may be valuable as determining the times of rotation of those bodies on which we are not able to see markings. Thus it is impossible to measure the diameters of the fixed stars, as we never have, and, in all probability, never shall be able to observe their discs. The diameter of the brightest star does not exceed a few hundredths of a second of arc, corresponding to as many feet at a distance of 4,000 miles. But it may be possible to tell the size of bodies whose discs are invisible with precision. For instance, in 1877 and 1879 we made determinations of the brightness of the satellites of Mars, and found that, if of the same material as Mars, they could only have a diameter of six or seven miles. We can tell their relative diameter by their measures with greater accuracy than has yet been attained for Mars itself. Again, Vesta might be compared with various stars throughout the year; by this means a list of comparison stars would be obtained, stretching right round the heavens. Another advantage would be that as the Asteroid varies with its distance from the earth, we can compute what the variation should be, and so correct our eye estimation. Another field is one in which good work is being done by your society—viz., the observation of suspected variable stars. The greater part of these are visible to the naked eye, and are thus easily observed, so that the greater part of the work may be done without any instrumental help. A great point would be gained, even if the results were purely negative, as these stars could then be removed from the lists of suspected variables. Yet another point is the observation of the variation of absorption. This consists merely of watching stars, and estimating the brightness of stars on the horizon and in the zenith. All that is necessary is to compare carefully a star on the horizon with a star near the zenith. These observations should be made in various places. In America the pure sky of Italy has become proverbial, and I had hoped to have reduced this poetical saying to a mathematical figure. But, with the exception of one opportunity, I was unable to make the determinations I had intended doing while travelling from place to place. This exception was an the Rhigi, with a field glass. Some stars near the horizon were compared with stars in the zenith, and I hope hereafter to reduce the results thus obtained. But the subject commends itself to travellers, and I hope any member of your Society, who has the chance, may attempt this kind of work.

The President said a communication had been received from Mr. E. F. Sawyer, of Cambridgeport, U.S.A., on some observations he had made on the variable star R Coronæ, from 1881 to the present time. He suggested that this star should be closely watched by astonomers.

The Rev. T. E. Espin, B.A., gave a brief account of the work done at the Society's observatory.

Eight candidates were proposed for election, and the proceedings closed with a vote of thanks to the lecturer.

SCIENTIFIC NEWS.

AT the closing meeting of the British Association, Prof. Cayley, the president, stated that Southport had done everything it could to make the meeting a success, and Prof. Williamson reported that the attendance had been over 2,700—more than were present at the York meeting. The new annual members numbered 323, the associates 952, and the ladies 841.

Altogether a total sum of £1,445 was apportioned in grants, the most remarkable item (in one sense) being £5 for patent legislation, the largest £500 for exploring Kilimanjaro and the adjoining mountains of Equatorial Africa; £80 is awarded to the biological table at Naples; £100 to the exploration of New Guinea; £75 for earthquake phenomena of Japan; £50 for meteorological observations on Ben Nevis; and £25 for the meteorological observatory near Chepstow. The remainder of the sum total is divided amongst the usual subjects.

Amongst the recommendations of sections approved by the Council, is one in which the Committee of the Fisheries Exhibition is urged to appropriate a sum of money to found a zoological laboratory on the British Coast; another is an application to the Admiralty to institute a biological survey of Milford Haven and the adjacent coast; and yet another is the suggestion to form a separate section for anthropology, leaving section D with the title biology, zoology, botany, and physiology.

The Council have taken the "election of members" under their control until further notice, for a reason which, in view of the visit to Canada, is obvious.

According to the *Times*, Dr. Schuster has "reduced to a decimal point the exact constitution of the sun."

Dr. Wentworth Erck writes that Comet Pons-Brooks was seen at Shankill, Bray, on Sept. 24. With 7½in. aperture, it presented the appearance of a nearly circular nebulous mass 2′ in diameter, with a slight central condensation. Dr. Erck says it can be seen with 1in. aperture, and will soon be visible in an opera-glass. The following extract from the ephemeris of MM. Schulhof and Bossert may be useful. It is for Berlin midnight:—

	R. A.			N. Dec.		
Oct. 5	16h.	29m.	48·20s.	57°	55′	43·1″
7	16	31	18·54	57	30	10·1
9	16	32	50·08	57	4	52·5
11	16	34	37·73	56	39	51·2

There are six known comets having calculated periods of about 70 years; but of these the only proved periodic is Halley's, which last appeared in 1835, and our present visitor, which there seems no reason to doubt is Comet Pons, 1812.

The Treasury having declined to defray the expenses of erecting a telegraph wire between the summit of Ben Nevis and Fort William, the Council of the Meteorological Society have determined to rent a wire of the Post Office, which will be available for the public service as well as for the purposes of the observatory.

The arrangements for the Gresham lectures during the present session are as follows:—Rhetoric (Mr. J. E. Nixon), Oct. 9th, 10th, 11th, and 12th; astronomy (Rev. E. Ledger), 16th, 17th, 18th, and 19th; geometry (Dean Cowie), 23rd, 24th, 25th, and 26th; law (Dr. Abdy), Oct. 30th and 31st and Nov. 1st and 2nd; divinity (Dean Burgon), Nov. 5th, 6th, 7th, and 8th; and music (Dr. H. Wyide), 13th, 14th, 15th, and 16th.

Mr. W. E. Crowther, of the Manchester Technical School, has written a circular letter, in which he regrets that the subject of Hygiene is "placed in a more unfavourable position financially than any other science subject" of the Science and Art Department. Mr. Crowther says that the department annually obtains from Parliament £340,000 or thereabouts, out of which only 5s. 9d. in the pound is given to the direct encouragement of national science and art instruction, the remaining 14s. 3d. being "absorbed" at South Kensington and Dublin. We cannot spare space to reproduce Mr. Crowther's letter; but he will, no doubt, supply copies to all interested, and it is specially interesting to science teachers and students.

The subject for the Howard Medal of the Statistical Society is "The Preservation of Health, as it is affected by Personal Habits, such as Cleanliness, Temperance," &c. The essays must be sent in by the 30th of June, 1884.

The Franklin Institute of Pennsylvania is making arrangements to hold an International Electrical Exhibition at Philadelphia, to open on Sept. 2, 1884. The Government has authorised the admission of all articles free from duty or customs fees, which will be payable only if the articles are sold or consumed in the United States. Full information can be obtained of the Secretary, Franklin Institute, Philadelphia, Penna., U.S.A.

An International Exhibition of Art, Manufactures, Science, and Industry will be held at the Crystal Palace from April 3 to October 31, 1884. Full particulars can be obtained of Mr. G. C. Levey.

The Department of Applied Science and Technology at University College, London, opened last Tuesday, under the direction of Prof. A. B. W. Kennedy, Prof. Vernon-Harcourt, Prof. C. Graham, and others. The instruction includes civil and mechanical engineering, surveying, drawing, and experimental work in the laboratory, chemistry in its various technical branches, architecture and construction. The engineering laboratory of this college affords an excellent opportunity for students to acquire practical knowledge of their profession.

It is stated that Mr. W. S. Cowell, of Lowell, Mass., has succeeded in making a bisulphide of carbon engine that is free from objections. We shall see.

The Pearl Life Assurance Company.—The nineteenth annual report of this company is one of continued prosperity. Two hundred and twenty-two thousand and thirty policies have been issued during the year, representing a new annual premium income of £103,837 15s. 8½d. Premiums from one halfpenny per week may now be paid either weekly, monthly, quarterly, half-yearly, or yearly, to meet the requirements of all classes. The total amount of premiums received by the company for the twelve months ending June last amounted to £126,239 8s. 7d., being an increase of more than £16,000 over the previous year's income. On the policies in force on the company's books at the end of the financial year the annual premium income equalled £153,661 10s. 8d. Seven thousand four hundred and ninety-one claims and grants, amounting to £44,877 19s. 7½d., have been paid by the company in the twelve months ending June, 1883, and the amount paid by the company since its incorporation equals £225,482 16s. 6d. At the Victoria Hall, Sunderland, fifteen of the company's policyholders lost their little ones, on behalf of some of whom only a few pence had been paid. The representative was, however, in all cases instructed to settle their claims at once and in full.

The *Neueste Erfinderung* describes an anti-corrosion paint for iron. It states that if 10 per cent. of burnt magnesia, or even baryta or strontia, is mixed cold with ordinary linseed oil paint, and then enough mineral oil to envelop the alkaline earth, the free acid of the paint will be neutralised, while the iron will be protected by the permanent alkaline action of the paint. Iron to be buried in damp earth may be painted with a mixture of 100 parts of resin (colophony), 25 parts of gutta-percha, and 50 parts of paraffin, to which 20 parts of magnesia and some mineral oil have been added.

To encourage tree planting the legislature of New York State passed a law by which any inhabitants who shall transplant by the side of the public highway adjoining his premises any forest shade trees, fruit trees, ornamental trees, or any nut-bearing trees, shall be allowed, in abatement of his highway tax, 1 dol. for every four trees set out. Elms must be placed not less than 70ft. apart on the same side of such highway, and no maples or other forest trees, ornamental, or fruit tree, nearer than 40ft. apart on the same side of such highway.

LETTERS TO THE EDITOR.

[*We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.*]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, 31, *Tavistock-street, Covent-garden, W.C.*

All Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

⁂ *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

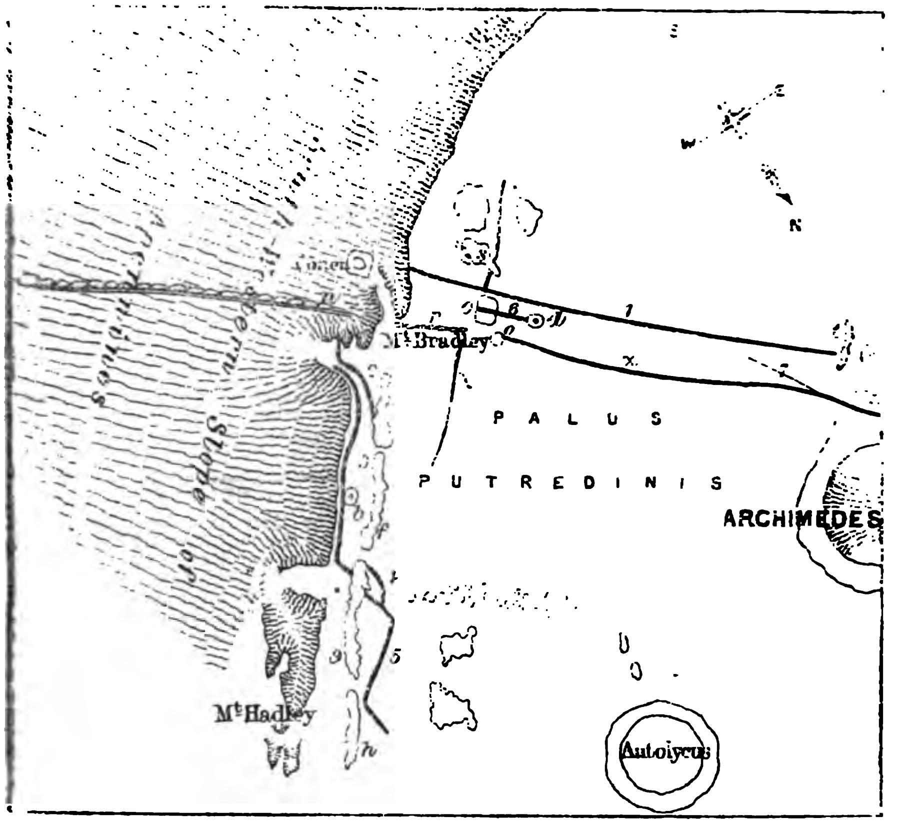
"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original."
—*Montaigne's Essays.*

ASTRONOMICAL—β DELPHINI—δ EQUULEI.

[21876.]—As there is nothing like trying, I thought, after reading letter 21796, that I might turn my telescope on δ Equulei and β Delphini, to see what I could do. The air was good, but not as good as one would like when examining such very delicate and difficult objects with an 8½in. mirror. β Delphini was seen at once, eggshaped, and with power about 1,000, at times notched at very short intervals, the companion being seen in position 200° ±. I have examined it several times afterwards, and always with the same results. I have found δ Equulei more difficult than β Delphini, and I cannot be so sure of the position of the *comes*. On Sept. 15 and 16 I thought the companion was in position 20° ±; but on the 18th, and with power 450 ±, it seemed to me it was in position 130° ±. I again noticed on this occasion that it is more difficult than β Delphini. Will "H. S." tell me if I have seen right, or if what I have seen is the result of a faulty adjustment? I hope Mr. Perry will soon give us his measures. **C. Gaudibert.**

SELENOGRAPHICAL — CLEFTS BETWEEN ARCHIMEDES AND THE LUNAR APENNINES—ARCHIMEDES.

[21877.]—ON 22nd September, 13h. to 15h., the longitude of the terminator being about 14° west, I obtained an unusually fine view of some of the clefts which extend from the hilly region on the S.W. side of Archimedes to the Apennines in the neighbourhood of Mt. Bradley, and also of a remarkable group which runs parallel, or nearly so, to this grand mountain system. The accompanying diagram shows the general direction of those observed; but, of course, can convey no idea of the extreme delicacy of most of them, nor of the beauty of their surroundings under almost perfect definition with a power of 350 on my 8½in. Calver reflector. In comparing my sketch with B. and M.'s, and Neison's map, I recognise χ as answering to the cleft so lettered by them. This delicate object commences as a valley on the S.E. side of Archimedes, and appears to terminate *as a cleft* a little to the E. of Mt. Bradley; a row of hillocks bounding a valley, traceable through all the intricate detail of the slope of the Apennines to *m*, seems to follow the direction of its imaginary prolongation from *n* to *m*, towards the S.W. This coincidence of direction between the cleft χ and the narrow valley *n m* can hardly be fortuitous, though the vast difference of level, amounting to thousands of feet, between the latter and the cleft on the plain beneath renders the connection between the two features strange if true. A very faint, short cleft, 7, was seen branching from χ near the well-known spur on the S. slope of the wall of Archimedes and proceeding towards cleft marked 1. The latter cleft was easily traced from the escarpment of the Apennines E. of Conon to a ridge *t*, south of Archimedes. It seems to agree with Neison's χ^2, though in his map IX, it is shown as terminating near the cleft λ. Between the clefts χ and 1 I remarked a short cleft 6, passing through the object *c* and terminating at a craterlet *d*. The S.E. portion of the cleft λ was very distinctly defined. It appears to be continuous till it encounters a spur from the low mountain *s*. A second interruption occurs where it meets cleft 1, and, though it was not traced between clefts 1 and χ, it became again prominent on the N.W. side of χ, and could be seen extending far away across the *Palus Putredinis* towards cleft 5, with which, probably, it is connected. Running nearly parallel to the escarpment of the Apennines from near Mt. Bradley to Mt. Hadley, is a range of hills or ridges marked *f*, *g*, *h*; and between these and the mountain range is a well-marked cleft 3, which was traced close under the foot of the cliffs, passing between it and a craterlet *b*, to the south side of the hill *g*. Another cleft, 2, curves round the E. side of the cliff concentrically with it, and runs to th



W. side of the hill *f*. A third cleft 5, was traced from the E. side of *g*; at first taking a N. direction, it suddenly turns to the N.W. till it reaches E. side of *h*, when it again trends N. for a short distance. A fourth cleft, 4, branches out from 5 and curves round to E. side of *g*, as shown. There can be little doubt if this region were carefully scrutinised with sufficient optical power, especially near lunar sunset, a large addition to the clefts at present known would be made, and, possibly, new light thrown on the origin of these (at present) inexplicable formations.

Archimedes.—In reference to letters Nos. 21706, [illegible], relating to the light streaks on the floor of Archimedes being seen to cross the W. wall and extend beyond it, I may inform Mr. B. J. Hopkins and Mr. F. S. Davenport that I have frequently remarked this peculiar phenomenon when Archimedes is under a high sun. A noteworthy fact in connection with it is that those portions of the wall and glacis which are traversed by the light bands are then abnormally bright.

Kempston, Beds. **Thos. Gwyn Elger.**

SELENOGRAPHICAL—ARCHIMEDES—CLEFTS NEAR MESSIER A.

[21876.]—Your correspondents Mr. B. J. Hopkins (let. 21706) and F. T. Davenport (let. [illegible]) must not suppose that the prolongation towards Autolycus of the rays crossing the floor of Archimedes is new. I have seen it myself again and again, and Dr. Julius Schmidt notices it in his observations of April 21, 1858. It is visible near or in full moon.

On Sept. 25, 1877 (Eng. Mech. No 655, p. 116), I discovered a cleft on the N.E. side of Messier A. I had no opportunity of seeing it again until Sept. 28, 1883, when a prolongation of the same was seen from crater 10 to near crater 17. Another cleft was also seen, running in a N.—S. direction, passing where the letter H is placed in my sketch, and nearly reaching the old cleft, with which it would form a right angle if it did reach it. The sides of this last cleft are very much broken, and it runs in very short zigzags.

I am sorry to see that no signs of the labours of the Selenographical Society are published in your pages. This silence makes one regret the time when the English Mechanic was the means of conveying to its readers so much interesting information on this branch of astronomy.

Sept. [illegible]. **C. Gaudibert.**

VISIBILITY OF VENUS DURING SEPTEMBER.

[2187[illegible].]—Mr. Flanks (letter 21851, p. 86) is quite correct in his surmise that our "Astronomical Notes" are intended "for the possessors of moderate-sized telescopes": but even they, we venture to think, would scarcely care to employ them (as a mere *tour de force*) in the finding of, and gazing at, a sensibly circular little disc of less than 10″ in diameter in the glare of sunlight. Had Venus been coming into inferior conjunction we should most assuredly have continued our ephemeris during the whole period, as she would then have presented an all-repaying spectacle to the observer when once fairly caught. Under existing circumstances, the exigencies of space in the columns of the English Mechanic compel us to exclude everything that is not of immediate interest to the amateur observer. It will doubtless be possible to find Venus during October. As to what satisfactory scrutiny of her can be made, or how far she will be worth looking at when found, we shall be glad to have the opinion of our readers.

The Writer of the Astronomical Notes.

THE LIVERPOOL ASTRONOMICAL SOCIETY.

[21880.]—In matters celestial I do not think there is much that would escape the notice of our energetic observer, but he has missed a point in his reference to the Liverpool Astronomical Society that I should like to call attention to. It appears to me that the title of the Society is, in itself, likely to create an impression that it has been established solely for the convenience of local amateurs. This feeling is, indeeed, evident in many of the letters I have received, and I am afraid that much valuable co-operation has been altogether withheld for this reason alone. It should be remembered that astronomy differs from most sciences in being independent of locality, and that celestial observations are, in fact, the more reliable in proportion to the difference in distance and other conditions under which they are made; therefore I hope that none of "Ours" will refrain from joining, simply because they happen to live a few hundred miles away. It is true, as Mr. Espin has said, that "from every side the most cordial support of well-known astronomers has been received," and how can we better show an appreciation of their kindness than by collecting large numbers to benefit by their instructions?

The annual subscription of 5s. is, of course, merely nominal, and would not nearly cover the expenditure in a small society. That we commence our third session with a small surplus is certainly a hopeful sign; but much more is needed before we can take the position we finally hope to do, as intermediate to the amateur public and the Royal Astronomical Society.

W. H. Davies.

Hon. Sec. Liverpool Astronomical Society.

PROFESSOR BALL ON THE MEASUREMENT OF THE SUN'S DISTANCE.

[21881.]—In his address on this subject, as appearing in the Mechanic, he says that if it were possible to transplant the instrument and apparatus, operator, and all after measuring, &c., to the other station, &c., the means would be attained. As this will be an impossibility, "Mohammed" must go to the mountain if the mountain won't come to him, and that it will not. It has occurred to me that were two stations in electric communication, and the instant of measuring at them thereby known the thing would be done. And why, if this can be done, every station in the world could be in electric communication with each other. Practically knowing as I do nothing of the instruments and apparatus used by astronomers, I cannot say anything beyond the fact that the means of instant communication over this globe is in their hands and at their service by the electric telegraph, and if the game is worth the candle, I cannot see why it should not be used. Then, again, if the telephone, which from all accounts has been brought to travel great distances, is used, it will become of the most certain advantage.

P. W. R.

WOODEN CHUCKS.

[21882.]—Of the wooden chucks mentioned by Dr. Edmunds (page 62), I cannot speak from comparison, having neither spring nor self-centring ones, but I can fully corroborate their efficiency and exactness for delicate work, such as microscopic apparatus, with which I have been for some time amusing myself. At first I used yew, but gave it up for beech, which, I think, has a better grip. Instead of fitting a chuck upon the mandrel, I drive a piece of wood into a bell-chuck, leaving about 2in. clear to work upon, which often serves me for a good while. My mandrel not being drilled throughout, but only about a third of its length, the hole terminating in a slot, I cannot tap the work out so readily; though I must tap it out when it is a small surface that is being faced up. Generally I put a small brass disc faced with leather into the chuck before the work, which has a threaded hole in its centre, so that a piece of thick wire can be screwed into it, and the work easily and safely drawn out when finished, or before, for I frequently take out and replace, without any sign of "off true." I give this for the benefit of "non-drilled mandrels," who may be apt to mar a bit of delicate work in trying to pick it out.

J. A. C.

LATHE MANDRELS.

[21883.]—At the courteous invitation from Dr. Edmunds, I beg to offer the following criticisms on his standard mandrel:—I would propose 1in. instead of 1·05 for the cylindrical portion of the nose, and ·95 for the diameter of the screw. The former, being the most important part as regards securing immobility and the interchange of chucks, should have the simpler dimension, and this would best be given in the mode proposed by **A "Fool."**

ORNAMENTAL TURNING AND THE PROPOSED STANDARD MANDREL.

[21884.]—General Clarke's help on the question of a standard mandrel will be of great value. He is not a mere manufacturer of "gimcracks in ivory and blackwood," but a leader-artist in ornamental lathework, and one who will be as ready to see justice done to the facts as to Mr. Holtzapffel. If I have done any injustice to Mr. Holtzapffel, I shall be anxious to set myself right: but at present I have only to point out the General's carelessness in imputing to me words which I had not used. I never described the engraving as "Mr. Holtzapffel's ideal of a *mandrel*-nose."

The engraving in question had been drawn and published by Mr. J. J. Holtzapffel as a model for cutting "the hardwood or ivory external screw, of large or small diameter." In the text of my paper I point out how the engraving differs from his steel mandrel-nose, and nowhere do I speak of his steel mandrel-nose as being represented by this engraving otherwise than in its general character. My words are: "Certainly the engraving represents the shallow thread used for ivory, hardwood, or cast-iron, and is flattened off at the top much more than is the deep thread used upon the steel mandrel-nose; but the measurements of the lathe-noses (table VIII.) show that, in other respects, it represents very fairly Mr. J. J. Holtzapffel's notion of an ideal screw-nose. Against that ideal for a screw-nose of any sort—wood, ivory, or metal—I beg leave to enter a protest."

I gave the dimensions of Fig. 512, which I will call the ivory screw-nose, as follows:—Length, ·870in.; diameter, outside thread, ·770in.; at bottom of thread, ·570in.; in groove at base of nose, ·470in. The threaded nose has a diameter midway between the full cylinder and the stem = ·670in., and gives a sectional area of ·3526 square inch, while the base of the nose at the point where all the strain falls has a diameter of ·470in. and a sectional area of ·1735 square inch. My reproduction is a close facsimile of Mr. Holtzapffel's engraving, and my figured measurements are correct. I reproduced the engraving in order to give substance to a protest against such a model being set up before us for any screw-nose whatever whether in wood, ivory, or metal.

Not only did I never represent the Holtzapffel mandrel-nose as like this ivory screw-nose, but I names, and in consequence, what is called negative is, in fact, the true positive state. As a parallel example, a compass needle points to the north, and the end that does so is called the north pole, although it really possesses the same kind of magnetism as the true south pole of the earth.

In a galvanic battery, the carbon terminal is commonly called positive; but the electric current is thought to pass from the zinc terminal along the wire to the carbon, and that the carbon serves only as a conductor, it having no electric action whatever.

Positive electricity only is considered to exist; the negative is merely a lower positive state; just as ice is hot or in a positive state when compared with frozen quicksilver, or hot water is cold or negative compared to melted iron. The experiment with the card only proves that a hole is made in the card with a burr on each side: the phenomenon can be explained several ways. **J. Sutcliffe.**

THEORY AND CONSTRUCTION OF THE HELIOSTAT.—III.

A Heliostat with one Reflection.

[21888.]—The instrument about to be described is in principle similar (or so the writer believes) to that of Gambey; but it has received some improvements from Mr. Johnstone Stoney. Its geometrical theory was described on page 41 of this volume. The following are practical directions for constructing it. It ought to be premised, however, that the cut, Fig. 5, is not taken from one of those instruments ordinarily sold, having a wooden base and a French clock attached by a band; but is taken from a photograph of one in the writer's possession, and no instrument-maker is responsible for it. At the same time it is one which performs well, and appears to the writer to be more easily constructed by an amateur who, though possessing a tolerably well appointed workshop, is yet unable to do "dividing" with any accuracy.

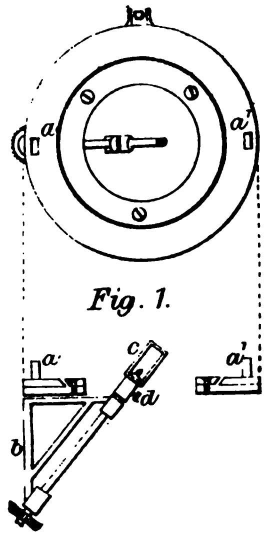


Fig. 1.

Those, however, who prefer Stoney's form will see a good cut of it on page 271 of the last edition of "Captain Abney's Photography."

The first thing to do is to prepare patterns for the three brass rings seen in Fig. 1. One of these, the lower, is 5in. outside diameter and 3in. inside; the other two when put together make a ring the same size and shape as the first, but are arranged as seen in the figure, so that when the inner ring is screwed down to the lower one, as shown, the outside upper ring can revolve stiffly on the others in its own plane, being held down by the slant edges of the inner ring.

These rings must be cast, faced, and turned up true in the lathe. *A* and *a'*, Fig. 1, are two little pieces which may either be cast in one piece with the movable ring, or attached afterwards.

They should be accurately set on a diameter of the ring and equidistant from the edge. Their office is to serve as bearings in which the piece, Fig. 3, can turn about the screw-centres A B.

The piece *b*, Fig. 1, should next be cast and screwed to the under ring. It must be so constructed that the line of the holes in which the polar axis is destined to revolve shall make with the shorter side of the piece an angle equal to the latitude of the place where the instrument is to be used. It must not be attached to the ring until the polar axis, presently to be described, is ready, as the necessary adjustment involves the three pieces at once. The polar axis is seen in Fig. 1 and Fig. 2. It consists of a piece of bright steel rod fitting nicely through the holes in the piece *b*, and having a piece of brass slipped over its upper end of the shape shown in the figure. This piece, *c*, Figs. 1 and 2, is to form a bearing for the sun-pointer *a c*, Fig. 2. It should fit over the polar axis without play, but not too tight to revolve independently. A small screw *d*, Figs. 1 and 2, will clamp it to the axis when the instrument is working. Two bevel wheels must be procured (it is assumed that no facilities for cutting them at home will probably be possessed). One of them *b*, Fig. 2, must have twice as many teeth as the other, and they must be so cut as to work when their axes are at an angle equal to the latitude. These can be procured in London for about 2s.

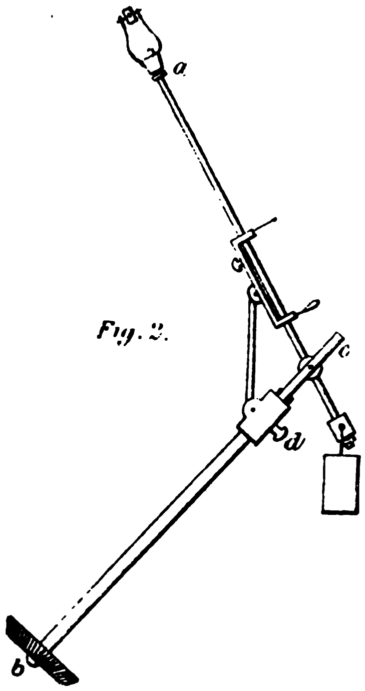

Fig. 2.

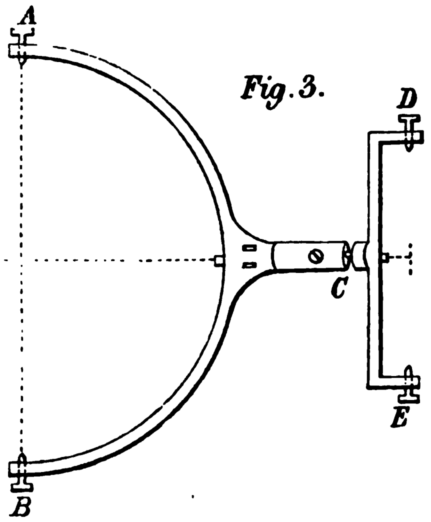

Fig. 3.

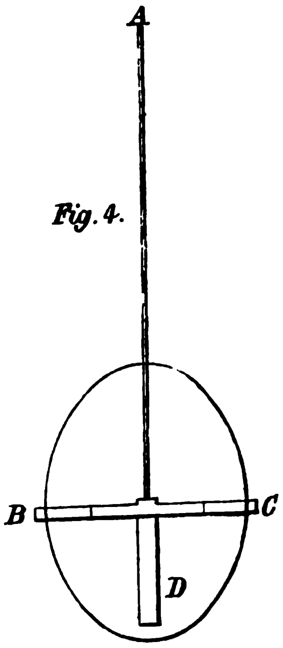

Fig. 4.

The larger of these is to be fixed quite tightly over the lower end of the polar axis, which is then to be passed through the pieces *b* and *c*, Fig. 1. Two little capstan-headed nuts are screwed finally over the upper end of the steel rod, one jamming on the other, and holding the polar axis so that it can turn easily without having endway motion. The piece *b* should now be temporarily cemented to the lower ring in the position shown in the figure, and the movable ring turned to a position at right angles to that shown in Fig. 1—that is, so that the two little projections *a a'* shall be at the extremities of what is destined to be an east and west diameter. Now, the position of the piece *b* on the rings should be shifted until a continuous small hole can be drilled through *a a'*, and the two sides of *c* at the centre of the parallelogram, while a rod passed through this hole should be bisected by the polar axis. This is the first important adjustment, and when this is satisfactorily arranged the piece *b* may be fastened to the under ring with screws.

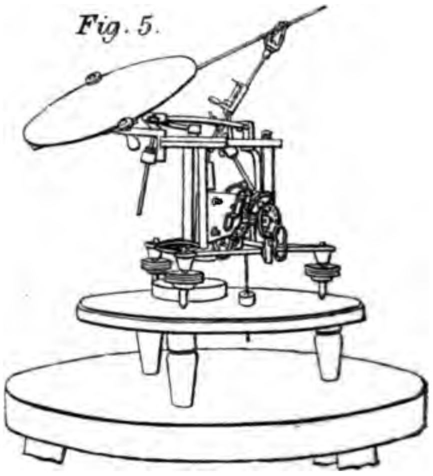

Fig. 5.

A. T. Hare.

(*To be continued.*)

TRANSFER OF THOUGHT.

[21889.]—It is a remarkable thing that a great many people will leave the real subject of a discussion in order to fasten upon some incidental detail, and attack an analogy rather than an argument, forgetting that in no case can an analogy be carried beyond a certain point, and that when it is carried further it becomes unmeaning. This is just what E. T. Scott (21858, p. 87) does when he asks me if I "mean to say that ether and chloroform have the same effect on us as mesmerism." I never said anything of the kind. I pointed out that precisely the same kind of objections as are now raised to thought transfer were urged against the possibility of a painless condition being produced. The argument raised by the medical men was that it was impossible that a serious surgical operation could be performed without pain to the subject: that argument was raised against the principle of possible painlessness; it was directed against mesmerism because it was only by mesmerism that it was claimed that the painless condition could be produced. My argument now is, that the discovery of ether and chloroform disproved the argument of impossibility, by proving that the painless condition was a real fact. Whether the action of ether and mesmerism is alike or not has nothing to do with the matter, except in so far that as no one knows *how* ether acts, those who know the fact have no right to deny the corresponding mesmeric fact because we cannot explain how it occurs. But this I do know, that ether and other anæsthetics act first upon the nerves of sensation, then upon the consciousness, and finally upon the great organic nervous system, and when this occurs the patient dies; but mesmerism never acts upon these latter, except by concentrating the vital energies upon them, and so enabling them to act fully and do their work. Hence the flurried feeble pulse becomes full and steady under mesmeric action, as I have often noticed.

Mr. W. J. Grey (21859, p. 87) complains of my "dogmatic tone." I believe dogmatism means the enforcement of an opinion by authority; now, I have not endeavoured to enforce an opinion at [illegible] who goes upon the stage and behind the scenes knows more of the play than he who sits in pit or gallery, and sees only the glamour and the lights.

As for "The Congregational Minister," I, having read the history of the "Cock-lane Ghost," the "Sisters Paterson," "The Davenport Brothers," (Dr.) Slade, the "Welsh Fasting Girl," and a host of other deceptions, should not remain satisfied with the performances of a young lady whose father kept always close to her as *an indispensable condition*. Let him test her in his own study alone, and by some surer tests than those afforded by such pitiful mountebank tricks as telling a card. Why, I have seen dogs and ponies do that, and have myself done some things that would perhaps astonish "The Congregational Minister."

It has been said, wisely or unwisely, that the world is composed of two sets, knaves and fools. Let us at least make an effort to avoid either category. **James Rhodes.**

TRANSFER OF THOUGHT.

[21891.]—I am glad to see by the remarks of "Sigma" in his letter 21856, page 87, that his objections are not directed against scientific inquiry into the "unknown." Surely, then, if "thought" is always accompanied by motion of brain matter, it is as much an "assumption" or "assertion" to say that this motion is caused by thought or mind as an "entity," using "brain" like a workman using his tools, as to conclude that the activity or motion of the brain, caused by impressions from without, produces thought or mind; since "Sigma" correctly observes the "how" of brainwork is not as yet definitely determined.

Having, therefore, two theories before us—viz., "Sigma" holding that "mind is an agent or entity producing motion in brain matter," Büchner, Haeckel, and others holding that "thought or mind is the result of motion in brain matter"—I prefer the latter theory, and hope "Sigma" will agree to differ from me. As to Solomon, I had no wish to quote "Ecclesiastes" in support of the German scientists, but simply to show that quotations from old writers may be produced as well in favour of materialistic views as against them.

Büchner says, in "Force and Matter," page 185:—"Now, in the same manner as the steam-engine produces motion, so does the organic complication of force-endowed materials produce in the animal body a sum of effects, so interwoven as to become a unit, and is then by us called spirit, soul, thought. The sum of these effects is nothing material. It can be perceived by our senses as little as any other simple force, such as magnetism, electricity, &c., merely by its manifestations." **F. W. H.**

[21892.]—"Sigma" and T. H. Carter have my most humble apologies, but my assurances notwithstanding that my opinions remain unchanged. T. H. Carter is a good way on the road to spiritualism, and similar delusions; "Sigma" has only recently started, but both talk exactly like thorough-going spiritualists when anyone plainly says he does not believe them. I cannot see any "gross impertinence" in assuming "fraud or trickery." An extensive acquaintance with ghost literature and the records of the marvellous has convinced me that, whatever may happen in the future, there never has been in the past a pretended miracle, apparition, or similar exhibition of the marvellous but someone played false—not infrequently the most innocent-looking party concerned. But I do *not* assume fraud or trickery From my own experience I know that men cannot long play these kinds of tricks without unconsciously becoming the victims of self-deception. I once tried table-turning with a friend of unimpeachable integrity. The table turned of course, and we both were convinced—the one that the other had turned it. My opinion now is we both did it.

When "Sigma" is expounding electric phenomena he relies on facts and experiments fearlessly; when he strays into the region of the marvellous we are invited, as by all seers, to take him—with a grain of salt. We are to start with an admission of his capability "of careful observation of facts, and that his opinions are *likely* to be more trustworthy, &c., &c." Begging his pardon again, we—or, at least, I—will do nothing of the kind, and if it is rude I really cannot help it. We part company on the threshold of investigation, and I hold him in exactly the same estimation as a respected lady of my acquaintance who, perfectly sane in all other respects, has two crazes: one that she will live to see the Day of Judgment; and the other that carrying an umbrella at any time is an act of superfluity, because no rain can ever fall on her. As wife, mother, and friend she is unexceptionable, so we appreciate her value and virtues, and keep as grave a face as possible when her delusions arise, remembering that each of us is more or less mad on some point. The "madness" of "Sigma," if it be such, may well be excused when we remember the vast benefits he has conferred on "Ours." Mr. T. H. Carter has as yet established no such claim on our consideration, and need not ride the high horse. **Kappa.**

[21893.]—I have been intensely interested in the discussion now going on in the columns of the "E. M." on the above subject. This week there appears (21864) a plain statement of facts respecting my little daughter Lilian. If required, this account could be supplemented by other statements of a like nature, enough to fill all the columns of your journal. These facts cannot be overlooked. It is impossible to explain them away, and I here publicly challenge "Kappa" (21836) or any living man to perform these feats by the aid of any code of signals, or any process of deception whatsoever. This child has been taught absolutely nothing to enable her to perform these feats, by myself nor anyone else. She would perform them equally as well for "Kappa," or any other person, in their own private drawing rooms, without any personal contact, and without the presence of myself or any of her relations or friends, who might be supposed to be accomplices. All that they would be required to do, would be to stand on one side and allow this little child, with *silent, unanswerable argument*, to teach them that there are more things in nature than the greatest thinkers have ever yet thought of. Only last week she taught one of those sceptics of the "Kappa" school, a lesson he said he should never forget as long as he lived. This child has been examined by men of science, eminent medical men, and others who lay claim to be something more than idiots to be imposed upon by such rididulous trickery as insinuated by "Kappa" and others of your correspondents. I believe every word written by T. H. Carter, "Sigma," &c., in their statements of simple facts that have come under their own observation. I advise Mr. Carter to persevere with the children he mentions. I believe he will find that they can perform these feats without contact. I wish particularly that he would try some of those, or similar, experiments he will find detailed in letter 21864. I, for one, should like to know the result. I may tell him that many others are deeply interested. Experiments with contact are always open to such charges as those of "Kappa," although the charges are utterly devoid of truth.

I have not the pleasure of knowing where "Kappa" resides; but if it were possible, I should be pleased to afford him an opportunity of witnessing some of these remarkable experiments, on condition that he would give to the readers of the "E.M." his opinions after he had seen them. I venture to say that his former letter would need a very great deal of revising.

I will not now trespass further upon your space. I will leave it to abler pens than mine to continue this interesting discussion, merely contenting myself with the part of witness, on the affirmative side of the question.

In conclusion, allow me to state that I dare undertake to say that this child would, if in a happy frame of mind, and surrounded by sympathetic persons, perform the following feat. If she succeeded (and she has already done so) I would be content to allow it to speak for itself.

Two entirely new packs of cards shall be produced, so that it could not be said they were in any way marked. One of these packs should be spread out face upwards on any table in four rows: one row for each suit, each row commencing with the ace, and ending with the king. This being done, the other duplicate pack (it need not be the same pattern at the back) shall be opened, and kept face downwards in the hands of any other person. That person shall draw out one card at a time, secretly look at it, and place it, always face downwards on the child's outstretched hand. She will then, in perfect silence, place it face downwards upon the duplicate card lying face upwards upon the table. She will thus continue till all the cards are paired. During the whole process the child can be effectively blindfolded. She will not only pair the cards in this inexplicable manner, but she will do it in a neat and exact way, as precisely as she could do it with her eyes at liberty. What has "Kappa" to say to this? **W. H. Bibby.**

Clayton Bridge, Manchester, Sept. 29.

HYDRAULIC RAMS.

[21894.]—Mr. Davies does not appear even now to recognise the self-contradictory figures that he gives as the result of the working of the ram. I will, therefore, work it out fully. I assume a cube foot of water to contain 6¼ gallons. Energy expended by the descending body of water is 22 cubic feet, weighing 1,375lb. falling 6ft., or 8,250 "foot-pounds." The work done is said to be 3 cubic feet, weighing 187½lb. raised 48ft., or 9,020 "foot-pounds"; that is to say, the work done exceeds the energy expended by 770 foot-pounds, and in addition to this there must be the energy expended in forcing the water through the pipes. I have always understood that the efficiency of a ram is only about ⅔ of the theoretical duty, which would reduce the delivery to about 1⅚ cube feet per minute.

On referring to Molesworth I find he says a ram will raise about one-fourteenth the quantity expended to a height of eight times the fall. This would make the quantity delivered $\frac{22}{14}$, or, rather over 1½ cubic foot per minute, which is even less than my estimate, and just half the quantity mentioned by Mr. Davies.

As Mr. Davies, of course, made his statement in perfect good faith, there is a serious mistake somewhere or other. Taking the figures as Mr. Davies gives them, the ram actually *gave out more work than was put into it*—a result I confess which I cannot reconcile with mechanical principles.

I notice Mr. Davies' quotation from a manufacturer's price list, in which I see nothing wrong, as the manufacturer does not give the *quantity of water expended* in raising the 300 to 4,000 gallons to a height equal to ten times the fall; so no comparison can be made.

The other queries in my former letter Mr. Davies has not replied to. Will he kindly do so? **A. S. L.**

[21895.]—Mr. P. J. Davies (letter 21870) asserts that by the expenditure of 22 cubic feet of water he can lift 3 cubic feet to eight times the height of the fall. Now, as 3 × 8 = 24, and 24 is greater than 22, the work done is clearly more than the power employed, notwithstanding the loss by friction and otherwise. If this be so, the problem of perpetual motion is solved, and water-rams will come into general use. **S. M. C.**

SYMBOLIC EXPRESSION OF FEET AND INCHES.

[21896.]—An "Assoc.M.Inst.C.E." fully confirms the stated advantages of simplicity and facility in writing possessed by the ordinary dash symbols.

Admitting, however, with Mr. Hopkins and "F.R.A.S.," that an alteration, either in the symbols used for minutes and seconds, divisions of the arc, or for the similar ones used for feet and inches, might be somewhat advantageous, the question, then, is whether the symbols for the former should not be altered in preference to those for the latter. Certainly the former have the right of the use of the dash symbols by reason of priority, but the latter are used to an infinitely greater extent. I accept as an improvement Mr. Hopkins's alterations to the symbols suggested by me. **B. H. Thwaite, Assoc.M.Inst.C.E.**

[21897.]—It seems now that Mr. B. J. Hopkins did not mean to advise the use of the symbols pi and delta for feet and inches, for he really prefers the latter (p. 67). What, then, was the reason of his letter? Mr. Hopkins objects to my objection to the use of delta for inches, that a similar objection would apply to the use of I for inch. If Mr. B. J. Hopkins will refer to my note again, he will see that I merely asked if ft. and in. *must* be discarded, why should not F and I do, instead of pi and delta? I have not suggested their use, but I can assure Mr. B. J. Hopkins that the risk of I appearing as 1 is very small, as in all my experience I never knew anyone write the figure 1 and the capital I in such a manner that there could be any doubt. With regard to the use of the apostrophe placed sideways, it is almost as objectionable as pi, for if the ordinary "stamp" is used it will involve "justification," and if special types are cast that will be two extra in an already crowded pair of cases. I wish your readers to understand that the use of any character not to be found in the usual pair of cases involves, first, the trouble the compositor has to go and fetch it; and, secondly, the great risk that it will never be returned to its proper "box." In a paper such as the "E. M.," all mathematical matter is usually put into the charge of one compositor, and he takes care to look after his "sorts"; but ft. and in. occur all over its pages, and if pi and delta are to be used, they will very soon run short. There is not the slightest objection to "Assoc. M.Inst.C.E.," using "minute marks" to indicate ft. and in., or anything else, if he will kindly append a "mem." to his copy that they are to be printed ft. and in.—that is when they are to appear in a paper like this. Another thing I may mention: Greek characters are usually kept in what I may term the "aliquot" founts; it would be a great nuisance for a printer to be compelled to keep Greek characters cast on every size type he may have in his office. **A Practical Printer.**

A Mr. Starbuck, agent for a railway at Portland, on the Pacific coast, required to send a quantity of iron rails and rolling stock to that place from one of the Eastern States. The freight by rail was estimated for him at £30,000. He obtained estimates for an iron sailing ship to take the goods round by sea, and found that it would be built for £25,000.

REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[51064.]—**Soldering.**—In reply to E. T. Scott's criticism, may I refer him to my two answers to this query, which, taken together, will not, I think, bear the construction he places upon them? I am quite well aware that oil is commonly used as a flux in soldering planished tin goods, on account of the required neatness of the finished work, but for most other metals soldering fluid is certainly better, and if this is applied to a greasy surface the result will probably be as described.—R. T. Lewis.

[51064.]—**Soldering.**—With reference to E. T. Scott's letter on page 91, I would observe that his use of the word "metal" is vague. He ought to have stated what particular metal he alludes to, because I take it that the *rationale* of soldering, also of welding and of brazing metals, is that first there must be surfaces free from oxidation or any foreign body which would prevent absolute contact; and then there must be a "flux," that is something which melts somewhat sooner than the metal which is to be melted, and thus protects it from the influence of the oxygen of the atmosphere. Thus it appears that these aforesaid methods of uniting metals could be effected in vacuo without the necessity for using any flux. Now, I have always found that tallow, which melts at a low temperature and is a suitable flux for lead, may, at a pinch be used also for tinned ware and even for copper; but for these two latter rosin is preferable. But as iron, steel, or brass requires a higher heat to solder, chloride of zinc is necessary. If to braze, a still higher heat, so borax comes into play, and to weld still higher, and sand containing silica is used, which covers the oxidating iron with a fluid glass. Grease would be burnt away at the heat required to solder iron; but I opine that R. T. Lewis allowed paraffin oil to come in contact with his work; even rubbing the copper bit with a smooth file that ever had any paraffin applied to it will make it extremely difficult to make a sound joint.—A., Liverpool.

[51203.]—**Music.**—On looking over some back numbers before sending them to the binders, I notice that I have omitted to reply to the request of "G. F. H." on page 559; but I do not know that I can add anything very material by way of "elucidating" what has already been stated. We are informed by works on harmony that consecutive octaves and fifths are very unpleasant, and, therefore, must not be used. My comment upon this was to call attention to the fact that consecutive progressions of all sorts, but more especially octaves and fifths, were constantly used on organs. When we play "full to fifteenth" (which is so useful a combination of stops that there is generally a composition pedal to control it) the principal and fifteenth give consecutive octaves with the foundation stops, and with each other; and the twelfth yields consecutive fifths with the principal and consecutive fourths with the fifteenth. All these progressions are forbidden by the rules, but the result of them (the progressions, not the rules), is very good. If we add the mixtures, we get a lot more of the objectionable intervals, and yet the result is exceedingly satisfactory. There seems to me, therefore, to be something wrong about the rules. I hope I have made my point clear to "G. F. H.," and must apologise for not having written sooner.—William John Grey, Elswick Science School.

[51313.]—**Power of a Wind Fan.**—I am sorry I did not see "T. P.'s" remarks on my query in time to write last week. I am sorry also I did not make myself sufficiently intelligible to elicit a reply at once. The reason was I wished to be as brief as possible, so as not to occupy too much space in the journal. Although I have not the pen of a ready writer, I will endeavour to be as explicit as possible in putting my question afresh, and I will put it hypothetically. Suppose I wish to fill a vessel with compressed air, and wish to use a *fan* instead of an *air-pump*, what compression could I obtain, stated in lbs. on a pressure gauge? The size and cost of a fan passing 200,000 cubic feet per hour, and whose is the best?—Ignoramus.

[51317.]—**Hand Punching Machine for Nuts.**—As I understand your querist now, he wants to punch the nuts out of sheet, not merely punch a hole through the nuts. I suppose it can be done, but I do not know of any machine for doing it by hand.—Essar.

[51346.]—**Clarionet.**—In reply to "Solus," I privately asked "Old Blow Hard" to contribute a few papers on the construction of clarionets, but I regret to say he has declined. Therefore I will now try to oblige "J. J. D.," and others interested, by sending all particulars as soon as I can, both for C and B flat Albert clarionets, although I would have wished it to come from a more competent source.—Vulcanite.

[51346.]—**Clarionet.**—"Solus" would like working drawings. These I am not able to give, or I would gladly oblige. I gave my mode of procedure on p. 68. I am not aware that the fittings, &c., can be bought ready made. Mine are made from German silver—wire for keys, pillars, &c., and plate for cups, rings, &c. Unless a C or an A clarionet is wanted for orchestral playing, I should advise you to make a B flat. When piano and clarionet play together, it is generally the case that the piano accompanies the clarionet, the clarionet part being written for B flat instrument, and needs no transposition.—Old Blow Hard.

[51346.]—**Clarionet.**—I find that I did not write what I meant in my letter on page 91, as I did not mean to express that "Vulcanite's" scale would make each hole at the same distance from its neighbour; but that it does make them in positions which are not those to be found in wind instruments (that is going in a regular mathematical progression), and to prove my position I append careful measurement of a C clarionet by Button and Co., of London, now in my hands, but unfortunately wanting the mouthpiece; these are taken from place where it is attached. (I may observe that as the reeds as purchased are $2\frac{1}{4}$in. long, it is not likely that the full bore is carried up to $1\frac{1}{4}$in. of tip, as stated by "Vulcanite" on same page.) I may also say that I am not aware that I recommended anyone to make clarionet's of spruce, but merely stated that it answered very well for experimenting on, and if left a little stouter than a boxwood one and French polished, looks just as well. Measurement of a "Button and Co., London," C clarionet:—Diam. of bore, $\frac{9}{16}$in.; total length from where the mouthpiece is attached to end of bell, $21\frac{1}{4}$in.; bell, $3\frac{3}{4}$in.; distance of first valve hole from where mouthpiece attaches, $2\frac{13}{16}$in.; second, $3\frac{13}{16}$in.; third, $4\frac{7}{16}$in.; thumb hole, $5\frac{11}{16}$in.; first finger hole, $6\frac{1}{4}$in.; second, $7\frac{1}{4}$in.; third, $8\frac{5}{16}$in.; fourth, $9\frac{3}{8}$in.; fifth, 11in.; sixth, $12\frac{1}{16}$in.; seventh, $13\frac{1}{4}$in.; first valve hole, $13\frac{13}{16}$in.; second, 15in.; third, $16\frac{9}{16}$in. This last remains open, unless the valve be pressed.—A., Liverpool.

[51431.]—**Legal—Slaughterhouse.**—The only way to put a stop to this nuisance is to take legal proceedings, and before doing that it would be advisable to consult a solicitor.—A Limb.

[51432.]—**Clarionet or Oboe.**—Have only now returned home from holiday tour, or would have replied earlier to queries of "P." and "E. T. S.," page 43. (1) I procure reeds (shaped only) through local music dealers: I think they order them from Lafleur's. I usually order three or four dozen at a time; never trouble myself about this or any other year's growth. I find that on an average 20 or 30 per cent. turn out serviceable; this satisfies me, as they are only 2d. each. If any appear very dry or brittle, I let them float for a quarter of an hour or so in lukewarm water, in addition to keeping them turning about in my mouth while getting silk and wax, &c., ready. I never now attempt to do anything with very narrow or light coloured reeds, but pitch them away at once as utterly useless for my purpose. I rarely fail to get a good soft drawing-room tone. Most undoubtedly the proper way is to get a regular fit out of reed-making plant, and so be in a position to carefully select and shape the cane for oneself; but this costs a lot of money, and I have never cared to incur the expense. (2) I can assure "E. T. S." that so far as I am concerned, oboe playing does not appear to have injured my health in any way. I know the instrument somehow bears an evil reputation, because when I first contemplated going in for it friends and well-wishers (?) foretold my early death by galloping consumption, and that my hair (what was left of it) would first turn grey, and then be brought with sorrow to the grave, &c., &c., and much more to the same effect, *ad nauseam*. However, here I am now at all events, as jolly as ever; I must, nevertheless, admit that in the early stages I frequently experienced a most unpleasant tight sensation round the head, with a disagreeable throbbing of the temples, unquestionably the result of too protracted blowing; but I have not felt such a thing for years, although, perhaps, occasionally blowing four hours at a stretch at musical evenings. I am unable to say whether the above killed Barry, or any other player; but I think that wind instruments, by no means confined to the oboe, might, with persons of peculiar physical conformity, &c., bring about death. As regards the small aperture of the staple permitting so little wind to pass in a given time, I am inclined to the opinion that just as much breath is expended in playing a piece on the oboe as on the soprano cornet. I am open to correction on satisfactory proof, but I shall stick to that opinion until I get the satisfactory proof. With respect to mastery of the reed, the time may vary between one month and ten years, or never. I know a gentleman, a most clever mathematician and linguist, who has never yet mastered the operation of cutting a slice off a loaf of bread. I don't know how long he would be struggling with an oboe reed, but would fix it, at a rough guess, at a little under a century. What the dickens "Vulcanite" means by the last four lines of his letter on page 69 I am utterly unable to comprehend; he has played oboe and clarionet alternately for the last dozen years, and yet says: "It (i.e., oboe) is done the same as an ordinary chemical blowpipe, &c., &c. I don't know which to pity most, the "alternately" or "the last dozen years." I never heard of the oboe being played from anything else than the throat and chest; in fact, the reed, from its very delicacy and skittishness, requires that large elastic reservoir of compressed air behind it for its proper performance, and any attempt (with me) to produce a note from the compression of the cheeks alone (if this is what the blowpipe allusion means) results in a short, coarse, "squaak," just like a squeaking toy animal. I really must shake my head and smile seriously at "Vulcanite"; but no offence, you know—all in good part.—O.

[51436.]—**Drainage.**—Your correspondent "An Inspector" should try the addition of plaster and coal oil to the cement he speaks of. But, in truth, the use of any cement at all shows the absurdity of the present blundering systems of drainage. Your correspondent should use iron pipes, and make his joints with lead in the usual way. If he should say that he never heard of drainpipes being made of iron, which is not unlikely, I can only say that he should make inquiry at Oxford, Westminster, Bagshot, Claremont, and other places where some sewage arrangements have been placed under the care of really competent engineers.—Nun. Dor.

[51439.]—**Photography on Wood.**—Premising that I know nothing practically about the matter, I may say that I believe the carbon process is used for the purpose, a tissue containing a maximum of colouring matter and a minimum of gelatine being selected by preference. Instruction and materials may be obtained from the Autotype Company. I have not heard of the powder process being used, and should doubt whether it would give clear enough impressions.—W. Robinson, Jun.

[51448.]—**Ebonising Cabinet.**—Almost as a matter of course, "Ignoramus" forgets to mention what wood he intends to use; but he will find plenty of recipes for ebonising in back numbers. The usual stuff is first deep staining with decoction of logwood, and then sulphate of iron solution. Add a little Prussian blue to the polish.—Nun. Dor.

[51450.]—**Glass Globes.**—I believe these glass globes are coloured by running into them, whilst still hot, a little amalgam of the colour required. For silver, I believe it is lead, tin, and bismuth 1oz. each, and quicksilver 4oz. Probably some of your readers can give more particulars.—Nun. Dor.

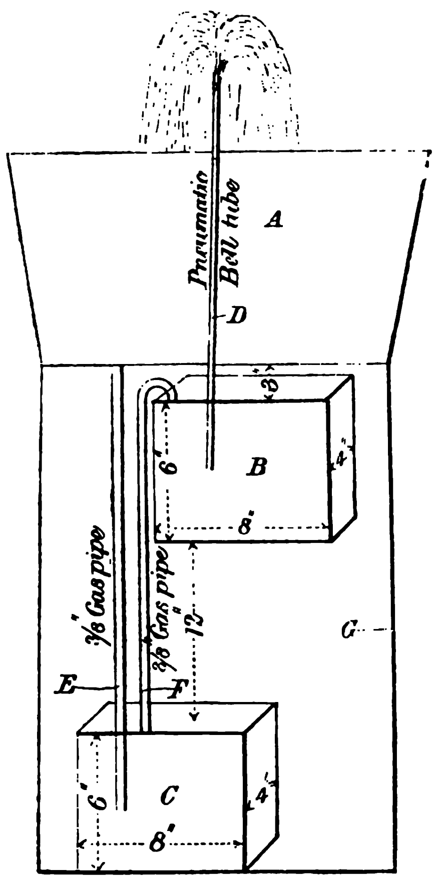
[51452.]—**Gelatine Emulsion for Slow Plates.**—Try the following:—Water 1oz., bromide of ammonium 10gr., nitrate of silver 15gr., gelatine 20 to 30gr. Take one-fourth the total quantity of water, dissolve in it the bromide of ammonium, and put the gelatine in to soak for an hour or so. Also dissolve the silver nitrate in another fourth of the water. Then melt the gelatine by putting the vessel containing it in a pan of boiling water, pour in the silver solution, keeping the mixture well stirred with a glass rod. Take out of the hot water and allow to set. Then break up and wash by any of the usual methods, dissolve, make up the bulk with water if sufficient has not been absorbed during the washing process, and coat your plates.—W. Robinson, Jun.

[51474.]—**Cuttings of Tinplate.**—Does not Mr. Milne know that several patents have been obtained for methods of utilising cuttings of tinplate? If he looks through the indices of back volumes, I am sure he will find a good deal of information on the subject; but any really profitable process is patented.—Nun. Dor.

[51491.]—**Hot-air Engine Patents.**—This query should have been sent to a patent agent, who, for a small fee would have supplied the querist with the information.—Nun. Dor.

[51557.]—**Nickel-Plating.**—If you use the sulphate, the proportion is $\frac{3}{4}$lb. to a gallon, if the nitrate, 9oz. to gallon. The bath should be of specific gravity of 7° Twaddle. I am sorry that I unintentionally misled you about the liquid bisulphite. I meant that you should prepare it at the time, as the solid does not keep, but is gradually converted into the sulphate. To prepare it, make a saturated solution of carbonate of soda, and pass a current of sulphurous acid gas through it until it reddens blue litmus paper. For a six-inch bichromate, zinc and carbon plates of about $2\frac{1}{2}$ to 3 inches surface. If they are kept going continuously all day, it is better to recharge them next day to the extent of emptying away the two liquids and adding fresh water and sulphuric acid. Of course you would keep a stock of crystals of bichromate in the carbon cell, which would not want renewing. It is better to use pure nitric acid; the red gas you notice is nitric oxide. It is better to crystallise and make sure of getting rid of all the acid used. The crystals are deliquescent and liquefy if left in the air. The dark colour may be caused by too rapid deposition or by an impure anode. You will find that the nickel will be deposited much better and whiter if you add a small quantity of boracic acid to the bath. In fact, an excellent solution is made by the sulphate and boracic acid alone.—E. A. H.

[51577.]—**Rushton's Self-Acting Fountain.**—I inclose sketch of a self-acting fountain, given me by a friend that has got one going very well; but I do not know if it is Rushton's or not. A is a cistern or tank to hold about one gallon of water; B and C are air-tight cisterns, 8in. by 6in. by 4in., with pipes soldered in, as shown in sketch; D is a piece of pneumatic bell tube; E and F are pieces of ⅜in. compo. gas tube; and G is a case or pedestal to contain the cisterns. The jet must be very small, or it will not work. To set it in motion, fill A with water till it charges C. The water then rises in F, and fills B about half-full; then blow in the jet to get a pressure of air in the top part of B. The air then forces the water up D and out of the jet, which falls into A; keep A about three-parts full. Hope this will suit "Chemicus." The pipes E and D must be kept about half-way from the top of B and C.—G. T. D.



[51580.]—**Model Boat and Incandescent Lamp.**—Trouvé's solution has been given, Vol. XXXVII., p. 180; it cannot be too well known, 3oz. bichromate of potash, 9oz., or, say, ½lb. sulphuric acid, and 1 pint water. If the bichromate is powdered, you may use 4oz. and 10oz. acid. It is most powerful when warm. The zinc must be amalgamated. A five-power lamp will require four to seven cells in series. The lamps do not all take the same current: it depends on the connections and thickness of the carbon filament. It is best to have plenty of power in the battery, otherwise the light soon becomes feeble. The smallest size plates I would advise are two carbons 6in. by 2¼in., and one zinc plate, 5in. by 2in. The zinc should be 1in. or more distant from each of the carbon plates, and if you mount a series of six sets on a sliding frame and use cells containing each one quart or three pints of solution, you will get a light equal, or, perhaps, a little better than a common mould candle; but you will find it satisfactory.—J. Sutcliffe.

[51592.]—**Utilising Vegetable Fibre.**—If "Nicaragua" will advertise name and address we shall be pleased to reply to his inquiry.—Death and Ellwood, 20, Bucklersbury, E.C.

[51630.]—**Organ Pipes.**—"G. R. T." (p. 45) wishes to make pipes for an organ with 1½ row, and of 8ft. tone. As it is to be of 5-octave compass, he should make the pipe for the lowest bass note C, 8ft. long, that is, if it is intended to be an *open pipe. If a stopped diapason is required, the pipe for this note should be about half the length,* viz., 4ft. If all open pipes are required, the second C from the bass should be 4ft. in length, and the third C 2ft., and so on in proportion with all the C's. The half row may be made a stopped wood pipe, if preferred to an open one. You can buy these pipes cheap enough, and so save the trouble of making them. This would be the most satisfactory plan to adopt if you have never made any pipes before, which, judging by the wording of the query, I should conclude you have not. By reference to back volumes you will find all the necessary information you will require with regard to the scale of the different pipes.—G. Fryer.

[51638.]—**Lathe.**—To W. W. Evers.—I have a friend that will do the boring and turning if I could inform him how to do them; therefore I should be obliged for particulars how to fit the head and tail stock up. My lathe head is for cone bearings and back gear. How are gear wheels, cone pulley, &c., made fast?—Miner.

[51639.]—**Gelatine, to keep.**—Various substances will be this—e.g. carbolic, salicylic, or glacial acetic acids. I do not know about restoring the elasticity, but it may be prevented becoming brittle by the addition of more or less glycerine or treacle.—W. Robinson, Jun.

[51646.]—**Straightening Fine-Gauge Bottling Wire.**—First get a steel plate with holes drilled through in a zigzag form—say, 13 holes, six on each side, forming two lines, leaving a distance between these lines for the wire to pass between two rows of iron pins, which must be driven into the holes; the wire to be pressed to the surface of the plate by a piece of leather; the whole to be fixed upon a block of wood. Secondly, get a wooden drum to rest the coil upon, and run the wire on through the pins to a large cylinder, say 4ft. wide. Cut the bow thus made right through, taking one end and cutting the whole into lengths as required. The straightening plates can be had of the writer.—James Mitchell, wire gauge and dressing-plate maker, High Roadwell, Halifax.

[51648.]—**Sensitising Linen.**—Float on a solution of gelatine or albumen containing about 10gr. per oz. of common salt, allow to dry, and sensitise by floating on a 60gr. solution of silver nitrate.—W. Robinson, Jun.

[51656.]—**G.W. Engines.**—The letter "S" painted on the engine lamps of this company means "Special"; that is to say, when the engine is drawing a special train, the lamp is turned so as to exibit the S; and when it draws an ordinary train, it exhibits a small white, diamond painted on the other side of the lamp. The two white diamonds painted on the buffer beams of engines signify that they are the property of this company; this being their "stock mark," with which most of their carriages and trucks are marked; as also are their signal levers, and I believe all their telegraph instruments.—Machina.

[51679.]—**Indiarubber Gaspipe.**—I have used a Fletcher table stove some years, and have bought his special tube, yet have never succeeded in avoiding smell from an uncovered tube. However, I have succeeded in covering a tube so that it has lasted free from smell 1¾ year, by giving it a good coat of hot glue, and lapping it with woollen braid while wet. I have tried two coats of copal varnish, but it does not answer as well as the glue.—Emeritus.

[51685.]—**Loose Teeth.**—In playing the flute there is no occasion for such violent pressure as you mention. W. S. Rockstro, one of the best authorities, says:—"The flute should be pressed firmly, but not violently, against the centre of the lower lip. It is most important that this pressure should be steadily and equally maintained. It should be just sufficient to keep the lip close against the teeth." I have played the flute (for amusement only) for the last 25 years, and my bottom teeth are as firm as ever. To harden the gums and keep the teeth in the best order, use only common salt for a dentifrice. After the first unpleasantness is got over, it is really surprising how refreshing it is, and what a healthy state of teeth and gums it causes.—J. E. A.

[51690.]—**Metaphysics.**—Your correspondent "F.R.A.S.," in reply to query, English Mech., Sept. 28, appears to hold an opinion with regard to the nature of metaphysics which could be of but little service to the inquirer whose question he undertakes to answer. I fear that neither of the books which he recommends would be of use to a serious student of philosophy, inasmuch as all four are written with the express purpose of showing that such a thing as philosophy (or that department of it which is termed metaphysics) has no existence. With regard to any positive philosophical view held by the writers of the works mentioned, it is quite indifferent as to whether "T. H." is enabled to contemplate "the larger circle, which includes both subject and object" (Lewes), or whether he adopts Huxley's alternation of materialism and subjective idealism; or, failing these, whether he feels himself called upon to agree with Bain and Comte, who do not trouble themselves with metaphysic at all. He will derive (if we except the pearls of fact which are strung upon these theories) about equal enlightenment from each. If, however, he should recognise, as he apparently does, the necessity for some kind of philosophy, and also that the explanations which constitute it should begin with a perfectly adequate and consistent theory of knowledge, there is no better book to begin with than Kant's "Critique of Pure Reason" (Bohn's ed.), to be read in conjunction with an exposition such as that of Prof. Adamson (David Douglas), or the larger work of Prof. Caird, of Glasgow. It would be beyond the limits of this reply to discuss the value of metaphysics in relation, not only to science, but to everyday life. The remark, however, may be made, that those who speak about "logomachy" in philosophy may possibly fail to remember that a similar phenomenon has exhibited itself in the early growth of every other science. Whatever wordy warfare over metaphysical problems may exist at present is quite probably due to the—self-constituted—friends of science, whose procedure, though based upon strictly inductive principles, generally involves them in metaphysical speculations of an extremely questionable nature.—Alfred Stapley.

[51694.]—**Lawn Tennis Court.**—I am greatly obliged to "K. W." and "Semper Fidelis" for their replies to my inquiry respecting the covering of concrete for a lawn tennis court. In reply to the latter, I cannot say what the intention of the owner was, who is now dead, and the property has twice changed hands. The idea of jagging up the concrete and covering with a fine layer appears to me what is required; but what material should it be composed of, that would only cost £15 for 4in. in depth, and would stand the weather.—H. B.

[51696.]—**Royal Arms.**—I do not think the courts will have much difficulty in deciding the question of intention to deceive. The very fact that a man uses the royal arms on his billheads or cards is impliedly an intention to deceive when he has no authority for their use. I have no doubt that the fine, when inflicted, will be very small—on the first conviction that is. As to those who have hundreds of pounds' worth of labels with the Royal Arms on, if they have any right to put them on there will be an end of the matter; if they have not, they will meet with their just deserts in being compelled to sacrifice them; for a tradesman who would be guilty of seeking to increase his business by leading the public to believe that he carries it on under royal patronage when such is not the fact, deserves no pity, but rather kicks.—N. E. Child.

[51698.]—**An Excellent Yeast.**—Take 4oz. hops, ½lb. brown sugar, 4qts. water, 2 tablespoons of salt, 1lb. best flour. On Monday, boil hops for 20 minutes, strain, and let rest to blood heat. Then mix sugar, salt, and flour in a pint of what is boiled, blend, and pour back into the water. Cover and put into a close place, or by the fireside. Mind, don't let the temperature be too high. Stir often during the day and always keep covered. On Wednesday add 3½lb. potatoes mashed up. Let all stand until Thursday evening, then bottle and secure the corks. My cook has dictated the above, and has used this yeast with the greatest success for the last five years. Should you not succeed in your first attempt, persevere—it is worth the labour. It makes excellent bread, and lasts as long as you care for. If "E. R. D." wants more information let him advertise his address.—Barley Bread.

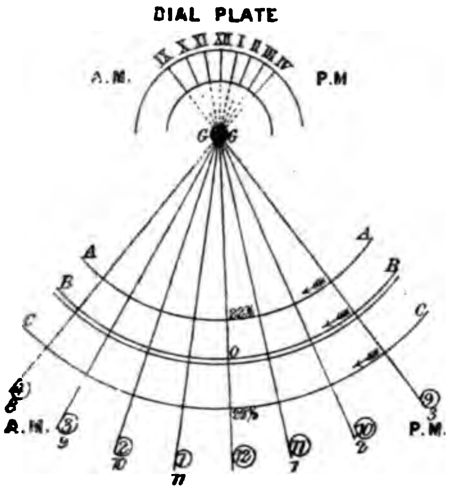
[51700.]—**Smoke Nuisance.**—The only way to prevent black smoke from issuing from chimney tops is by having sufficient grate area for the work to be done, so as to allow easy firing when side firing, or front and back alternate firing can be resorted to. There is a great difference found in different coals, furnaces, and men to put the coals on. What are the fires doing which "Garnet" inquires about? Are they steam boilers, furnaces, kilns, or are they pushed or working easy? If "Garnet" will advertise for a smoke-consuming apparatus, no doubt he will hear of about one hundred or more, but I have not yet met one which would entirely consume the smoke, which I think cannot be done in all-round practical working. If a good stoker has sufficient grate area he can prevent black smoke (which is a sure indication of waste), the smoke being of a light brown, and not approaching a nuisance.—Boswell.

[51700.]—**Smoke Nuisance.**—A great deal depends on the stoking; it is a bad plan to fire up on all the fires one after the other; much smoke may be prevented by firing alternately; also by putting the coals on in the front of the furnace, and when well alight, lightly push them to the bridge evenly with the rake upside down, so as not to disturb the under fire more than necessary; the dampers should be lowered a little when the coals are first put on till the coals blaze; this will frighten some stokers, who throw the coals on anyhow; the steam ought to be watched, and the coals put on when it is on the rise; but system is the main thing—that is, if the boilers are masters of the work they are doing. If "Garnet" will give me his address, I will give him a sketch of something that will prevent a lot of smoke. I have never seen a perfect smoke consumer: a lot of these so call "smoke consumers" are only so called.—Old NaCl.

[51701.]—**Levelling Slab.**—The querist must be under some misconception as to this, nothing of the sort being requisite for toning prints.—W. Robinson, Jun.

[51702.]—**The Herb Cure-All.**—The "vegetable" which "kind Providence has planted in our gardens," and which "The Kent Hermit" (p. 488, No. 957) says "will cure every known disease," and make the man of 75 as nimble on his pins as if he were only 17, is the herb Cure-All (*Atropa quackensis*), which can be found only by Unblushing Effrontery when accompanied by Inconceivable Ignorance.—N. E. Child.

[51705.]—**Sundial.**—The sun is in its June or north circuit at A A, in March and September at D D, and in its December or southern circuit at C C. G G is the gnomon of the sundial, placed in



any latitude north of the Equator. As the sun revolves from east to west, and uninterrupted by any clouds, it throws the shadow of the gnomon on the dial-plate, in the exactly opposite direction, no matter what the season of the year may be. In the June solstice, its speed per hour is 562½ miles; on the Equator, 900 miles; and in its December circuit, 1,237½ miles; so that the shadow on the gnomon never varies its direction, be the sun's speed what it may. The nearer to the northern centre the more complete is the circuit of the shadow on the dial-plate. And while in the December or southern circuit it only shows eight hours, in the June or northern circuit, it shows sixteen hours of the day in well-exposed situations. The principle of the sundial is the most simple of all instruments, and was probably the first philosophical instrument ever made by the hand of man. The motion of the sun is spiral or eccentric for 360 days, and concentric for 2½ days, or 60 hours, at each solstice. Its much slower progress in its northern circuits, of course, accounts for the greater heat we then experience. In the winter or southern orbits, its much greater rapidity of motion considerably reduces the temperature. If any impartial reader will only study the wonderful simplicity and extraordinary harmony of the sun's courses from east to west and from north to south, he will feel ashamed at the idea of a revolving earth and a motionless sun. There is much more to be said about it; and when public prejudice against it somewhat abates, I shall not feel I am trespassing on the indulgence of the Editor, as I do now.—John Hampden.

[51714.]—**Removing Ink.**—You can remove the ink completely by a strong solution of oxalic acid.—E. A. H.

[51714.]—**Removing Ink.**—The usual recipe for removing ink is a hot solution of oxalic acid, bleaching afterwards with a little weak solution of chloride of lime. As it is gelatine, you must try the acid cool. Crush it to powder, and put it on the part, then moisten with just warm water, and when the black colour is discharged wash off with cold water.—Nun. Dor.

[51715.]—**Fluorspar.**—Fluorspar is largely used as a flux in metallurgical operations. It is not used in the manufacture of glass; but its chief use is in the preparation of hydrofluoric acid for etching glass. It is easily tested (1) by heating it in the dark, when it emits a phosphorescent light, provided it has not been heated before; (2) by pounding some up and mixing with sulphuric acid in a leaden dish, placing a piece of glass over the dish as a cover, and heating, when the glass will be etched. If the substance is quartz, the sulphuric acid will have no action whatever on it.—E. A. H.

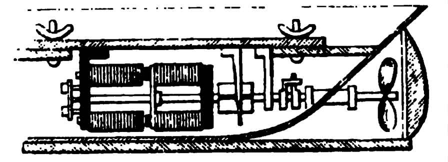
[51716.]—**Street Lighting.**—In answer to "Luminous," the principal regulating burners suitable for street lamps are:—Borrodaile's, 2s. 6d.; Peebles', 1s. 6d.; Snelgrove's, 1s. 3d.; Sugg's, 2s. 6d. These prices would be the ordinary governor burner; but if fitted with long necks about 6d. each extra. The sizes usually used are 4 or 5. The make of burner is a matter of choice and expense, there being practically little or no difference in their efficiency. With regard to reflectors, I cannot well recommend their use for street lamps, as they simply concentrate the light at the expense of distribution.—Gas Engineer.

[51718.]—**Outdoor Officers of Customs.**—All successful competitors for outdoor officerships in the Customs are admitted to the Service as Outdoor Officers of the *second* class, at a salary of £55, increasing to £80 by annual increments of £1 10s. They may be promoted at any time to the *first* class to a salary of £85, increasing to £100 by annual increment of £1 10s. No examination is necessary to get from the second to the first class.—L. E.

[51719.]—**Water Motors.**—The rule to calculate the quantity of water which will run through a borehole or pipe is as follows:—Let P = pressure in feet, d = diameter, l = length, and V velocity in feet per minute, then $V = 2837{\cdot}5 \sqrt{Pd} / l$, and $525\,V \times {\cdot}7854d^2$ = gallons of water per minute.—G. Worland.

[51720.]—**Electric Launch.**—Certainly, with pleasure. An electric launch 2ft. long. You have nothing to do but to reduce the dimensions given on p. 389, last volume, to the size required. Where do you propose to carry the battery and motor? It will not be easy to get them into the boat.—Nun. Dor.

[51720.]—**Electric Launch.**—A model 2ft. to 2ft. 6in. long should have 6in. to 7in. beam, the depth 4in., and be about 2½in. deep in the water. The hull can be made either in wood or tinplate, but it should not weigh more than 3lb., or else it will be too heavy to carry the engine and battery. In the drawing, the propeller shaft is passed through a tube in the stern; this tube has a stuffing box to prevent water entering. The engine shaft has a flat plate at the end with a pin fixed in it, which works the propeller by a wire catch. The engine itself is built on a baseboard fastened to the deck by two screws with wing nuts in order that it may be easily removed for adjustment. One of the electro-magnets shown revolves on the shaft; its poles are reversed by a split ring commutator, which is set close to the magnet. The other magnet is fastened to the baseboard; this magnet has a hole in which one end of the revolving shaft runs; the other end works through a brass bearing piece, which is also fixed to the baseboard. The magnets should be round iron $\frac{3}{16}$in. diameter, and the propeller may be 2in. or more. Two small Groves or bichromate cells should drive the engine. The battery is not shown; it should be placed in the fore part of the boat.—J. Sutcliffe.



[51722.]—**Prevention of Rust in Firearms.**—The following composition will keep firearms from rusting for months: Dissolve ½oz. of camphor in 1lb. of hog's lard; take off the scum, and mix as much blacklead as will give it an iron colour. Rub the steel all over with this, and leave it on for 24 hours, and then rub with a linen cloth.—E. A. H.

[51724.]—**Height of Barometer.**—29·76 in last line should read 29·74.—M.M.I.Sc.S.

[51724.]—**Height of Barometer.**—The barometrical readings as published in the newspapers are generally reduced to sea level, and a barometer falls $\frac{1}{10}$ of an inch for every 90ft. of elevation, so that when the *Telegraph* gives 30in., your aneroid should read 29·74in.—G. Worland.

[51728.]—**Photography.**—Rather too much nitric acid for so small a bath; formula otherwise all right. Smears probably owing to dirty plates, which should be "chemically" clean, not merely so in appearance. Cyanide of potassium will dissolve the image if proper care be not taken; but I never knew hypo. to do so.—W. Robinson, Jun.

[51732.]—**Crystoleum.**—A paste made of arrowroot is an excellent material for fixing the photo to glass. When you have fixed on the glass, at once proceed to scrape it with a flat piece of wood until all the air bubbles, lumps, and "snail marks" have disappeared. Then put it to dry, and when dry, rub as much of the paper off with sandpaper as you can. Then render it transparent by the following varnish. Canada balsam 2oz., turpentine 1oz., linseed oil 2oz. Let it soak thoroughly in for 24 hours, then wipe dry with a cloth, and then brush it over with spirit mastic varnish—made by dissolving 1oz. of gum mastic in 3oz. of turpentine—or else with copal varnish, and let it dry; and then it is ready for painting.—E. A. H.

[51733.]—**Retouching Negatives.**—Capital article on retouching and varnishing negatives in No. 853, p. 496. On. p. 366, No. 796, you will find an article thus headed, "Negative Retouching for Amateurs," which ought to supply you with all the information needed.—Nun. Dor.

[51734.]—**Scum Cock.**—The proper height for scum cock (?) (trough, I presume is meant) is at the working level. There are many kinds of troughs or collectors in boilers, several of which are patents. The one meeting most favour is the side trough (not a patent), which extends along one side of boiler; it is V-shape in section, the bottom being perforated, the perforations being passages from trough to pipe, which passes from boiler at front end generally, the front end being most convenient for use. Scum troughs are not generally put in new boilers now unless specially asked for, as they are considered of little use, except in special cases, such as a very light sediment forming, and they are always in the way of cleaning.—Boswell.

[51737.]—**Engineering.**—The colleges or institutions at which youths are grounded in engineering work are not intended to supersede the practice of serving five years or less in engineering shops, but are intended to prepare youths to learn more fully during their apprenticeship. The mere passing of a course at one of these institutions is of little value unless backed up by practical work. There is little change in the system pursued at the works of our largest railway companies: either a premium must be paid or the youth must work his way up step by step, unless he has other influence to help him. The best thing for "X. Y. Z." to do depends upon circumstances; but a youth not afraid to work with capital and influence at his back cannot help but succeed, and if he lacks any of these he will have to make the best of what he does possess.—G. Worland.

[51738.]—**Laundry Stove.**—One is as good as the other; if you regulate the draught with a damper just let sufficient air through to carry off the smoke after the fire is well alight.—Old NaCl.

[51741.]—**Fixing Pipes to Harmonium.**—The pipes can be fixed to the harmonium by glue, nails, or screws; but I am afraid that is not what your correspondent means. If our friend has a genuine harmonium by Alexandre, if he will take my advice he will let it alone, and not attempt to stick so much as one pipe on it. If he wanted to preserve carbonate of ammonia, would he steep it in sulphuric acid? The one is just as feasible as the other.—N. E. Child.

[51750.]—**Washing Negatives.**—No definite rule can be laid down, much depending upon circumstances; better, however, err on the safe side than find your negatives fading out—that is, if you want them to keep.—W. Robinson, Jun.

[51751.]—**Harmonograph.**—What you call the pendulograph is most likely the harmonograph or sympalmograph. See pp. 18, 93, Vol. XXV. Search the indices under those heads and "Lissajous' Figures." On the pages given there are illustrations of the apparatus.—N. E. Child.

[51753.]—**Sugar, Agent in Decolorising.**—Animal charcoal has the property of condensing or forming a loose combination with oxygen from the atmosphere, and in contact with the colouring matter it gives up this oxygen in a nascent condition, and so oxidises the colouring matter to colourless compounds.—E. A. H.

[51753.]—**Sugar, Agent in Decolorising.**—Watts, "Dictionary of Chemistry," p. 702, says that "Wood charcoal and animal charcoal have the power of forming insoluble compounds, especially with organic colouring matters. . . . The peculiar power of bone-black in removing colouring matters from solution is due to the more minute division of the charcoal, resulting from the interposition of the earthy matter."—R. A. R. Bennett.

[51756.]—**Cartridges for Martini-Henry.**—The powder used for loading these cartridges is, I believe, No. 5 or 6 grain; the charge 2½ drachms. About seven years ago, the charge was 3½ drachms; but it was reduced in order to lessen the recoil.—Machina.

[51756.]—**Cartridges for Martini-Henry.**—My best thanks are due to "Eccentric" and Mr. W. J. Grey. I have not used the black powder because I am told that the rifle "kicks" so heavily with it. If not troubling "Eccentric" too much, would he explain the mode of loading (I have the shells already capped). I do not understand what weight to use, whether troy or avoirdupois, having always been accustomed to measure powder for my shot gun in drachms: also about the wads, and where used, as a Government cartridge that I pulled to pieces had no wad under the ball, and are doubly patched.—Thos. H. Hall.

[51757.]—**Bradford's Washing Machinery.**—"Washerman" is somewhat severe on "One in a Fix." Possibly the latter has been "done" with his secondhand machine. If it is really Bradford's make, it will want very little repairing, unless, of course, it is totally worn out, or has been accidentally injured. If "One in a Fix" will advertise his address in "ours," I will do my best to assist him to put it right.—W. M.

[51767.]—**Continuous Brakes.**—The train that "Historian" saw at King's-cross was no doubt a District train; the brakes are a kind of Westinghouse, but I believe they are not automatic. There is only one brake, and until lately the pipes were coupled up, as on the Metropolitan trains. There is a valve at the end of each pipe, and when the pipes are connected the valves open, and when the pipes are unconnected the valves are closed.—T. M. R.

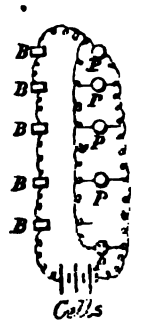
[51769.]—**Links in the Brake History.**—The first continuous brake (that is the first system intended to apply retarding force to each vehicle in the train) was invented by George Stephenson as long ago as 1832; it acted through the medium of the buffer-rods, and was put in operation as soon as the train received a check from steam being shut off and the tender hand-brake being applied. Some of the vehicles were fitted with brake-blocks to press against the wheels, others with sledge-brakes to press on the rails. After trials had been made on the Liverpool and Manchester, and Leicester and Swannington Railways, it was found that this brake could not act on the rear vehicles of trains, and it appears to have been abandoned in consequence of backing the train. The first steam brake was invented by Robert Stephenson. A patent was issued to him bearing date, at Westminster, 7th October, 1833, No. 6484, and was tried on the Liverpool and Manchester, and Leicester and Swannington Railways. It has always been understood that the object of this powerful *steam brake* was, in the first instance, to give the necessary "check" which was required to bring the *buffer-brake* into action. In reply to the third part of the question, the Westinghouse air-pressure brake was adopted first by the Pennsylvania Railroad, U.S.A., in 1869; it was not until 1872 that it was brought to this country. In the early part of the year 1872 the Caledonian Railway Company fitted a trial train with the air brake and signalling apparatus; on the 15th March it was put into daily working between Glasgow and Wemyss Bay. A very important official trial took place 28th March, 1872. Full details of the brake, and also the results obtained, were published in the English Mechanic at the time, Volume XV. page 295. A very good illustration of the engine (No. 101) as fitted with the brake is given in Dredge's "Pennsylvania Railroad." The Westinghouse automatic brake was invented 1871, tried in America in 1872, and first introduced into this country upon the Midland Railway. This company fitted it to a new train (consisting of engine and tender, No. 134, and fifteen vehicles), which was sent to the celebrated Newark Brake Trials, June 9th to 16th, 1875. At the conclusion of the trials this train was put into regular working between Bedford and London, from July 16th, 1875, to June 3rd, 1876. This became quite a "show train," as engineers from all parts of this country and the Continent rode in it to examine the working of the brake. The engine (134) was illustrated in the English Mechanic, Vol. XXVII. p. 190. I quite agree with your correspondent, "Historian," that certain links in the brake history deserve attention, and ought not to be lost. It will, therefore, give me great pleasure to furnish him with the notes I have taken at various trials, and other information in my possession.—Clement E. Stretton.

[51770.]—**Razor Paste.**—Levigated oxide of tin, prepared putty powder 1oz., powdered oxalic acid ¼oz., powdered gum 20gr.; make into a stiff paste with water, and spread evenly and thinly over strap. Take care to powder them very finely.—E. A. H.

[51778.]—**Steam Flour Mills.**—The power needed for a pair of stones depends, of course, on the quantity of feed passing through them. As a rule, they need 1·11 indicated horse power for every bushel ground per hour. At the mill I am at, our stones need about 18 indicated horse power for each pair.—Alpha.

[51779.]—**Metallic Precipitates.**—Bronze: Add hydrochloric acid, pass sulphuretted hydrogen, black pp. = copper, filtrate, reduce by zinc, dissolve in hydrochloric acid, add mercuric chloride, white pp. zinc; add ammonia and pass sulphuretted hydrogen, white precipitate. Copper is mentioned in the bronze.—W. D.

[51776.]—**Electric Bell.**—If you fit your bells up as shown in the sketch, your battery will not always be in circuit, and you will be able to ring them from any story.—W. D.



[51781.]—**Chemical.**—The ruby-coloured crystals you observe are a double sulphate of chronium and potassium, i.e., chrome alum. They are formed by the double decomposition of the potassium bichromate and the sulphuric acid. The reaction that takes place is: 1. On mixing bichromate solution with sulphuric acid

$$K_2Cr_2O_7 + H_2SO_4 = 2\,CrO_3 + K_2SO_4 + H_2O$$

and then the chromic acid oxidises the hydrogen, which is liberated at the zinc plate when the battery is working, and we get:

$$K_2SO_4 + 2CrO_3 + 3H_2SO_4 + 3H_2 = 6H_2O + 2KCr\,(SO_4)_2.$$

The $KCr\,(SO_4)_2$ being the crystals in question, i.e., chrome alum. The green crystals are chromate of zinc, formed by the action of the chromic acid on the zinc, on account of the liquids diffusing to a certain extent through the porous cell.—E. A. H.

[51785.]—**Electric Tell-Tale.**—In reply to "C. E." we have pleasure in informing him that we have made and supplied a special form of electric tell-tale to different asylums, which records in ink on paper the time the watchman or warder visits a certain station, how long he remained there, where he went to next, and how long he was in going there. One of these instruments has been at work for over two years in the North Riding Asylum, Clifton, near York; and its performance has been very flatteringly spoken of by the Commissioners in Lunacy, by whom it has been recommended.—Harrison, Cox-Walker, and Co.

[51788.]—**Compound Engine.**—If "Compound" will send to the "E.M." the initial pressure, point of cut-off in each cylinder, and number of revolutions per minute, and state whether condensing or not, I will try and help him. The way to get the number of square inches in a cylinder is to square the diameter, and multiply by the decimal number ·7854, which has been given numbers of times in the pages of the English Mechanic. But taking your cylinder, the areas will be 8 × 8 × ·7854 = 50·26in, 14 × 14 × ·7854 = 153·93in.—Fiber, Dewsbury.

[51792.]—**Cancer in the Mouth.**—What authority has "The Kent Hermit," for the statement that "smoking is frequently the cause of cancer in the throat"? I daresay that here and there some medical man with a "bee in his bonnet" would put the cancer down to smoking; but can the "Kent Hermit" find a jury of physicians and surgeons to endorse that dictum? The querist's friend is in all probability suffering from epithelioma, and he must seek the cause in something very different to smoking. Dewsbury is not a great distance from Leeds, and the sufferer should consult the surgeons at the Leeds General Infirmary. If he declines eleemosynary aid, he can consult one of them privately, or can subscribe to the funds of the institution.—Nun. Dor.

[51794.]—**Hardening Spindles.**—Pack them in a piece of iron pipe with animal charcoal, charred leather, hoof clippings, &c. (the first alone will do); heat to a red heat, and leave so for several hours; then turn out into water.—Nun. Dor.

[51794.]—**Hardening Spindles.**—"A. E. M." will find the best way of hardening above is to case-harden them with burnt leather thus: get iron case size he wants, burn some leather, old shoes, or anything he can lay hold of, to a cinder; then collect and crush fine, and put about an inch deep in the bottom of his case; then put spindles in layers, scattering burnt leather between every layer, covering top layer well up. Then put case in fire, heating gradually; let stop in fire about quarter of an hour after blood heat, taking care not to get to a white heat, then plunge out of case into cold water.—H. H.

[51795.]—**Sugar Boiling.**—The cause of your failure is simply this: you do not boil your sugar up to the height of temperature required. A thermometer, as used by sugar-boilers, would, I think, be a very useful instrument for your purpose. I do not know the exact price of them, but they are not very expensive, and with care will last a lifetime. I have seen a good deal done in this line; therefore, I have a good idea as to the cause of your failure.—G. Fryer.

[51800.]—**Measuring Hills.**—For measuring the altitude of hills, I have found a pocket aneroid barometer very useful and sufficiently accurate. You can buy them graduated for heights. Price, I believe, about £5 5s. 0d. Mine shows a difference of 10ft. Of course, if you know the altitude and the size of your tricycle wheel, with the number of revolutions, you can easily find the rate. This method is sufficiently accurate for the ordinary purposes of a pleasure trip.—F. G. A.

[51803.]—**The Portland Vase.**—Miss Meteyard says (p. 596, Vol. II., "Life of Joseph Wedgwood") that it is probable not more than fifty copies were made in Wedgwood's lifetime, and they were not all of an average degree of merit. Nor were they all exactly similar; some of the vases being "made with the white without any blue in it, and some with the yellow white, as different people have different tastes." Miss Meteyard, in a footnote, gives a list of 15 copies of the vase then known to exist. Fifty guineas was the price fixed by Wedgwood. I am afraid that your correspondent's copy is one of the "wholesale piracies" of Wedgwood's finest works, as it seems unlikely that Wedgwood would make smaller copies of the vase; at least, I see no reason why he should.—Nun. Dor.

[51803.]—**The Portland Vase.**—The following facts are gathered from "The Life of Joshua Wedgwood." In April, 1786, the collection of antiquities and articles of *virtu* belonging to the late Duchess of Portland were sold by Messrs. Skinner and Co. In this sale was included the "Barberini" vase, or Portland vase, as it was afterwards called. Wedgwood was determined to buy it at any cost, and bid up to upwards of a thousand pounds. At this stage the then Duke of Portland crossing the room to him asked his object in wishing to possess the vase. On learning the object the Duke offered, if Wedgwood would cease bidding and permit him to become purchaser, to place it in his hands and allow him to keep it sufficiently long to reproduce and do what he required. The copy was in due time produced, and as a *chef d'œuvre* of modern ceramic art, was perfectly unrivalled. Wedgwood produced fifty copies, which were subscribed for at fifty guineas each, but it is said that the sum thus realised (£2,500) fell far short of his actual outlay in making them. One of the first fifty is still in the possession of Mr. Francis Wedgwood, at Barlaston, another in the possession of Major Marjoribanks, at Guisachan, while the public have the opportunity of examining one in Mr. Mayer's museum at Liverpool. To the faithfulness and beauty of the copies of the Portland vase, Sir Joshua Reynolds, dating from "Leicester Fields," 15th June, 1790, said, "I have compared the copy of the Portland vase by Mr. Wedgwood with the original, and I can venture to declare it to be a correct and faithful imitation, both in regard to the general effect and the most minute details of the parts."—Melbourne.

[51810.]—**Cell.**—I must refer "Leo" to the "someone else," but would caution him to make sure that the said someone else's advice is sound. For my part I do not see how his requirements are to be met.—Sigma.

[51811.]—**Stains on Prints.**—The stains on your prints are probably caused by their being touched by fingers which have been dipped in the hypo. solution before they are placed in it to fix. Be careful also that when first put into the solution they are evenly immersed at once. Soft or distilled water should be used to make the fixing solution with, and remember never to lay the prints down on dirty boards or tables before or after fixing or toning.—Machina.

[51812.]—**Levelling.**—The column headed "Intermediate," as the name implies, is used for readings taken on uneven ground, or, whenever deemed necessary between the back and foresights.—G. Worland.

[51812.]—**Levelling.**—Intermediates are the staff readings taken off the main line, and by most surveyors, and also in Baker's "Surveying," no distinction is made between them and the foresights. The intermediate column is merely a matter of convenience, as by entering such sights in it, it keeps the main foresights separate, and the latter are, therefore, much more easily distinguished, and thus readily added up when checking the field book.—M. C.

[51812.]—**Levelling.**—A couple of pages of notes torn out of an old field-book will explain the use and advantage of the intermediate column better than pages of writing. All bench marks, and anything not on the line of chaining, and, in fact, everything except the backsight and fore-

19·18 rise			19·18 rise		65·86			

sight, go into that column, the result being that in the "checking" work at the bottom of the page you have only four backsights to add together, and four foresights, instead of 15 of each, as would have been the case had the two-column method been used. The column headed "chains" is generally used to contain the distances of the successive sights from each other; but when chaining the main line straight ahead, I generally enter the distances from the starting point in that column, though, strictly speaking, they ought to stand under "total distance." The book came from Waterlow's, where either kind is to be had. I greatly prefer the three-column plan, though I have often used the other for check levels where no intermediate sights are taken except a bench mark now and then.—J. K. P.

[51813.]—**Calculating Electric Light Leads.**—I do not much care about working out sums, and the practical questions put are not much in my way. But I have an article in preparation which will deal with the subject.—Sigma.

[51813.]—**Calculating E. L. Leads**—The only rule I know for calculating the size of wire for a certain current is to allow half a square millimetre for each ampère. Calculate thus: diameter^2 × (3·14)/4 = $\frac{\text{number of ampéres.}}{2}$ The E.M.F. does not enter into the question. To take your first figures, dynamo A gives 125 ampères. Required to know the diameter of wires which will carry such a current, $d^2 \times (3{\cdot}14/4) = 125/2 = {\cdot}785$ $d^2 = 125/2 = d^2 = 125/(2 \times {\cdot}785)$ = say 80—i.e., $d^2 = 80 \therefore d$ = nearly 9 millimetres. You can easily make this calculation for the other two examples yourself, 2 and 3. If you have an external R. of 12 ohms, it is quite certain you will not get 125 A. with 60 V.: you will get five only. However, suppose you have 60 V. and 125 A.; then you could arrange 50 lamps having 24 ohms R, and requiring 2½ A. in parallel, or 125 lamps of 60 ohms and requiring one ampère; B. 125 V., and 60 ampères. Suppose you have lamps requiring 1 ampère and having 25 ohms R., then you must arrange 5 in series and 60 parallel rows—i.e., 300 lamps. I hope this will fully explain the principle. F. G. A.

[51817.]—**Hygiene.**—For the study of this important subject, the following books may be read with advantage: "Practical Hygiene," by Dr. Parker; "Dwelling Houses, their Sanitary Arrangements," by Dr. Corfield; "Dictionary of Hygiene," by Dr. W. Blythe; "Sanitary Laws," by Lumley; "Factories and Workshops, their Sanitary Arrangements," B. H. Thwaite, C.E., see *Health* (weekly) edited by Dr. A. Wilson. The *Sanitary Record* and the *Building News* might be looked up with advantage.—Hygeinus.

[51818.]—**Battery for Coil.**—De la Rue's chloride of silver cell would probably suit. Its electromotive force is only about half that of the bichromate; but two cells could be used, and the resistance made sufficiently low by making the plates large enough.—J. Brown, Belfast.

[51826.]—**Vacuum Brakes on L. and N.W. Railway.**—Several of the main-line trains are now fitted throughout with the vacuum brake. Several engines of the following classes are fitted with the apparatus for working it:—Mr. Webb's "Precedents" and "Precursors," Mr. Ramsbottom's 7ft. 6in. singles and 6ft 6in. coupled expresses, and McConnel's "Large Bloomers." All Mr. Webb's compounds are fitted except "Experiment." All local trains are fitted with the chain brake, also the main line trains not yet fitted with the vacuum.—J. E. Spencer, Birmingham.

[51828.]—**Microscopic.**—There are some cats which have parasites instead of fleas; but I know not if the "caterpillars," described by P. Ward are their larva, as I have only the perfect creatures.—John Alex. Ollard, F.R.M.S., Enfield.

[51828.]—**Microscopical.**—If our young friend had pillboxed a lot of silkworms' eggs, I wonder if he would have expected to find, on opening the box, a lot of newborn moths? But, of course, in the case of such an intimate and everyday acquaintance as a flea, the existence of a larval condition is proclaimed to be a curious fact! If this incipient microscopist will place the next flea he finds on the stage of his instrument, he will perhaps be able to count that it has 9 segments in its abdomen, which, added to the head, and 3 in the thorax, make a total of 13; therefore it *is* a curious fact if his larvæ have only 9. As for the supposed spider's egg—well—?—Pulex.

[51828.]—**Microscopical.**—The eggs are, undoubtedly, those of the cat flea, and, inasmuch as fleas form no exception to the rule which obtains amongst the members of the insect world, when the eggs are hatched there emerge, not the perfect insects, but their larval forms. These, having passed through the usual stages of growth, in due course enter the pupa state, whence they afterwards emerge as perfect fleas. The eggs are of elongated form, and their pearly iridescence makes them pretty objects under the microscope when properly illuminated. When new laid, their slightly viscid surface causes them to adhere to the cat's fur, from which they are afterwards detached in large numbers by the animal's movements. If kept warm they will hatch in a few days, the larvæ being white, without eyes or legs, but having two small antennæ, numerous spiny hairs, and two small hooklets at the tail. There are commonly 13 segments, not nine, as stated by the querist. Eggs corked in a small glass test-tube, with a little loose wool from a blanket, will hatch freely if carried in the pocket for a few days, and with care and proper feeding the whole of the metamorphoses of the brood may be observed. When first hatched the larvæ will feed voraciously upon dried human blood, but it is not easy to rear them on this diet; blood which has been previously digested by the flea appears, however, to be their natural food, and on this they live and thrive. A supply of this aliment may be insured by keeping two or three fleas in the same tube, and allowing these to feed upon your arm *ad libitum*, at intervals.—R. T. Lewis.

[51830.]—**Photographer.**—"Amateur Tyro" should get two planed pieces of inch deal board, and lay the prints he wishes to wash one upon another carefully between several thicknesses of blotting paper, which place between the two boards; press in a screw press or by heavy weights; this will squeeze nearly all the water out of the points, then immerse them again in water, where they will soon separate from one another, and the process can be repeated several times. This is a most effective way of washing prints when water is scarce. Care should be taken not to underfix prints. Many stains arise from insufficient hypo.—Hayling Island.

[51830.]—**Photographer.**—I do not know of any way for removing "hypo." from negatives or prints but by constant washing. You should get up a cistern—a barrel would do first-class—which you could fill as often as necessary. You could have a tap at the bottom of your barrel cistern, and under this you can place your negatives, and allow a stream of water to flow gently on them, say, for a quarter of an hour or so. Then let them remain in clean water over night, and wash under stream again in the morning. Do not use any reagents to remove "hypo.," as they have also the tendency to weaken the image. This is the plan I have adopted under almost the same circumstances as those you mention.—W. Fawcette Gilcriest.

[51833.]—**Drawing-Room Screen.**—First make your frames, procure enough Drogheda linen (unbleached), and tack it tightly on, then coat with size; when dry cover this with what is known to paperhangers as lining paper (this sort shrinks as it dries); stick this as well as the pictures with very thick paste with a little glue and alum mixed in it, and you will make a good job of it, as I have done.—A., Liverpool.

[51835.]—**Contact Breaker.**—The rapidity of vibration might be reduced by connecting to the armature a piston working in a cylinder closed at one end, except a small hole for gradual escape of air as the piston rises or falls. By arranging a proper size of hole, the required speed can be given, provided, of course, the magnet is sufficiently powerful to work against this resistance. Or, if the speed is not to be much reduced, perhaps the addition of a flat plate to the armature would, by acting against the air, offer sufficient resistance to its motion.—J. Brown, Belfast.

[51837.]—**Compressed or Liquefied Gases.**—All the gases have now been liquefied. Many were reduced for the first time by Faraday. Andrews made most interesting and valuable researches on their boiling points, &c. Accounts of the work of both may be found in the *Proceedings* of the Royal Society. Oxygen and hydrogen were the last to yield to Cailletet in France and Pictet at Geneva only a few years ago. An account of the apparatus employed by the latter appeared in the English Mechanic at the time. I do not know of any book specially treating of the subject.—J. Brown, Belfast.

[51841.]—**To Mr. Wetherfield.**—The law existing at the Cape of Good Hope is the old Roman law. There is a special institution there which administers to estates and acts as executor. It is very popular in the colony, and bears a high character. A few years ago I was concerned for a large estate, a part of which had to be realised at the Cape, and this institution acted as executors of the deceased gentleman for the property there. The papers are now out of my hands, and I cannot give the exact name and address of it. It may be found in the "Cape Directory," at Street's, Cornhill.—J. D.

[51846.]—**Hyposulphite of Soda.**—It is far better to use a fresh solution for clearing negatives, and not the one you have already used for fixing prints. When the same hypo. solution is used too long, it gives off fumes of sulphur, which will cause any print or negative placed in it to ultimately fade.—Machina.

[51847.]—**Small Dynamo Working Induction Coil.**—A dynamo will work a coil very well if care be taken that the primary is not spoiled or insulation broken down by too much current. The late Mr. Spottiswoode found that if the brake be removed or screwed down, and an alternating current sent through the primary, a very peculiar, thick, and apparently continuous, discharge is obtained at the terminals.—J. Brown, Belfast.

[51849.]—**Commutator.**—On the axis of the armature, but insulated from it, secure two half-cylinders of metal, each connected to one end of the wires. Arrange two springs at opposite sides of the axis, so that one always presses on one of the half-cylinders. The position of the several parts is to be so adjusted that the spring passes from one metal to the other at the moment in which change of diversion of current takes place in the wire, then one of the springs will always be + because it is connected to that end of the wire which the magnetic actions render the positive end.—Sigma.

[51852.]—**Gazogenes.**—In reply to "Beta," the escape of gas is occasioned by the worn out condition of the indiarubber washer, which is fixed in a groove between the movable head and the collar. I have repaired mine by simply taking out the old ring and cutting out an indiarubber ring about a ¼in. thick, and putting in the place of the old one; but I would mention that when screwing on the head it is as well to use a little grease, as it is the friction caused by tightly screwing that destroyed the old washer.—No. 23.

·[51853.]—**Electric Lighting.**—The number of lamps must be equal in each of several series so as to make the resistance of each series equal. If this were not so (say if one series had three lamps, and another five), the current would rush through the three, and probably destroy them, while the other row would be only partially illuminated. The number in series, and also the number of series, has to be adjusted to the E.M.F. and internal resistance of the dynamo.—Sigma.

[51853.]—**Electric Lighting.**—"Veber" seems to have missed the point. Incandescent lamps must be arranged according to the current they require, and according to the machine feeding them. Thus, suppose I have a dynamo giving ampères at 40 volts; my lamps require 1 ampère each and their resistance is 40 ohms. Then I arrange all my lamps (60) parallel; but, suppose my machine gives 400 volts and only 6 ampères, then I arrange 10 in series and 6 parallel rows—i.e., 60 lamps. Perhaps you would like to read the latter part of my reply to question, No. 51813.—F. G. A.

[51854.]—**Legal.**—After signing such a covenant as you mention, you cannot, nor dare you, engage in or carry on any such business, either wholesale or retail. The covenant might even go farther than you imagine, as this clause of it is a very binding one.—W. Fawcette Gilcriest.

[51856.]—**Ozone Papers.**—I think the following (given in Cooley's "Encyclopædia") would answer your purpose better than ozone papers and with less trouble:—"Linden has suggested an easy method for producing ozone for hygienic purposes. Make a mixture of manganese peroxide, potassium permanganate, and oxalic acid. Two spoonfuls of this powder, if placed on a dish and moistened gradually with water, will generate sufficient ozone for an ordinary sized room. More water should be added when the evolution ceases. The powder may be kept in a bottle ready for use." The quantities are not given, so I suppose it does not matter what proportions are used.—R. A. R. Bennett.

[51857.]—**Mushroom Bed.**—These may be made if you have a cellar or outhouse where the temperature will not fall below 45° nor rise higher than 70° Fahrenheit (light not necessary). Make an upright boarding 30in. high from floor, and about 3ft. wide from wall. Take a quantity of fresh horse manure about 4in. deep, beat hard with a mallet, at intervals put in more and continue to beat firm till you have it about 18in deep. Now let it heat, and when the heat is on the decline and about the warmth of new milk (test this by putting in a few hard wood sticks), break your spawn (which you may get in bricks of any seedsman) into pieces about the size of a hen's egg, and put about 2in. below the surface and about a foot apart all over the bed, beat hard down, if good the spawn will soon spread in the form of filmy threads, then put on about 3in. of fine soil, again beat firm, and if the bed seems dry give a very little water. You must now wait some six weeks for your success. If it is a light cellar spread a little straw loosely over the bed. If not successful try again, as mushrooms are very eccentric in their growth. The above is a plan adopted in many gentlemen's establishments.—D.W.W.

[51862.]—**Radiant Heat into Light.**—If radiant heat be concentrated by a lens or concave mirror on a suitable incombustible substance, the latter may be raised to incandescence, thus emitting light. Radiant heat might raise steam to drive an engine to drive a dynamo to produce the electric light; or we might put it like the children's rhyme: This is the radiant heat of the sun, that raised the water that made the rain, that fell in the stream, that drove the mill, that turned the grindstone, that gave a spark that emitted the light that "P." wanted.—J. Brown, Belfast.

[51863.]—**Arranging Brass Band Music.**—The following arrangement will no doubt be found suitable to the querist:—1 soprano, 8 cornets, 2 altos, 3 valve trombones, two in B flat and the other in G; 4 E flat tenors, 1 B flat baritone, 2 euphoniums, 1 bombardon, 1 bass drum, and also 1 side drum, making in all 24 instruments for the same number of performers. The querist can, of course, make any alteration to this that he thinks more suitable to his requirements.—G. Fryer.

[51864.]—**Indicator Diagram.**—This is a similar case to one I had to examine last week. This engine had a 5ft. stroke, 70 rev., and 17in. diameter of cylinder. It was the high-pressure cylinder of a compound engine of 50 nominal horse power, made by a firm of high repute. On examining the main valve, I found the steam ports to be 7¼ × 1⅞in., this gives an area of 13¼ sq. in., but in centre of port there was a block (for valve spindle to pass through) 3½ × 1⅞; and this, subtracted, leaves scarcely 7¼ sq. in. actual area, or area of steam-port equals $\frac{1}{32}$ that of cylinder, when they should be at least as 1 : 12. The above clearly proves that whilst engine-makers pay more attention to the proportioning of steamways, so sure must wire-drawing continue. In your case, you should have sufficient lap and lead on main valve for it to cut off at ¾ the stroke; then place back slide-valves eccentric opposite the crank, and attend to the exhaust, which is now too late, both in the opening and closing. Indeed, the exhaust does not open wide enough for the free exhaustion of the steam. Having seen to the above, you will have done all that you can do in this direction.—Engineer, Dewsbury.

[51869.]—**Ozone.**—The following is from Bloxam's "Chemistry" (page 56):—The water the bottle is found to contain, besides the phosphorus and phosphoric acid formed by the slow oxidation of the phosphorus, some hydric peroxide, whence it has been sur [illegible] the formation of ozone is due to the decomposition of a molecule of oxygen into electro-negative oxygen, which combines with another molecule of oxygen to form ozone, and electro-positive oxygen which combines with a molecule of hydrogen to form hydric peroxide thus—

$$O_2 + \overset{-}{O}\overset{+}{O} + H_2O = H_2O\overset{+}{O} + O_2\overset{-}{O}$$

This view is supported by the circumstance that hydric peroxide is produced in every case when ozone is formed in the presence of water.—R. A. R. Bennett.

[51871.]—**Keel for Model.**—The method I have adopted is to make a mould by tacking pieces of wood on a board of suitable length, breadth, and thickness for the proposed keel, of course allowing for planing it all over when cast, with an iron-soled plane, having the iron set at an acute angle. (Memo: Stir your lead with a tallow candle, and skim with a bit of deal wood before pouring, to get a sound casting). Fasten by means of screws from the inside, drilling holes (very loose and screws well greased) in the lead.—A., Liverpool.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list and send what information they can for the benefit of their fellow contributors.

Sleeping with the Head Northwards.—M. G. de Rocquigny writes as follows to M. l'Abbé Moigno, editor of *Les Mondes* on this subject:—"M. C. Vignier wrote as follows in the *Revue Philosophique* for 1882, No. 7, July, p. 31.: 'Is there, then, an agency capable of exercising a continuous action on the apparata of the nerves (*canaux*), varying with the position of the head? To my mind this agency exists, and is none other than terrestrial magnetism. That an all-pervading force should be without any action on our organism when we see it influenced by the least variation of light and heat is surprising enough already. But it is beyond dispute that galvanic currents not only exercise a powerful effect on our nervous system, but that electro-magnets themselves produce well marked effects in certain nervous affections. The experiments undertaken at Salpetrière by M. Charcot leave no room for doubt on this point; and there must be some foundation for the practice adopted by the Swedish peasants, who cause themselves to be buried for several hours so as to lie north and south in order to cure neuralgia.' To this the author adds the note:—'I have this fact from M. Nordstrom, Swedish Consul at Alger. It is, moreover, sufficiently proved by physiological experiments that a very close relation exists between the nervous system and electricity, of which magnetism is but one form. In another note the author quotes the following experiment, carried out by M. Ziégler, of which, M. Vogt was a witness:—'M. Ziégler takes a lens of soft iron, he exposes it in a place where it will receive the lines of terrestrial magnetism and redirect them on to the organ to be studied. By thus projecting the magnetic lines concentrated in this manner on the heart of a rabbit, the rhythm of the heart is changed; if the lines are concentrated on the intestine, violent peristaltic movements (*péristaltiques*) are caused (*Journal Officiel*, May 18, 1881). The preceding facts will, perhaps, appear to you, Monsieur l'Abbé, to add some degree of probability to the theory put forward by *The Electrician* of London.'"

QUERIES.

[51872.]—**Bees.**—Will some one answer the following queries, viz.: (1) Why not transfer bees after September or before April? (2) What is the best time for introducing Ligurian or other queens to an alien stock? Would not this be a good time to introduce them to drummed or condemned bees? It would be so easy to find the queen. (3) Could I get them in Ireland and at what price? (4) What do bees do with the honey they consume when smoked? Do they put it back again? (5) Suppose a hive 15lb. weight, gets 15lb. of syrup, say, in a month, will they store it up just as they get it or convert it into honey first? (6) What is the object of putting vinegar in the syrup for bees? Is it to destroy the grain of the sugar? If so, would not cream of tartar be better? (7) Some of the foundation in my bars sagged so much that one side there was scarcely room for any cells, and at other side they were made nearly twice the ordinary extent. Whether the eggs laid in extra sized cells will bring out bees the same size as the small ones? (8) What is the best wood for making bars for a frame hive? (9) Would some of the readers of "E.M." who have been out in Manitoba, kindly say whether it is a good place for bees, whether it is hard to get them there, and what kind thrive best?—F.

[51873.]—**Fir and Deal in Specifications.**—Under head of Carpenter and Joiner I read "all fir to be best crown Memel," and "the deals or battens to be Christiania, Archangel, or Petersburg." What I want to ask is: Why should all fir be best crown Memel, and why should all deals and battens be Christiania, Archangel, or Petersburg? What is the difference between Memel, and Christiania, Archangel, or Petersburg?—J. Corson.

[51874.]—**Stone in Specification.**—What does a "tooled bed stone" for a column to rest on mean? And why are bedstones under girders described as "tooled stone templates under ends of girders with boasted beds."—J. Corson.

[51875.]—**Starch and Gluten in Flour and Wheat.**—I should be exceedingly obliged if any chemist could give a simple means of getting the approximate quantity of starch and gluten in flour or wheat.—W. S.

[51876.]—**Calls for Birds.**—Will some of your readers kindly explain how to make a whistle or call for plover, partridge, &c.—F.

[51877.]—**Telephone for 140 Miles.**—To Mr. Lancaster or Mr. Tolman.—Will you kindly give me a few hints as to the most suitable proportions for an induction coil for a telephone trensmitter to work on a line of 140 miles using a Bell receiver? What I wish particulary to know is: (1) Length and diameter of core, size and number of layers of primary wire. (2) Size of secondary wire, also quantity of the same either by weight or number of layers. (3) Is there any rule by which I may know how many Fuller's mercury bichromate cells I require to operate the call bells on a line of, say, 10 to 20 miles, using the line current to ring bells, line wire No. 8, galvanised iron. Will you also give your opinion on the following plan for operating the call bell on line of 140 miles. I propose to send current from the line through a vertical galvanometer. On the spindle carrying the astatic needles, is a piece of thin sheet platinum, which, when the needles are deflected, will press upon another piece of platinum and put the bell coil in circuit with the local battery. Will this do? Or, would a relay be better? Please to give resistance of coils for whichever you think best. Replies to the above as explicit as possible, will much oblige—New Zealand Telephone.

[51878.]—**Electrical Attachment to Organ Keyboard.**—I have an idea of fitting up an electrical keyboard for organ as follows:—An electro magnet to be placed under each pallet with armature fixed to pallet wires, to be conveyed thence to keyboard, to be placed at a distance of, say, 30ft. from organ. The effect would be, that upon depression of each key in playing, a circuit would be completed, which, through the magnet and armature, would attract each pallet and so emit sound in the usual way. Would any of our correspondents kindly offer me some advice, together with information as to form of battery best suited to the purpose, with sizes of wires and magnets, or please suggest any better method, as this is simply my own idea? Any hints will be thankfully received by—New Subscriber.

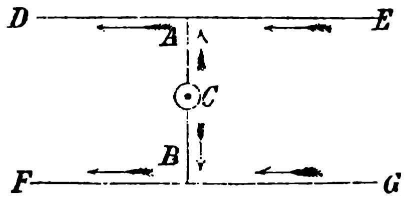
[51879.]—**Locomotives.**—Can any of the readers of the "E. M." kindly inform me whether the "dimensions of locomotives" given on pages 506—517 of Molesworth's "Pocket Book," are taken from engines now running?—and if so, to what lines do they belong?—St. Aubyns.

[51880.]—**Pressure on Screw Propeller.**—Will some of ours kindly give the rule for finding the pressure per square inch on a screw propeller? Suppose the engines indicated 300 horse-power, and we deduct 25 per cent. for friction, &c., the propeller 12ft. diameter, with four blades, each blade 10 square feet of surface, or area. What will be the pressure per square inch on the four blades?—Screw Shaft.

[51881.]—**Gas-Making Apparatus.**—Can any of your readers inform me about what would be the cost of, and fixing a plant for a small works in the country, consuming, say, from four to five hundred thousand cubic feet per annum? Also the comparative cost of gas made from coal at 8s. a ton, and from shale oil? How much fuel would be required to produce 1,000ft. of gas? Any information relating to the above will be thankfully received.—J. P. Seddon.

[51882.]—**Engine Query.**—Can any correspondent tell me the advantage of inside and outside cylinders for locomotives, as there appears to be some advantage in both?—Ingenieur.

[51883.]—**Electro-Dynamics.**—Can "Sigma," or any other of our electrical friends, explain the following, as I am evidently at fault somewhere. A B is a horizontal wire capable of turning on a vertical axis C, the electric current ascending by it and moving outwards as shown; the lines, D E, and F G, representing the magnetic currents of the earth circulating from east and west. According to Ganot's "Physics," the wire A B ought to rotate from east to west. Now I can't understand how this can take place, for, by Ampère's law of angular currents, the half A of the wire A B would move in the direction E, and the other portion B towards



G, so that two equal and contrary forces would be acting on the wire A B, and therefore no movement could take place. An explanation of the above would greatly oblige an—Anglo-Australian.

[51884.]—**Gravel from River.**—To Mr. F. Wetherfield, or "Lex."—On one side of a tidal river the land is in the hands of a landed proprietor, who holds title to a "several fishery" on the river. On other side land is in possession of an other person, who claims as far as his land runs, to have a right to half the river for the purpose of fishing, and also to lift gravel, sand, and stones from the bed of same. The landed proprietor denies this right to the gravel, &c. Has he the law on his side? If it be decided that he is only entitled to claim half the river, where is the dividing line to be drawn? Midway between the banks, as filled by the tide, or middle of the stream when the tide is out? It is only then that the gravel, &c., is laid bare and can be secured. There is a public right of way into bed of river. Can the man who does not hold the fishery send his carts by this way into the river, cross over to his own side or half of river, and take away sand and gravel from there, without rendering himself liable for trespass? It was stated in a former reply, when somehow the query was wrongly printed—"general" being printed instead of "several"—that the sand, &c., all round coast belonged to the Queen.—Justitia.

[51885.]—**Wages.** — To Mr. F. Wetherfield or "Lex."—A ploughman is engaged at so much per week, with free house and ¼ acre of potato ground which he is to seed and manure for himself, as part of his wages. By subsequent agreement, in writing but not stamped, he engaged to give three months' notice before giving up his service and in May he gives notice that he will leave in August. This he does and enters the service of another, giving up possession of the house, but holding the land, as the crop is not ready for lifting. As he received the ground as part of his wages, when he leaves his first service and enters another, can he still claim the free use of the ground till it is convenient to him to remove his crop? If not, what remedy has his first master, supposing he does not wish to have to buy or give compensation for the crop, but only to get compensation for use of his ground by a man who being no longer in his employ, ought not to be entitled to get wages from him while he is working for another? Man entered on service in January. What rent or portion of rent is master entitled to deduct from balance of wages still in his hands? Supposing him to have left immediately after putting crop into ground in April, would he not be entitled to pay the whole con acre rent like any other man?—Diago.

[51886.]—**Wimshurst Influence Machine.**—I am about to build a Wimshurst machine, with 16in. plates and should feel obliged if any reader could give me the following information. (1) How many sectors should I need, what length and width, and how can I fasten them to the glass? (2) How can I fasten the plates to the wooden bosses? (3) Would a metal spindle answer instead of wood or ebonite? (4) What varnish must I use for the plates? (5) Would the rod that carries the wire brushes do if screwed on to the framework over the ends of spindle? (6) What length should the collecting combs be, and how many points on each, and how far from the sectors? A drawing of the sectors would oblige.—W. J. P.

[51887.]—**Pyrogallol.**—On page 417, Vol. XXXII., there is given a simple method of preparing the above for dry-plate development. I have tried and failed. I proceeded thus. I obtained a tin saucer and put in a little sand; I then took a 2oz. gallipot and put in the glycerine, then the gallic acid, and stirred together, put them into the sand and then stood them all on a small paraffin stove, turned up the burner, and when the bubbles began to rise turned it down so as to just keep the bubbles rising; kept it so for about half an hour (I had no centigrade thermometer); when cold I tried a plate but got no result: I then tried another with double the amount of ammo., then I got a very faint image. I then tried with double the quantity of pyro., but with no better result. I bought the gallic acid at a photographic chemist's at 6d. the ounce, and the glycerine at an oilshop. I should be glad if some one would tell me where I was wrong and put me on the right road? I can take very good negatives with pyrogallic acid bought at a chemist's, with the same plates that I tried the above with.—Amateur Photo.

[51888.]—**Dynamo.**—I have a dynamo with Siemens H armature, and it will not work; will you oblige by pointing out the defects? The cores of the electromagnets are 7in. long, ½in. thick, 3in. broad, each wrapped with about 96 yards of No 18 wire. The armature is 2½in. diameter, 7in. long, wrapped with about 80ft. of wire same size as electro-magnets.—A. J. B.

[51889.]—**Hammering Cast Engine Rings.**—Can cast metal rings of a steam engine be hammered out to size of cylinder after they have been working till they are not steam tight?—if so, how is it done? I would also like to know if there is a way of hardening pincers for pinching waggons. I have a good many pincers to sharp, and they all come in soft. I heat them till they are a bright red heat, and then give them all the water; and they always seem to be soft.—D. W.

[51890.]—**Tubular Pneumatic Action.**—Would some reader well versed in organ building tell me just what is understood in England by "Tubular Pneumatic Action" and how it differs from the "Pneumatic Action"? If there are several varieties of pneumatic actions, a statement of their distinguishing features would be acceptable to others beside—U. S. A.

[51891.]—**Brazing.**—Will "Jack of All Trades," or any of ours tell me how to go to work to braze a hollow bicycle back to the solid neck. Could I do it at an ordinary fireplace?—or must I have a forge? Also, what appliances I should require, as I have never done any brazing before? Also is there any good practical work published on brazing and soldering?—C. B.

[51892.] — **Substitute for Beeswax.** — In my manufacture of a hair dressing, I use bleached or white beeswax, which suits my purpose admirably; but its price makes it a serious objection. Could I be enlightened as to some other wax or similar compound at a much cheaper rate? I may mention that I have tried spermaceti wax, and I found same, in common with Japan wax, to be unsuitable in their texture; they are very brittle, and consequently do not produce the same smooth pasty and beautiful elastic substance that wax does.—J. R. Wyllie.

[51893.]—**Simple Planing Machine.**—Can any reader oblige me with a description of simple planer to use in lathe, or otherwise, to plane fancy woods up to 3in.?—and please state if the same tool could be converted into a small moulding machine to strike mouldings up to 1in.?—Lumber.

[51894.]—**Model Marine Compound Engine.**—Will some of your correspondents kindly inform me if it is possible for the above engine, with crank at right angles, to work without an intermediate receiver between the cylinders?—Navire a Vapeur.

[51895.]—**Old Files.**—What treatment can I give old files, to make them grind easily on the stone, so as to make chisels and turning tools of them?—Semper Fidelis.

[51896.]—**Pise Blocks.**—Can anyone say how these were made, and describe their manufacture? I mean those made in England 30 or 40 years ago, of earth for the walls of houses.—Semper Fidelis.

[51897.]—**Battery for Continuous Work.**—Will Mr. Lancaster, or some other practical electrician, favour me with their opinion on the following points:—I have a shocking coil which I wish to keep in continuous action for 17 or 18 hours daily, and I require a suitable battery. The coil is 6in., diameter of core ½in., primary two layers 16 silk, secondary 12 layers 32 silk. With one Bunsen cell and the regulating tube half drawn, I get a shock I can scarcely bear, and with the tube fully drawn the shock is very powerful. I have had it on an ordinary telegraph battery, a six cell trough Daniel, with a surface of about 108 square inches of zinc exposed, and by coupling up for quantity I get a moderate shock. I think a Daniell could be adapted, and my idea is to make a box divided by porous divisions into five compartments capable of containing a plate 10in. square in each division, and by having two zinc plates alternating with three copper plates, the internal resistance would be low, and the zinc surface exposed would be about 400 square inches. As to constancy, I have three round Daniell cells now working the coil, and which have worked it without intermission for near upon 100 hours, and still no signs of flagging. If my idea is a feasible one, where can I get porous plates about 12in. square, or can anyone suggest a substitute, or give me instructions how to make porous plates? Also, can anyone suggest a good substitute for marine glue for lining the box? Is there any other description of battery that will work the coil, say for a month without recharging?—One in a Fix.

[51898.]—**N.B.R. Locos.**—Can any reader kindly give me the following dimensions of the single-driver locomotives on the North British railway, named Berwick and Glasgow, Nos. 474 and 475, diameter of cylinders and length of stroke, height of driving and leading wheels, height of chimney, and from top of chimney to rail?—Theodore Godfred Gassler.

[51899.]—**Medical Coil.**—I am in want of a compact electrical induction apparatus to give a power just a little too much for anybody to bear. I thought of having two small coils fitted into the brass handles; but a manufacturer says they would not act except wood be put between the coil and the brass tube. Will Mr. Lancaster, "Sigma," or any of our electrical correspondents kindly state if this is so? How many small (about 3in. long by 1in. diameter, or probably a little larger) would be required?—Thor.

[51900.]—**Thermo - Electricity.** — Can any of "ours" give any information about thermo-piles, for coils alluded to above? I have an idea that a thermopile to be worked by a methylated spirit gas blowpipe—the physician would have the gas with him—would be more compact, cheaper, and certainly not so malodorous or filthy as a hydro-battery. If some one will give a diagram of such a one (with blowpipe) that would work in the open air, I should be much obliged, but if thermopile not more compact than acid battery (with platinum plates) please give design for the latter instead.—Thor.

[51901.]—**Chief Rent.**—A. lets 360 square yards of land to B. on chief; B. in the course of time transfers it to C. with the building that is upon it; C. wishing to have a passage up the side of the building arranges with A. for one of 6ft. wide, which amounts to 60 yards, but has no lease or transfer as conveyance respecting it. Years roll on, and A. sells his chief of 360 yards, but the 60 yards not being in the chief, it does not go with it, and two or three years after the chief is sold, A. demands his rent for the 60 yards, but C. has parted with his building to D., and D. having no use for the passage does not like to pay for it. The query is, can A. compel D. to pay for the 60 yards which is of no use to him?—Alpha.

[51902.]—**Fine Spiral Springs.**—Can any reader tell me how fine spiral springs of brass or steel wire are made?—H. E. B.

[51903.]—**Colouring Iron Hoops.**—Will any reader kindly inform me of the best and simplest way of colouring or staining blue, new iron hoops on casks and tubs which have to be polished?—something similar to the blue stain on edged tools, that will not rub or chip off.—Oval.

[51904.]—**Lead Keel for Model Boat.**—Will any of your scientific readers give their opinions as to the best arrangement of the lead on keel? Some authorities say "let the weight behind be much more than at the bows"; but this makes the boat run off the wind. Others say "let the greatest weight be just abaft the centre, as the boat will thereby be more lively and ride better, as the weight in the centre acts as a pivot."—Wave.

[51905.]—**Tool Cabinet.**—Some short time ago I purchased a chest of tools of one of the firms that advertise in your paper with which I am thorougly satisfied, with the exception that, like all other tool chests that I have seen, the tools being of such diverse shapes do not permit of any arrangment in the chest or packing, but are all pell mell; so I have had a cabinet made to fix against the wall, 4in. inside from back to front, and I shall be glad if any of your readers will suggest some orderly way of arranging them, as I find this state of confusion is a general complaint, and one which many would be glad to know how to rectify.—Wave.

[51906.]—**Diaphragms.** — To Mr. Lancaster.—I have been making a set of diaphragms out of sheet brass, but cannot blacken them. I want a stain for them. I have tried strong ferri perchlor., but it does not make them dark enough.—J. C. B.

[51907.]—**Turbine.**—To Mr. Lancaster. — What power and light can I obtain from an inch pipe running constantly at 50lb., by means of a small turbine and dynamo, and what would the turbine cost?—B. D.

[51908.] — **Shakespeare on the Stars.** — To "F.R.A.S."—Pray what star does Shakespeare refer to in the first line of Act I. Sc. II., of "Winter's Tale": "Nine changes of the watery star have been the shepherd's note." Again, in the same play, Act V. Sc. I., Florizel is made to say—"The stars, I see, will kiss the valley first." What is meant by the stars kissing the valley? In "Measure for Measure," Act IV. Sc. II., the Duke says, "Look, the unfolding star calls up the shepherd." What is meant by the unfolding star?—Kelby.

[51909.]—**Texas.**—In a few weeks I am going out to Texas, farming and stock-raising. I should be very much obliged if any of the kind readers of "ours" would inform a strong healthy man with a small capital (and not afraid of work) how he had best proceed in procuring land, &c., and the best part of Texas to go to? Also, could they recommend me any good practical books on the above subjects.—W. F. J.

[51910.]—**Canadian Locomotives.** — Can any correspondent kindly give some information, with sketches of locomotives in use on the Canadian, Pacific, and other lines? Are there different classes for passenger, express, and goods traffic, and do they make as good time as English engines?—Russell.

[51911.]—**Employment in Canada.**—Can Mr. Tuttle, or other foreign correspondent, say what chance there is for draughtsmen and young inexperienced engineers getting employment on railroad or similar work in the States or Canada? Any information as to this, and also the mode of construction adopted, will greatly oblige.—Russell.

[51912.]—**To Violinists who are Mathematicians.**—Is there any mathematical principle which may be apprehended and applied in the tuning of the violin, so that it may, under such application, be infallibly pronounced to be in tune, irrespectively of or concurrently with (as that itself may or may not be accurate) what is termed the judgment of the ear? If so, what is that principle?—Student.

[51913.]—**Hydraulic Rams.** — Can any of your readers familiar with hydraulic rams kindly give me an answer to the following question?—It is stated over and over again by Mr. Davies and other writers that in some rams the fall of the pulse or outer valve after each stroke is secured by its weight alone, which counterbalances the pressure of the trunk water when at rest. If this is so, it is easy to calculate the required weight for any given case—e.g., a 3in. valve worked by a 10ft. fall would have to weigh a little over 30lb. This would be a small ram for ordinary sizes. The weight (increasing as the square of the diameter) would be three or four times as great. My question, then, is this Do any of your readers happen to know of rams actually in existence having outer valves weighing 30lb., or anything like that weight, and if so, where should I have a chance of seeing one?—W. A. S.

[51914.]—**Feed-Pump.**—Can any reader give me design of feed-pump, with dimensions and amount of water to be delivered at each stroke, to supply boiler of model portable engine, pump to be bolted on side of boiler direct under crankshaft, worked from an eccentric on same; size of engine—cylinder, 1¼in. bore, 2in. stroke, steam-pressure 15lb. on sq. in. Also, do you think the above-named cylinder over-large for a boiler of the following dimensions?—Length of boiler shell 9in., diam. 5in., with firebox 8in. high; 5 by 5½ sq. internal firebox, giving water space all round; 20 tubes ⅜ diam. What would be the best fuel to burn for this size of boiler?—Stultis.

[51915.]—**Batteries in M.R. Signal Boxes.**—Will any of our readers inform me what kind of battery the Midland Railway Co. use for their signal boxes, and if they use earth return or not?—A Lover of Ours.

[51916.]—**Gasometer.**—Can any of our readers give a description of how the different ways of getting the oxygen gas out of the tanks is done in the theatre for the limelight? By some it is pumped out, and I have seen the gasman get it out without pumping at all. There are two tanks and a retort.—G. A. S.

[51917.]—**Battery for Bell.**—In some shop-windows I have seen an electric bell and battery combined. The cell is a zinc one with a carbon rod in the middle, and packed around with some kind of salts. Can any of our readers tell me of what the cell is composed, and how charged?—G. A. S.

[51918.]—**Eyepiece.**—Will any reader tell me how to construct an erecting eyepiece, cheap, and with as large field as possible? The o.g. is 2¾ Wray's, 42in. focus. want a power of 42 dia. Will three 1in. plano-con-give me the power, or must there be a double convex between the field and middle one? If so, of what focus must the double convex be, and what distance must they be placed apart? Is the polar star a good test for a 2¼, and if it shows the companion of polar star, would it be possible to see division in the Ring of Saturn, or any of its satellites? I have often split the polar star, and I fancy I have seen the division in Saturn's ring.—A. Best.

[51919.]—**Ampere Meter, &c.**—Will some kind reader give me the directions how to make a volt and ampere meter? Hints, &c., will be thankfully received by—Volt.

[51920.]—**Dross.**—I have a large quantity of dross from type metal by me. Will some reader give me directions how to recover the metal from it? It can be done, for up till lately I have sold it to a large London metal refiner, who would not buy it if he did not get something out of it.—Volt.

[51921.]—**Model Steamer.**—I am anxious to build a model steamboat on the lines of the Guion steamers, length to be about 4ft. 6in., and shall feel very thankful if any reader will kindly give me a small sketch of the framework ready for planking. The engine for her I have already. It is launch pattern, 1¼ by 2in. cylinder, inverted, and ought to drive her at a good pace. What size screw propeller and boiler should I require? Also, where could I get scale drawings of launches and large steamboats, ironclads, &c.? Any information will be sincerely appreciated.—Paulatim.

[51922.]—**Model Steam Pump.**—I have a model of a Universal steam pump: bore of steam cylinder 1¼in., stroke 3½in., and wish to make it into a model steam fire-engine, after the pattern of those manufactured by Merryweather, of London; but am at a loss as to size of boiler—which must be a vertical one. The boiler I propose to make of copper, with tubes. The engines made by Merryweather have a "Field" boiler, with tubes projecting into the firebox; but where to get tubes of, say, ⅜in. or ½in. stopped at one end, I do not know, so must endeavour to make them, and shall be glad if any fellow-reader will give me a wrinkle or two.—Volunteer Fireman.

[51923.]—**Damp Cellar Vaults.**—I have some arched cellar vaults, the brickwork of which lets in the damp from the surrounding clay. What is the best way of rendering them dry, if any, and what would be the cost—which must be low?—Inquirer.

[51924.]—**Staining Golf Balls.**—Can any correspondent give directions for staining golf balls a bright red? This colour is much more easily distinguished than white upon grass, and especially upon shingle. I have tried red sealing-wax dissolved in spirit, but this soon chips off.—Hayling Island.

[51925.]—**Ink.**—I should be glad if any subscriber could give a reliable recipe for stencil ink, black, red, and green, and if possible the latter not poisonous?—No. 23.

[51926.]—**N.R. Locos.**—To "Meteor."—Wanted list of goods engines stationed at Wellingborough, London, Bedford, Leicester, Nottingham, Skipton, Carlisle, and Manchester.—J. E. Spencer.

[51927.]—**Boilers.**—To "Boswell." In your reply to "The North," of August 10th, is just what I am wanting. I wish to be my own boiler inspector, but do not know how to get the bursting or working pressure of boilers. I can do plain figures up to decimals, but I do not understand the [illegible] in that the tensile strength of all metals or boiler plates? Will you be as kind as to give me the bursting pressure of our boiler? also working pressure? Diameter of boiler inside, 6ft. 11in., length 24ft. 1in., diameter of fire-tubes 2ft. 10½in., four tubes in each flue, 9in. at one end and 4½in. at the other, plates ½in. thick, ends ⅝in., fire-tubes ⅝in. Also, what will be the horse-power of same? Also is the book that you mention to "The North," in plain figures, as it will be no good to me if not?—Young Engineman.

[51928.]—**Spectroscope.**—What are the indications in this instrument that foretell rain? I have got a small pocket or "rain band" spectroscope, and would like to know what experiments I may produce with it, and how to diagnose the weather.—A Spectre.

[51929.]—**Microscope.**—In the last Vol. of "E. M.," there is an article on the curious hirsute covering of the paramecium when a solution of quinine is added to the water in which the creature swims. Has any of our microscopists verified this experiment? The so called hairy covering appears strangely like a fungoid growth, or a sudden crystallisation of the quinine. As the living creature swims past other animalcula, I cannot see the least indication of those long hairs or cilia which cover the dead specimen.—E. B. Kennedy.

[51930.]—**Teazles.**—Are teazles used nowadays in the woollen industry, and where are they grown? Are they wild [illegible]? What is the cultivation? I want a few to see what they are like, as I read that in 1859 about 19 million heads were imported from France and sold at five shillings per thousand. It is the Dipsacus Fullonum, not the wild species, I mean. I think it might be cultivated on waste places in Ireland and elsewhere.—P. R.

[51931.]—**Lathe.**—Will some one kindly help me out of the following difficulty? I am about fitting up a 4in. lathe, and am in ignorance as to what height to make the standards. I am 5ft. 9in. high, and should be glad if some reader would give me his experience as to what height the surface of bed should be from ground, so that I may get the best command over the work. Also, which is the best plan to adopt with reference to fixing the driving wheel: keyed on a crankshaft, or made to run on a stud projecting from the standard? Any further hints as to the simplest way of fitting up, would be gladly received by—W. H.

[51932.]—**Parasites on Bees.**—I have just discovered that several of my hives are infested with a large brown parasite, which I believe to be Braula cœca. One hive in particular is so bad that nearly every bee is affected. This hive is rather weak. All the others, more or less affected, are very strong. Is it possible to get rid of the pest, and how?—[illegible]

[51933.]—**L. & N. W. Locos.**—Of whose design are [illegible], and in or about what year were the engines of the classes to which the following belong, respectively, rebuilt?—304, 531, 604, 148, 1005, 980, 958, and 1888.—J. E. Spencer.

[51934.]—**Legal.**—I should be glad to have the following question answered by Mr. Wetherfield:—S., a married woman, died in 1837, and left a legacy to her niece, M., but it was not to be paid till the death of her husband. He died in January, 1883. Is M., who is a married woman, entitled to the benefit of the Married Woman's Act that came into operation on the 1st of January, 1883?—W. T.

[51935.]—**The Law of Copyright.**—To Mr. Wetherfield and Others.—Can Mr. Wetherfield or any of your readers tell me what is the law as applied to the following case?—A. contributes an article to a magazine, and is paid for it by the proprietors. Other publications copy it, without so much as acknowledging the source. With whom does the right of action lie, if any action can be brought at all?—E. G.

CHESS.

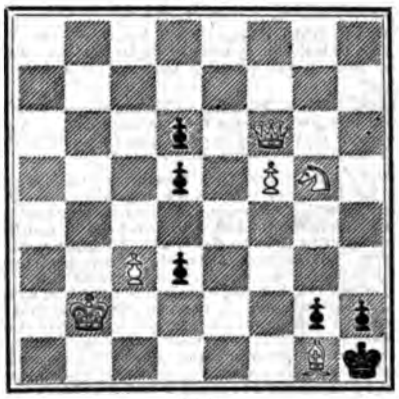
PROBLEM DCCCLV.—"Who's Afraid?"

Black.



White. [6+6

White to play and mate in three moves.

Solution to 853.

White.	*Black.*
1. Q to Q Kt sq	1. Anything
2. Q, R, B, Kt, or P mates	

(Nine variations.)

NOTICES TO CORRESPONDENTS.

Correct Solutions to 853 by Mortimer, D. Mackay, C. Planck (neat and well constructed, but rather easy), Dicky Sam, R. A. Bennett, J. B. of Boxford (extra good), A. E. S., G. S. Follwell (the best two-mover: this puzzler about it—five or six likely first moves with mate in all the variations but one: very clever and enjoyable); to 852 by Dicky Sam.

G. S. Follwell.—We replied to your query last week.

J. B. of Boxford.—We wish there were ten times the number of solvers: but "though you bring a horse to water, you cannot make him drink." Please send solution always. Problem can still be done—thus, 1. B-K 8, 2. K-Q 4, 3. K-Q 5, 4. Kt mates.

Game received with thanks from H. B. Reynolds.

English Mechanic Tourney game between J. H. Blake (*White*) and J. Jowett (*Black*).

(Scotch Gambit.)

1. P-K 4, P-K 4 / 2. Kt-K B 3, Kt-Q B 3 / 3. P-Q 4, P takes P / 4. Kt takes P, B-B 4 / 5. B-K 3, Q-B 3 / 6. P-Q B 3, K Kt-K 2 / 7. Q-Q 2, Castles / 8. Kt-Kt 5, B takes B / 9. Q takes B, Q-K 4 / 10. Kt-Q 2, Kt-Kt 3 / 11. Kt-K B 3, Q-K 2 (*a*) / 12. Kt takes B P, R-Kt sq / 13. Kt-Q 5, Q-Q sq (*b*) / 14. B-K 2 (*c*), P-Q 3 / 15. Castles K R, P-Q Kt 4 (*d*) / 16. Q R-Q sq, R-K sq / 17. Kt-Q 4, Kt takes Kt / 18. Q takes Kt, P-Q R 3 (*e*) / 19. P-K B 4, Kt-K 2 (*f*) / 20. Kt takes Kt (ch), Q takes Kt / 21. Q takes Q P, B-Kt 2 / 22. P-K 5, P-K B 3 / 23. B-Kt 4, P takes P / 24. B-B 5 (ch), Resigns (*k*).

Notes.

(*a*) Why not Q-B 5?
(*b*) Nothing better: but sadly defensive.
(*c*) R-Q sq looks more forcible.
(*d*) Ditto P-K B 4.
(*e*) Weak again; B-K 3 or R-Kt 2 is far better.
(*f*) This loses Q P. It would probably have to go in any case, but B-Kt 2 seems stronger.
(*g*) All this, though it isolates the P, is playing White's game; but has he anything else?
(*h*) If R-Kt 2, R-B 8, ch, &c.
(*i*) B-K 5 might have prolonged the torture.
(*k*) For if 31. $\frac{}{\text{K-Kt 4 or R 4}}$ 32. $\frac{\text{R takes K Kt P}}{}$ and forces mate in a few more moves; and if 31. $\frac{}{\text{K-B 3}}$ 32. $\frac{\text{R-K 8 (ch)}}{\text{K moves}}$ 33. $\frac{\text{R takes B}}{}$ Altogether Black's play has not been brilliant.

ANSWERS TO CORRESPONDENTS.

⁂ *All communications should be addressed to the* Editor *of the* English Mechanic, 31, *Tavistock-street, Covent Garden, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

⁂ Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

BACK NUMBERS.

We receive so many queries asking for directions how to make many instruments and appliances which have been fully described in back volumes that we have compiled a list, which we shall insert in this column at intervals, of those most frequently sent, and as the numbers are still in stock, new subscribers should consult the list before sending their questions.

Batteries: Nos. 715, 718, 721, 724, 728, 731, 734, 741.
Bellows camera: Nos. 475, 480, 894, 897.
Bookbinding: Nos. 613, 627, 770.
Cements: Nos. 377, 729.
Coils, induction: Nos. 620, 640, 779, 797, 832, 885
Coils, medical: Nos. 844, 898.
Copying processes: Nos. 750, 753, 761, 762.
Electric bells: Nos. 545, 558, 797.
Electric machines: Nos. 368, 380, 628, 759, 840, 846.
Electro-magnets: Nos. 756, 772, 783, 864, 872.
Electro-plating: No. 833.
Lacquers: Nos. 429, 475, 622, 866.

Novice. (Either direct or through an agent—preferably the latter.)—W. H. O. (Hardly worth further discussion, we think.)—A. A. B. (We should not trust them with a halfpenny, nor any similar advertisers.)—Condensed Water. (Published by Munn and Co., New York.)—A. Best. (Please send.)—J. T., Barnsley. (Any query or criticism shall appear; but it is useless occupying space simply with an invitation to others. We believe the author intends republishing; but information on this point had better be sought from him direct.)—W. J. Grey. (Thanks for your very kind offer: but we fear the matter is hardly of sufficient *general* interest.)—John Elliott. (The correspondent you mention, and others who think with him, would readily enough admit with Tyndall and Huxley that "the first step" is not yet proved, but their condition of doubt, if doubt it be, is certainly not dogmatism. The whole question is a fascinating one, but space forbids a further extension of the controversy. We began with "Transfer of Thought"; you see already where we have got to, or, rather, where we haven't got to.)—Wolfenbuettel. (A very pretty quarrel you would land us in. How long do you think it would be before the disputants on either side would be at each other's throats?)—Douglas. (It could do no harm in itself, being a simple and remarkably efficacious ointment, largely used by medical men; but it is a dangerous thing suddenly to close up old wounds of the kind referred to, especially without medical advice. Inconvenient as such ailments may be, they frequently act as safety valves, and their sudden closing may result fatally.)—J. McE. (Prussiate of potash solution, to which has been added a little nitric and hydrochloric acid. 2. Depends on the arrangements. 3. Depends on the speed. See the report of Captain Galton's experiments.)—W. Kingdon. (Methods of making oxygen gas can be found in any textbook, and several processes in our back numbers. See pp. 422, 424, 450, 475, 493, 519, 529, 547, 591, Vol. XXXIV.)—S. J. S. (Your question has been answered many times as fully as it can be. The number of cells depends on the resistance of the lamps. Most likely you will have to use about fifteen.)—Crux. (You do not say what sized lamps. However, make up a battery of 30 quart Bunsen's, and try what you can do with them. Keep battery outside the house. Read the preceding answer.)—

work without nails, which I will leave for [illegible] [illegible] [illegible] [illegible] no nails inserted [illegible] into the ends of the shelves, and [illegible] them [illegible] efficient. Now, to conclude, I would call attention to the following [illegible] of a satisfactory job of this kind:

1. Very sharp tools.
2. Careful gauging and marking out.
3. Leaving all such gauge lines on the work, sawing and chiselling inside them.
4. Level and true planing.
5. Grooves of equal depth and width.
6. Straightly cut edges and chamfers. Mark these by gauge, and plane exactly to to line. Do not fancy you can work without gauge lines.

O. J. L.

PRACTICAL NOTES ON PLUMBING.—LXXXI. LXXXII.*

By P. J. Davies, H.M.A.S.P., &c.

([illegible] from page 80.)

Service-Pipes from Street Mains.

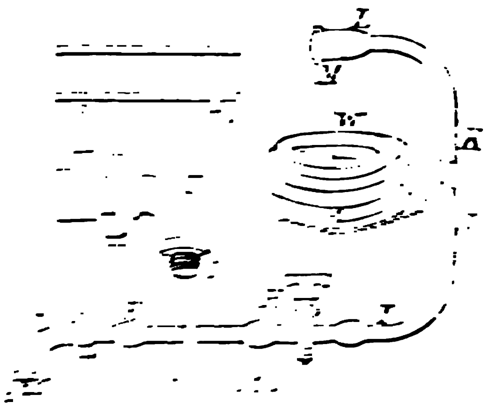
In laying these mains one uniform method [illegible] adopted. They are or should be laid at a depth of 2ft. 6in., and out of the reach of the frost.

It is always advisable when the ground has to be [illegible] to apply to the water company, as in many [illegible] it themselves, whilst in other [illegible] has to get it done. When [illegible] plumber invariably has [illegible] local board authorities [illegible] up the road.

[illegible] to deposit a sum of £1 [illegible] After the work is completed [illegible] to the satisfaction of the [illegible] is refunded.

Lead Pipes.

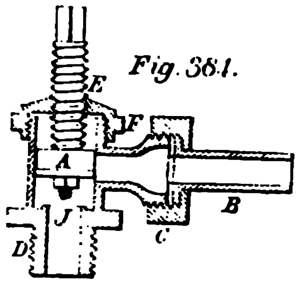
[illegible] this kind of work are [illegible] W., Fig. [illegible]

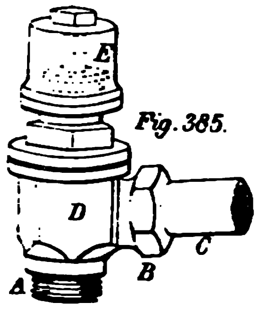


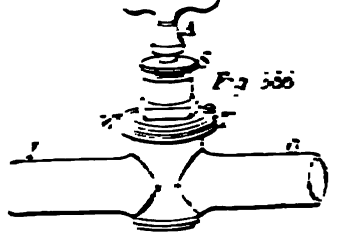
[illegible]

C is soldered on to the lead pipe, as shown at C E F. At S T U V is shown a ferrule for iron barrel screwed at C.

At Fig. 384 and 385 is shown a kind of stop-valve ferrule suitable for shutting off the water. A is the valve and J the seating, C is the union nut and B the lining, E the screw for working the valve, and F the top. In this valve it may be seen that the water has every chance of passing between the screw and the top, but on closely examining the diagram it will be seen that under the cap is fixed a leather washer, and by turning up the top part of the valve tight against this washer all chances of a by-pass is stopped. If you closely examine the end of the lining at Q, Fig. 383, and at 4 and 5, Fig. 394, you will see that the end of the lining protrudes into the union, which will prevent a solid disc being placed between the end of the lining and the end of the union. Now examine C, Fig. 384, and 6, Fig. 394. The end Q of the lining Fig. 383 is cut off at the dotted lines, and a leather washer, as shown at C, 384, and at 6, Fig. 394, can be placed between the end of the lining and the end of the ferrule or union; but suppose instead of this leather washer that a plain disc of leather be used, it will be plain that no water can pass, and should the pressure be too strong a copper [illegible] at the back of the leather [illegible]. This is a very good plan for turning off the water. I have used plumbers' unions having the end of the lining cut off as at 6, Fig. 394, for stopping off the water, [illegible] with the aid of the valve A, Fig. 384, [illegible] with the [illegible] A B and S T U V, Fig. [illegible] a valve-screw ferrule with a [illegible] at the spindle, and which is [illegible] E. In the [illegible] may be seen the method of [illegible] [illegible] is the best that can be [illegible] water companies [illegible] [illegible] This is known as the







[illegible]

passage through this cock has so many sharp corners (see section, Fig. [illegible]) it greatly adds to the power required to force the water from the main into the house, and I for one should certainly not use it, that is, if I should have to pump the water. If a valve-cock must be used, then the water companies should, for their own sakes only, use one which has a straight waterway through it, as shown at Fig. [illegible]. This also applies to ball valves. I may add that such ball valves are made. It is quite possible to fix the [illegible] cock the wrong way about—that is, to make the inlet the outlet (see Fig. [illegible] &c.). A is the inlet; should you make B the inlet, the force of water will be upon the valve, and consequently will tend to keep it closed. In such cases the cock should be reversed; but the difficulty may be got over by soldering the jumper of the valve to the spindle. But if such an occurrence takes place, keep it to yourself and away from the ears of the water company; though in point of law they cannot make you alter it, because the cock is of the screw-down kind, and the Act says nothing as to whether the valve should be a fixed or a loose one. Having fixed the stopcock, see that it is well down and fixed out of the way of the frost, and in such a position that it is accessible and can be easily got at for releathering.

The stopcock when fixed below ground should be protected with a proper cover, as shown at Figs. 387 and 388. The former is one made by J. Tyler and Sons, and is used in many parts of

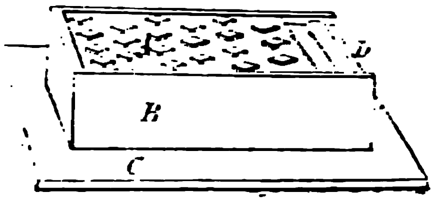


Fig. 387.

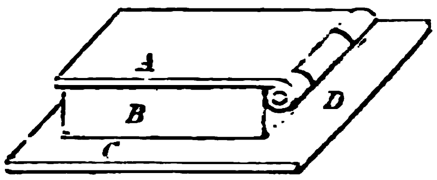

Fig. 388.

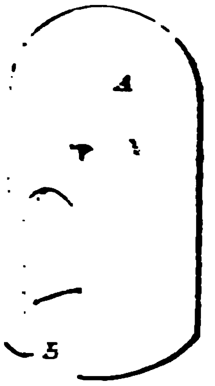

[illegible]

[illegible] In this the lid shuts below the top [illegible] and this I don't approve, because [illegible] when the frost is about, it [illegible] I have designed a box cover [illegible] Fig. 388. In this diagram [illegible] be seen that the lid shuts down fairly [illegible] and therefore dirt or frozen [illegible] the opening at any moment. [illegible] an ordinary cock or ferrule cover for [illegible] &c., in the street, and [illegible] where the earth is thrown over the same. The opening [illegible] is to receive the [illegible] Fig. 384; or for a [illegible] as at B. Wh[illegible] [illegible] is used, the cock with hay, &c., properly protected from

Building Supplies.

simply a main run, as at Fig. 383. The an is to lay the main as a permanent the house, with a stopcock on the nd near the street; the other end may to a tub, cistern, &c. But on the end, , must be fixed a ferrule and screw- :, such as shown at Fig. 390. Or if a used, an ordinary ball valve may be : soldered on. When the main is run, ppens that a garden or fire-hose supply l to be fixed. There are hundreds of orts of valves suitable for this purpose; e I prefer to fix is that shown at Fig. it at Fig. 392.

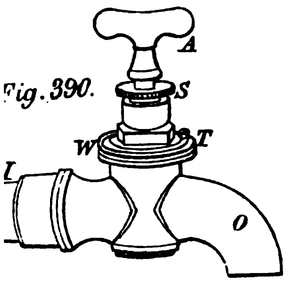

Fig. 390.

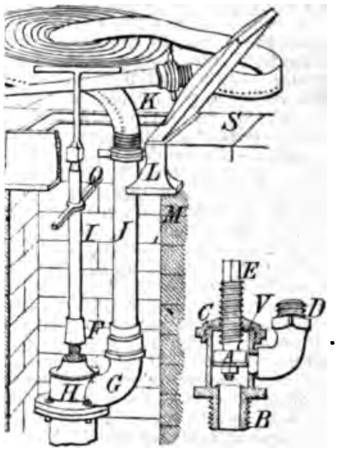

Fig. 391.

391, at H, may be seen fixed a fire alve, with hose and cover complete, the which externally is somewhat different, asily be understood. It is plainly to be the valve A is capable of shutting off , and when screwed up against the top the washer V be right, the top part of will prevent the escape of the water he spindle hole and the sides of the pindle, though some would here use a ox; but I do not, for the simple reason the valve A is shut down upon the inlet seating, the spindle and top hole not fitting too tight, the water will be allowed to run out of the stand pipe and other parts above the valve, which will prevent the stand pipes and top parts of the valve bursting in times of frost. Should the top or body of the valve be required to be water-tight at that part round the spindle, this may be accomplished by the use of the stuffing box or cup leather, or by the diaphragm fire hydrant, as shown at R A E B, Fig. 392, and Fig. 397, which also illustrates the method of fixing the same with key and hose in action. On turning open the valve, the water will force open the diaphragm and pass up the outlet E, and into the hose F D J, &c., where it may branch off at any number of branches, as shown at I J K, &c.

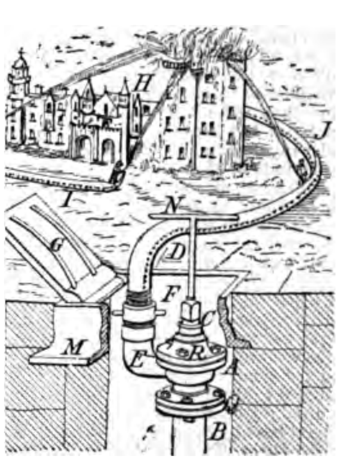

Fig. 392.

The method of fixing the valve upon the flange pipe B, and at Q, will be thoroughly understood by the plumber. All that is to be kept in view is to get suitable packing for the bedding between the flanges. I sometimes use felt, at other times canvas, old bagging smeared over with red lead and boiled oil, at other times leather or india-rubber washers. These may be purchased ready made, up to any size. I think the last named is the best when the expense is not studied, and for a superior class of work. I should add that the hose should be fixed on the union F with good strong copper bell wire, not too thick, so that it may easily be bound round. Fold it neatly round, and fix the one end, which you commence with in such a manner that the other will overlap it, then bring this end to the part where you leave off, and with your pliers fasten the two well together, or the finishing end may be fastened in the same manner that a scaffolder would fasten the ends of scaffold cords.

OBJECT-GLASS WORKING.—VIII.

(By "PRISMATIQUE.")

WE will suppose that the lenses are now roughed out fairly true as to parallelism round the edges, and due allowance made for the little alterations that will be made in their thickness in the processes of truing and smoothing. A very simple way of making smoothing tools where it is advantageous to avoid expense, and when one has plenty of time, is the following:—Models are turned of 1½in. pine, one for each curve, fitting the gauges as truly as possible, and twice the diameter of the aperture of the intended o.g. These models are a simple job to any one having a lathe; the castings should be got as quickly as possible, and directions given to the moulder to cast them *curved* face down, and to turn the models round in the sand, so that the castings may be as circular as possible. Fig. 9 gives sections of models. To avoid the expense of screw-cutting in each tool, a block of wood with a suitable thread to screw on the post, or bench screw will answer for all the tools, which, as will be seen, are flat at the back; in fact, to more simplify matters, these tools may be stuck down with pitch on the bottom of a barrel, or anything that one can reach and walk round. If these tools are *turned* up to the gauges, they can be finally trued up by casting a plate of lead in a ring fastened round the edge; this leaden plate doing duty all round by being melted and cast on each curve as the last is done with. The leaden casting does not fit when cold, but must be scraped to touch approximately, so as not to flatten or deepen the tool. If the turning of the tool surfaces is not convenient, a number of broken pieces of old files cemented into the leaden casting with pitch, and pressed on the tool, will, with patience, file it up to as perfectly a spherical surface as can be got on the lathe by turning; it is, of course, necessary to continually try the fit on the gauge, taking short straight strokes if there is a tendency to deepen the convex tool, and a circular sweeping stroke if the tendency is to flatten: with the hollow tool the reverse is needed. Many years ago this method was used in the trade; but now all tools are made in pairs, and ground true together. This is, of course, the better plan for the trade. The above directions are suited admirably for amateurs. 120 hole emery is a good size to true the lenses up to finishing tool, finally using flour emery of commerce divided into two sizes by washing. The lenses are held bare for the truing up, and the final callipering carefully done, when they are ready for smoothing and polishing.

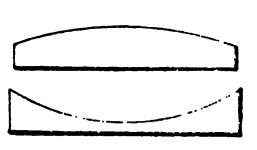

Fig. 9.

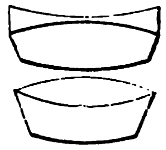

Fig. 10.

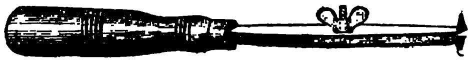
The lenses must now be cemented to a "mallet" or "back." A very simply-made back is a piece of cork cut something like a bung, with the smaller diameter exactly equidistant between centre and edge of the larger, the larger diameter the same as the lenses, the height ⅞in. The faces must be scored off to something near the curve they are to be stuck on; this I manage simply by pitching them on the lathe and scouring them out with coarse glasspaper to the required gauge. Fig. 10 is a section of cork back. To stick the glass on, a mixture of pitch boiled and hardened with finely-sifted yellow ochre, is used; this cement must be kept sufficiently plastic by heating to give to the shape of the curve with very little pressure. A good plan is to warm the tool and glass together, then have about ¼in. of the pitch already warmed and spread on the cork, and, placing the cork centrally on the lens, gently and lightly press until adhesion is complete. The pitch should be convex when warm, so as to exclude all air as the pressure is applied. Cork backs can be used for all sizes up to 4½in., but are not suitable for much larger sizes.

(*To be continued.*)

SERVICE'S POINTING KNIFE.

WE have a tool before us, patented by Mr. Service, of Bow, and sold by Messrs. John Russell and Co., Limited, of 145, Queen Victoria-street, London, which will be welcomed by the building trades as the means of a great saving of labour in pointing the brickwork of a house. It is used with the straightedge, and cuts the mortar on both sides at the same moment; it is adjustable to any required width of pointing; it performs its work in a very superior manner, and in one-half the time. The price is but 3s., and this is saved in one day's use. If it will do all that the patentee professes it will do—and we do not think his expectations are extravagant—every brick house ought to be pointed. The advantages claimed are: Saving of one-half the time occupied in cutting, and the ability to employ cheaper labour; an inexperienced person can use it, and the work is accurate and neat in appearance.



ALUMINIUM AND ALUMINIUM ALLOYS.

ANOTHER process for the reduction of aluminium has been recently patented in this country. This time the inventor is Mr. H. Niewerth, of Hanover, who also patents a special kind of furnace. The specification is No. 362, of 1883. In his first process ferro-silicium is mixed with fluoride of aluminium in proper proportions and the mixture is submitted to a suitable red or melting heat, when the charge is decomposed into volatile silicon fluoride, iron, and aluminium, the two latter bodies forming an alloy. In order to obtain the valuable alloy of aluminium with copper from this iron-aluminium alloy the latter is melted with metallic copper; the copper will then, by reason of greater affinity, unite with the aluminium, while the iron will retain but an insignificant amount of aluminium. On the mass cooling the copper-bronze and iron separate out in such a manner that both bodies can be readily isolated. In place of the pure aluminium-fluoride, cryolite, which occurs in nature, may be advantageously employed, or aluminium chloride may also be used. In the latter case silicon chloride and iron aluminium alloy are formed. Or again pure silica and aluminium fluoride, or cryolite, or aluminium chloride may be used, when pure aluminium is obtained. In the second process the compound of aluminium with chlorine or fluorine decomposed by any means into a volatile state is brought, strongly heated, into contact with a mixture of 62 parts of carbonate of soda, 28 parts of coal, and 10 parts of chalk, which is also in a highly heated condition. From this mixture sodium is disengaged, and this reduces the gaseous fluoride or chloride of aluminium in such a manner that the nascent sodium generates free aluminium from the fluoride or chloride as the case may be. In place of the above mixture other suitable mixtures which produce sodium may be employed, or mixtures may be also advantageously used from which potassium is formed. In another process the newly invented furnace may be advantageously employed, but the process may also be carried on in a crucible or other furnace. The furnace in question consists of three shaft furnaces made of fire-resisting material, two of which are made to shut by means of some contrivance, *e.g.*, a convex cast-iron cover. These furnaces communicate with the other furnace by channels, which can be closed by slides. Blast pipes are fitted to two of the furnaces, and all three are fitted with discharge apertures. Short tubes connected with a steam reservoir admit steam to the two furnaces, which are filled with some suitable fuel, *e.g.*, coke, and by the admission of the blast are blown very hot. The covers are meanwhile lifted up. The middle furnace is then charged with three charges in proper order. The first charge consists of a mixture of carbonate of soda Na_2O,CO_2 + Carbon C + Sulphur (S) + Alumina, Al_2O_3. The second charge is sulphate of alumina, the third charge a flux, preferably a mixture of the chlorides of soda and potash. This furnace must be strongly heated at the beginning of the operation; it is best to fill with coke first, and as soon as that is warm to put the charge in the coke so that it comes to the bottom with the burning coke. A mixing of the charges with coal is not excluded, but is usually not necessary.

The process then continues as follows:—The cover of the furnace is shut down, the slide drawn up, and the blast cut off. A suitable quantity of steam is now admitted which spreads itself over the glowing coke and penetrates downwards through it, breaking up into its constituent parts oxygen and hydrogen. The oxygen forms with the carbon of the coke carbonic oxide gas, while the hydrogen remains uncombined. The gases thus formed during their passage through the extremely hot coke themselves acquire a very high temperature, and at length pass by a channel into the third furnace [illegible]. The highly heated gases, carbonic oxide and hydrogen, act upon the charges so that the first charge breaks up into a combination of sodium sulphide and aluminium sulphide, from which, by means of the second charge [illegible] alumina, free metallic aluminium is formed. Passing into the melting [illegible] will melt, and, if it be drawn [illegible] thereof, will assist the fusion of the [illegible]; it is not, however, [illegible] necessary. When the gases generated in the [illegible] the second furnace [illegible] the coke having been kept [illegible] the processes are repeated.

Instead of the bimetallic sulphide, pure [illegible] may be employed, or a [illegible] it is generated, or, again, [illegible] sulphide of potash, sulphide [illegible] sulphides or analogous [illegible] the same effect alone. In [illegible] obtained in combina[illegible] sulphide. Instead of [illegible] carbonate of soda + [illegible] a mixture of alumina, sulphur, [illegible] introduced, or further the [illegible] may be replaced by alumina. [illegible] may also be formed out of [illegible] potassium sulphide, and other [illegible] may be produced [illegible] of alumina.

THE SIX GATEWAYS OF KNOWLEDGE.

At the recent distribution of prizes to the students of the Birmingham and Midland Institute, Sir W. Thomson, the president, delivered an address, of which the following is an abstract:—He said, in commencing, that if he were asked to give the subject of his address a title, he might call it "The Six Gateways of Knowledge"—that subject being closely connected with the studies for which the prizes had just been presented. The question he was going to ask them to think of was—What were the means by which the human mind acquired a knowledge of external matter? John Bunyan likened the human soul to a citadel on a hill, self-contained, with no means of communication with the outer world except by five gates—viz., the eye gate, ear gate, mouth gate, nose gate, and feel gate. Bunyan was clearly in want of a word there. He used feeling for the sense of touch, a designation which to this day was sometimes so commonly used that he could scarcely accuse it of being incorrect; at the same time, the more correct designation undoubtedly was the sense of touch. The late Dr. George Wilson, first professor of technology in the University of Edinburgh, wrote, sometime before his death, a beautiful little book under the title of "The Five Gateways of Knowledge," in which he quoted John Bunyan in the manner he had indicated. He had said, however, six gateways of knowledge, and he must try to prove that we had six senses. The six senses he intended to explain were the sense of sight, the sense of hearing, the sense of smell, the sense of taste, and the sense of touch. The sense of touch, however, must be divided into two departments. The sense of touch was very distinctly of double quality. If he took up a particular body he perceived a complication of sensations, a certain sense of roughness, but he also perceived a very distinct sensation which was not of roughness or smoothness. There were two sensations. If he dipped his hand into a bowl of hot or cold water, the moment he touched the water he perceived a very distinct sensation. That was not a sense of roughness. The sensation of the cold water was comparable with the sensation of heat, although it was opposite. Still it was comparable with the sensation of heat. He was not going to say they had two sensations in that department—a sense of heat and a sense of cold; he should endeavour to explain the sense of heat. The perception of heat and cold were perceptions of different degrees of one and the same quality, but that the quality was different from the sense of roughness. The sense of roughness was the sense of force, and the six senses which he wished to explain were the sense of sight, the sense of hearing, the sense of taste, the sense of smell, the sense of heat, and the sense of force. The sense of force was the sixth sense, or rather the senses of heat and force were the sense of touch. He had hinted at a possible seventh sense—a magnetic sense. He wished, however, in passing, to remove the idea that he was in any way supporting that wretched grovelling superstition of animal magnetism, spiritualism, mesmerism, or clairvoyance, of which they heard so much. There was no seventh sense of the mystic kind. Clairvoyance and so on was the result of bad observation chiefly, somewhat mixed up with the effects of wilful imposture acting on an innocent and trusting mind. If there was not a distinct magnetic sense, it was a very great wonder that there was not. The study of magnetism was a study of a very recondite subject. One very wonderful discovery that was made in electric magnetism was made by Faraday, and worked out very admirably by Foucauld, an excellent French experimenter, showing that a piece of copper or a piece of silver let fall between the folds of a magnetic field would fall down slowly as if through mud. Was it conceivable that if a piece of copper could scarcely move through the air between the poles of an electric magnet, that a human being or living creature in the same position would experience no effect. Lord Lindsay got an enormous magnet, so large that the head of any person wishing to try the experiment could get well between the poles, and the result of the experiments was marvellous—the marvel being that nothing was perceived. He, however, did not admit, he did not feel, that the investigation was completed. He could not but think that the quality of matter in the air, which produced such a prodigious effect on a piece of metal, could be absolutely without any—it was certainly not without any—effect, but that it could be absolutely without any perceptible effect whatever on a living body. He thought the experiment was worth repeating, worth examining, whether or not an exceedingly powerful magnetic force was without perceptible effect on a living vegetable or animal body. He thought, therefore, there might be a seventh, or magnetic, sense, and that it was possible an exceedingly powerful magnetic effect might be produced that could not be explained by heat, force, or any other sensation. He then referred to the sense of hearing, describing it as being distinctly a sense of varying pressure of air. The increase of pressure one experienced on going down in a diving bell was absolutely painful to the tympanum.

An example of graphical illustration might be taken from the recent mathematical treatise placed before the British Association by the President (Professor Cayley), who insisted very much upon the importance of such illustrations. In the language of mathematics, they had just "one independent variable" to deal with, and that was air pressure. Any one thing that varied was an independent variable. Don't let them imagine that mathematics was harsh, and crabby, and repulsive to common sense. It was merely the etherealisation of common sense. Now, in a thousand counting houses and business places in Birmingham, and London, and Glasgow, and Manchester a curve—as Professor Cayley pointed out—was regularly used to show to the eye the function of one independent variable. Most important, in Liverpool, perhaps, might be the price of cotton. A curve was used to show it, rising when the price of cotton was high, and sinking when it was low. So in the Registrar-General's tables of mortality. One of the most beautiful results of mathematics was the means of showing to the eye the law of variation, however complicated, of one independent variable.

Light we know to be an influence on the retina of the eye, and though the retina on the optic nerve, an influence dependent on vibrations, whose frequency was something between 400 million millions, and 800 million millions per second. There was a vast gap between 400 vibrations per second, and the sound of a tenor note, and 400 million millions, the number of vibrations corresponding to dull red light. the gravest light of the prismatic spectrum. With violet light we had 800 million million vibrations per second, and beyond that there was something which the eye scarcely perceived, or did not perceive at all—he believed did perceive, but not vividly—ultra-violet rays, known to chiefly by their photographic effect, but known also by many other wonderful experiments that within the last thirty years had enlarged our knowledge of light in a marvellous degree. Invisible rays of light falling upon a certain kind of glass—glass tinged with uranium metal, chameleon glass—gave to it, in the absence of all other rays, a mysterious altered colour, revealing in that way their presence. The discovery with regard to uranium was made by Prosessor Stokes, and the property was designated fluorescence. It had since been discovered that fluorescence and phosphorescence were continuous—were extremes of the same phenomenon. But there were other rays which we did not perceive by our sense of heat, and which we called heat rays. It should be remembered, however, that the rays which we called light had heating effects. Radial heat and light were one and indivisible. They were not two things, but were identical. Take a black-hot kettle into a dark room and look at it. They could not see it; but let them hold it near their face, and they would receive it by what Bunyan had called "Feel Gate." Put the black-hot kettle near the eye, and the eye perceived it—they perceived it but they did not see it. To define light:—

What they perceived was light, if they saw it as light, and if they did not see it, it was not light. Radiant heat was light if they saw it. That meant that radiant heat had differences of quality—there was radiant heat that they could see, and radiant heat. When was radiant heat light? When the frequency of its vibrations was between 40 million millions per second and 800 million millions per second. When its frequency was below 400 million millions it was not light, but was only invisible low radiant heat. When its frequency was more than 800 million millions per second it was not light, but became what they called the ultra violet rays, the actinic or photographic rays. The most subtle of their senses, perhaps, was sight, and next came smell and taste. Prof. Stokes recently said he would rather look upon taste and smell, and sight as being continuous, because they all dealt with molecular actions of matter. Prof. Stokes would rather couple those three together than he would couple either of them with the other sense. Perhaps they might know more in the future. Perhaps some of Darwin's sublime speculations might become realities to them, and they might perceive a cultivable retina all over the body. They had not done that yet, but Darwin's grand idea occurred to them as suggesting that there might be an absolute continuity between the preception of radiant heat by the retina and its preception by the sense of heat. They must be content for the present to make a distinction between the sense of light and the sense of heat. With regard to the sixth sense, that of force, he had been vehemently attacked. The physiologists had very strenuously resisted admitting that the sense of roughness was the same as the muscular sense which was experienced by a person feeling his way in the dark, and bringing his hand into contact with some obstacle. The latter was undoubtedly a sense of force, but so also, he contended, was the sense of roughness and smoothness which were experienced in feeling a piece of glass or a lump of sugar between the finger and thumb. The latter had been called by the physiologists the "tactile" sense, but that term did not much enlighten them, since tactile simply meant belonging to touch. The perception of roughness was equally a preception of force with that which had been called the muscular sense, only, instead of the place of application of the force being distant, it was distributed over ten or a hundred thousand little areas.

PENNY SCIENCE LECTURES AT THE "VIC."

THE first of a series of popular lectures on scientific subjects, delivered under the auspices of the Gilchrist Trust, was given at the Royal Victoria Coffee Hall, Waterloo-road, S.E., on Tuesday week. Mr. W. Lant Carpenter, F.C.S., was the lecturer, and had selected as his subject for that and the following Tuesday evening "Ice, Water, and Steam." Numerous brilliant experiments were performed, and were alternated with representations of natural scenery, snow and ice crystals, &c., thrown upon a screen by the oxy-hydrogen lantern. By these means, and the use by the lecturer of familiar terms and a popular style, the interest of the numerous audience was well sustained throughout the evening, and was demonstrated by the applause which greeted the experiments, which passed off without a single hitch.

Mr. Carpenter said that his subject was water, in its threefold conditions of "Ice, Water, and Steam," or its solid, liquid, and gaseous states. He proposed to treat it that evening from a chemical point of view, and on the following Tuesday from a physical point of view. All simple forms of matter resembled water in their capacity to assume these three states; the heaviest metals and the lightest gases could exist either as solids, liquids, and gases, and the condition in which they appeared was but a question of relative compression and temperature to which they were exposed. Even hydrogen, the lightest of all gases, had within the past two or three years been demonstrated by M. Pictet, of Geneva, to have a liquid, and, consequently, a solid form, under extreme pressure and cold. There were about 70 simple substances, *i.e.*, substances which could not be resolved into other more elementary forms; they included the metals and certain gases and other substances, and no alterations had been made in the list for three-quarters of a century. Water was not one of these "elements," but, as Cavendish showed in 1781, was a compound of two gases, oxygen and hydrogen. Its composition was one of the most certain facts in the whole range of chemical knowledge; we could prove it in many ways, and could both reduce water to its elements, and reconstitute it from those elements, as he should be able to demonstrate. In whichever state we found it, the composition was precisely the same. Having exhibited magnified drawings of snow crystals, he showed that all the beautiful figures they displayed were based upon six-sided forms, and these hexagonal forms also existed as crystalline prisms in blocks of ice, as Prof. Tyndall had shown by passing a beam of electric light through masses of ice. The hexagonal construction was a characteristic of the crystallisation of water, just as the cubical form characterised common salt. Returning to the subject of the composition of water, the lecturer showed that an easy way of proving its compound nature was to place the wires of an electric battery in a vessel of water, when bubbles were given off and the water slowly diminished. These bubbles, if collected and examined, would be found to consist of oxygen and hydrogen gases in never-varying proportions as to relative volume and weight, and possessing each very different qualities. If weighed, they would be found to be in 18 parts, 16 parts of oxygen and 2 of hydrogen; if measured, hydrogen represented two volumes and oxygen one, which, when combined as water were so condensed as to form but two volumes. When the water was converted into steam the relative proportions remained precisely the same; but its bulk was so augmented that a cubic inch of water nearly filled as steam a cubic foot of space. Oxygen was that element which sustained life and combustion, and constituted, as they had seen, eight-ninths by weight and one-third by volume of water. By numerous experiments with ignited tapers, sulphur, phosphorus, steel springs, &c., Mr. Carpenter showed that while substances burnt rapidly and brilliantly in a vessel filled with oxygen, the gas itself could not be ignited. That substances burned in proportion to their affinity for oxygen, and that the facility of burning was proportional to the extent of surface exposed, were facts demonstrated by numerous experiments, even lead when finely levigated burning by simply throwing it down as powder. This explained the cause of spontaneous combustion in neglected heaps of oily cotton waste, and other finely divided substances: they slowly absorbed oxygen from the air, and at length burst into flame. Hydrogen gas was very different in many of its properties. Its most remarkable feature was its extreme lightness, its weight, volume for volume, being 14 times less than air—a property utilised in raising balloons. Unlike oxygen, hydrogen burned freely; but as the audience could see, a taper was at once extinguished when put into a vessel containing this gas. The water in a shallow vessel could be decomposed into its gases not only by electrical current, but also by dropping into it, as was shown, pieces of the metal potassium, which at once seized on the oxygen and ignited, burning up the hydrogen. Or the two gases, when mixed in proper proportions in a tube, could be reunited; but for this, heat was required to start the action. Having brought such a tube near a gas jet, a loud report was heard, and the lecturer remarked that the inner surface of the tube, although previously dry, would be found bedewed with moisture. The uniting of the two gases was always attended with a violent report. Colliery explosions resulted from the impure hydrogen given out from the coal seams uniting with the oxygen in the air of the mine when a light was brought to it. They were prevented by keeping the light from direct contact with the hydrogen in the mine. When a jet of hydrogen gas—the common gas in our mains was for practical purposes hydrogen mixed with carbon, and would illustrate the point—was fed by an inner jet of oxygen gas, and ignited, it burned with intense heat. This was utilised for fusing metals—Mr. Carpenter melted and burned some steel springs in this combined jet—and also for the production of the oxy-hydrogen light by which the views had been shown that evening, a cylinder of lime being so placed that the flame rendered it white hot. This was shown on a smaller scale on the platform. Passing on to another feature in the composition of water, the lecturer explained that the difference between hard and soft water resulted from the greater chemical impurity of the former, which held lime and magnesia and other salts. For dietetic purposes the hard water was preferable, and more palatable, but for washing it was less suitable on account of the waste of soap. It could easily be softened—a ready mode being to put soda in it. Where there was doubt as to the healthiness of water, it should be filtered. This would remove all matters held in suspension in the water and aërated it, but had no effect upon those matters dissolved in it. The chief danger in water was liability to contamination by the admixture of sewage. This impurity could be entirely removed by filtering or even boiling—an excellent precaution, but could be detected in a ready manner, as was shown, by pouring into a glass of water a few drops of permanganate of potash—"Condy's fluid." If the water were free from organic impurity it would retain its characteristic and beautiful tint of reddish purple for many days, but if polluted with sewage it would quickly fade to a dirty brown colour, the period occupied by the change exactly measuring the degree of impurity. The lecture was closed by the performance of some other experiments amidst continued applause.

RELATIVE EXPOSURE WITH VARIOUS DIAPHRAGMS.*

DIAPHRAGMS, or central stops as they are frequently styled, are used for increasing the sharpness of a picture which combines near and distant objects at the margin. I will not attempt to explain everything about diaphragms in the compass of a few lines; on the contrary, the instruction will be brief and rudimentary. In the use of diaphragms do not select one of lesser aperture than can safely be adopted to produce the result—sharpness. Suppose for a test that we have tried the second stop of a Morrison wide-angle view lens of eight-inch back focus, and found that the proper time of exposure for the Beebe plate is three seconds; now the novice naturally desires to learn what relation the several diaphragms hold to each other so that he may be guided, in making exposures, to have them of proper relative duration. Be guided by the following rule: As the square of the diameter of the aperture of one stop is to the square of the diameter of the opening of the other stop, so is the length of exposure given with the first to the duration of exposure with the second.

Example:—With the lens previously mentioned and the same brand of dry plates, using the third smallest stop, the diameter of which is $\frac{25}{100}$ of inch, we found the suitable time of exposing to be three seconds. Required the time of exposure using the next larger stop, which has a diameter in the opening of $\frac{35}{100}$ of an inch: 25 squared = 625; 35 squared = 1,225, a proportion of nearly 1 to 2; therefore the diaphragm of $\frac{35}{100}$ opening will require an exposure of the plate of 3 seconds divided by 2. Result, 1½ seconds.

Problem:—If the opening $\frac{25}{100}$ requires 3 seconds, what, with the same lens, will an opening $\frac{45}{100}$ demand? 25 squared = 625; 45 squared = 2,025, a proportion of about 1 to 3¼; 3 seconds divided by 3¼, gives a result of a trifle less than 1 second.

ABSTRACTS OF REPORTS, PAPERS, &c.

Protoplasm and the Cell Wall.

MR. W. GARDNER read a paper on "The continuity of protoplasm through the walls of vegetable cells." As the result of his investigations of some fifty species of palms, and typical representatives of other orders of plants, he found that the cells were placed in communication with one another by means of delicate threads passing through the walls of the cells. After alluding to experiments by other investigators, he said there had been all along an accumulation of evidence giving more and more weight to the idea of the unity of the individual and the working together of its various specialised organs. The investigation showed that in each separate cell the relation between cell-wall and protoplasm was one of a closer kind than had been hitherto imagined. In every single property of protoplasm, and in the exhibition of every phenomena, the plant and the animal were shown to be possessed of a common life; and now the statement that in animal life there was a differentiation of the protoplasm, while in the plant there was only one of cell wall, could no longer be held. They were now in a position to get a clearer insight into such phenomena as the downward movement of a sensitive leaf upon stimulation; of the wonderful action of a germinating embryo on the endosperm cells, even on those which were most remote from it; of the action of a tendril towards its support; and of a series of phenomena in connection with general cell mechanism too numerous to mention.—Papers were also contributed on "The Relations of Protoplasm and Cell Wall," by Mr. F. O. Bower; on "Protoplasmic Continuity in the Florideæ," by Dr. T. Hicks; and on "The Intercellular Connection of Protoplasts," by Professor W. Hilhouse. The latter gentleman concluded that protoplastic threads connecting neighbouring protoplasts are present in such widely different and diffused structures as sieve tubes, leaf pulvinus, the pith of resting leaf-bud, and endosperm of seeds; that in the contraction of the protoplast in natural plasmolysis these threads would normally remain unbroken; and that they may serve to transmit impulses from one cell to another, acting in this way somewhat like a nervous system.—Dr. Carpenter expressed the very deep interest with which he had listened to those communications, because they went to the very fundamental conception of life that they had been gradually coming to from the days when he was taught that cells were everything. They had been coming to perceive that there are a great many forms of animal and vegetable life which never arrive at the dignity of cell form. There are forms in which there is simply a continuity of animal protoplasm, and they had been generally coming to that idea in vegetable structure. This continuity of protoplasm was really just drawing the lower forms of the two kingdoms into closer approximation one with the other. These investigations illustrated the large general views to which they were coming of the fundamental conception of life, and, on the other hand, they showed the superiority of the modern method of microscopic investigation over the old method.

Chemistry in Elementary Schools.

Mr. W. Lant-Carpenter contributed a paper on "The Teaching of Chemistry in Elementary Schools." At a recent meeting of the Physical Society he brought forward the system of science demonstration in elementary schools as practised now for some years in Liverpool and Birmingham. The essence of his system was the employment of a specially-appointed expert, who should go from school to school with his apparatus, repeating the same lesson in each. The lessons were oral, no text-books were used, and the pupils wrote notes, which were revised by the demonstrator. In Birmingham a very good central laboratory had recently been erected, where the stock of apparatus necessary for the lessons in elementary physics was kept, and it had also been fitted up for instruction of a somewhat more advanced character in physics and chemistry. A good deal of useful work had already been done by the advanced pupils and some of the teachers, under the supervision of the senior demonstrator, Mr. W. Jerome Harrison, F.G.S. Mr. Harrison had lately commenced a general system of instruction in chemistry analogous to that in physics, since chemistry for the first time now formed a part of the Government code. His idea of the proper system, however, was (1) attendance of the pupils at a cou of elementary schools, well illustrated with *viva* examinations at the commencement of each le upon the subject of the preceding one; (2) a se course consisting alternately of lectures and ex mental work, the pupil in the latter perform himself the experiments given in the forme two courses to be confined to the common elements and their compounds); (3) a third course, mainly experimental, and occupied more or less with the analysis of simple substances. As at present with physics, the first of these courses would not be entered upon until the pupil had passed the fourth standard in the three R's. Great importance was attached by Mr. Harrison to the full reproduction of lectures in notes, illustrated by rough sketches of apparatus, &c.

Astronomical Observations at High Altitudes.

A note on some recent astronomical observations at high elevations on the Andes was contributed by Mr. Ralph Copeland, Ph.D. He gave an account of some astronomical experiments made at various heights in Peru and Bolivia during the first half of the year 1883 at the cost of Earl Crawford. At La Paz (elevation 12,000ft.), the author saw stars with the naked eye, in spite of the light of the full moon, that are with difficulty seen in Europe with artificial aid. At Puno (12,500ft.), Canopus, Sirius, and Jupiter were visible to unaided vision from one to twenty-five minutes before sunset. A number of small planetary nebulæ and stars, with very remarkable spectra, were found in the southern part of the Milky Way, by searching with a prism attached to a 6in. telescope on Professor Pickering's plan. The most remarkable stars showed spectra of little more than two bright lines, one near D, and one beyond F, with a wave length of 467mm., which the author, in conjunction with Mr. Lohse, had observed in the spectra of various nebulæ; γ Argûs is a star of this type, with the addition that the line near D is three-fold. Several close double stars were discovered. At Vincocaya (14,360ft.) the solar spectrum was very much increased in brightness at the violet end. The solar prominences were seen with nearly equal ease in C, D_3, F, and Hγ. With a small spectroscope a number of lines were visible beyond H and H_2. The solar corona was not seen, nor were any lines discernible in the spectrum of the zodiacal light, although that light was sufficiently bright to be very obvious when the moon was eight days old. At Arequipa (7,500ft.) the relative humidity of the air was as low as 20 per cent., and not much higher at other stations. The author believed that an observatory might be maintained with great facility at a height of between 9,000ft. and 12,000ft., the night temperature being little below the freezing point at any season. Beyond that height an increased elevation of 150ft. roughly corresponded to a fall of the thermometer of 1° F., and a depression of the barometer of $\frac{1}{10}$in., so that at 15,000ft. very arduous winter conditions were encountered. The author thought, however, that in the early summer an experimental station might be maintained for a few weeks as high as 18,500ft. Pieces of apparatus two tons in weight could readily be transported to any of the stations up to 14,360ft.

Report on Underground Waters.

Mr. C. E. De Rance presented the report on the underground waters of England and Wales, in which it was stated that much remained to be done in regard to the circulation of underground water, especially as to the influence of variation of barometrical pressure on the volume of springs. The proportion of the annual rainfall that was absorbed by different classes of rocks was a subject that also required further examination, the quantity of water a rock would yield being no measure of the quantity of water it was capable of yielding. More observations were required as to the action of faults in acting as ducts, along the face of which water was constantly passing. The facts already obtained pointed to faults offering no obstacle to the free passage of waters which, even if locally obstructed, invariably found their way through cracks extending across the width of the fault to faults traversing thick shales and clays of any age. Permeable rocks below the permanent water level might be regarded as reservoirs, the cubic contents of which was limited by the size of spaces between the grains and the width of the fissure and cracks by which the rock would be traversed.—Mr. Baldwin Latham, in the course of the discussion which followed, referred to the observations he had been making, and said he would be glad to pay for the services of observers who would undertake the watching of certain places now under his observation. The subject was a most important one, affecting the question of public health as well as public supply.

M. Janssen on the Solar Corona.

M. Janssen gave an account of his observations of the solar corona during the recent eclipse expedition to Caroline Island. The following is a translation of the substance of his remarks:—The effects, he said, might be due either to the sun or to the earth's atmosphere or to diffraction by the moon, or to a combination of all these, and it was a difficult matter to decide between them. In 1870 he had seen, for the first time, dark lines in the spectrum *of the corona—indicating, probably, the existence of matter capable of reflecting the solar light. This* observation had been confirmed by some observers, while others had failed to obtain evidence of it. M. Janssen wished to establish the point. He thought that the failure was due to the fact that the telescopes used by most observers had too small an aperture compared with their focal length, so that the amount of light received by the slit of the spectroscope was very small; the luminosity of the corona being very feeble. M. Janssen used a lens of 50 centimètres aperature, with a focal length of 150 centimètres to form the image on the slit of the spectroscope, which was one which admitted a large quantity of light. By means of an ingenious arrangement, it was possible to observe with one eye at the spectroscope, while the other noted through the finder the part of the corona examined. M. Janssen found a complicated spectrum with many dark lines. He also verified the fact that the light from the corona is strongly polarised, and came to the conclusion that the corona appeared to have a definite limit at no very great distance from the sun. He thought that the effect observed in some photographs, in which the corona appears unlimited in extent, was due to the length of the exposure adopted. In the course of his paper he referred to the measurement by photographic means of the intensity of light, and stated that the corona was about as bright as the full moon.

Geological Age of the North Atlantic.

Prof. E. Hull read a paper on this subject, in which he said:—From the comparisons made, the conclusion was drawn that when the lower Silurian beds were being formed the originating lands must have lain over the area of the Atlantic Ocean, that being the region towards which the strata swelled out on either hand, while the replacement of the sediments by limestone indicated the position of the contemporaneous oceans over Central Europe and Western America. In a similar manner, dealing with the carboniferous strata, he showed by a comparison of sections that over the American area the sedimentary strata swelled out in the direction of the Atlantic shore, while they thinned down or passed into limestones in another direction. From these and other considerations, he inferred that throughout the Archæan, the lower Silurian, and the Carboniferous epochs, the regions of North America on the one hand, and of the British, Irish, and Western Europe, were submerged, while a large part of the North Atlantic area existed as dry land, from the waste of which these great formations had been built up, and he urged that if such were the case the doctrine of the permanency of oceans and continents, as tested by the case of the North Atlantic, fell to the ground.—Dr. Carpenter said that the conclusion he had come to from the *Challenger* expedition was that the bulk of the sea below the present sea level was to the bulk of the land somewhere about 29 to one. He thought, taking the elevation of the different continents altogether, an elevation of 1,000ft. might be considered as about the average. On the other hand, the depression of the great oceanic area below the level of the sea might be stated at an average of about 13,000ft. The elevations of land which in any way approached the same height were ridges, and one of the most remarkable facts brought out by the *Challenger* research was that there was strong reason to believe that all oceanic islands were volcanic. In all their researches they found no indication of submerged land over these areas.—Professor Blake, in opposing Professor Hull's theory, observed that there was nothing to support the argument that limestones were necessary indications of deep water.

The V-shaped Reversible Griscom Motor.—A new form of the well-known Griscom motor, which is well deserving the attention of those interested in electric engines, has been recently introduced to this country. It is called the V-shaped from the fact that the field magnets take that form; but its special features of interest are that while nearly as powerful as the familiar barrel-shaped motor, it is considerably cheaper, and is fitted with a reversing motion, remarkably simple and efficient. The new motor has only one field coil, and weighs under 2lb.; it is thus specially adapted for use in model launches, and for other purposes in which it is desired to reverse the direction of the motion. The motor can be seen in action at 2, Scott's-yard, Bush-lane, Cannon-street, E.C., where Mr. C. R. Heap, the company's representative, has a bichromate battery specially adapted to domestic purposes, such as driving a sewing machine or a fret saw—the plates being lowered into the solution by pressure on a treadle, and automatically removed from contact with the liquid by raising the foot. By this means the speed of the machine can be regulated to a nicety. The motor, for its size, is probably the cheapest electric engine yet made.

AMERICAN milling machinists are doing their best to produce a good bran-compressing machine. A satisfactory machine for packing bran has not yet been produced.

SCIENTIFIC NEWS.

WE have received recently several Science Observer Special Circulars, the contents of which, having been telegraphed to Dun Echt, have generally been given in our columns previous to the arrival of the American mail. The Science Observer Special Circular No. 41, however, contains elements and ephemeris of Comet Pons-Brooks, calculated by Mr. S. C. Chandler, jun., the latter of which may be of use to observers. The comet detected by Mr. Brooks—at an exceptionally great distance, it may be mentioned—is, without doubt, the reappearance of Comet Pons, 1812, and MM. Schulhof and Bossert have made an approximate correction of perihelion to Jan. 25·824 Berlin mean time. Mr. Chandler gives Jan. 25·780 Greenwich mean time, and the following ephemeris:–

Greenwich midnight.	R. A. h. m. s.	N. Dec. ° ′
Oct. 26.	16 35 6	53 39·6
Nov. 11.	17 27 42	50 43·4
27.	18 19 10	47 23·8
Dec. 13.	19 37 16	41 39 8
29.	21 24 37	26 51·5
1884.		S. Dec.
Jan. 14.	23 12 47	1 10·2
30.	0 27 6	25 50·3
Feb. 15.	1 10 54	39 56·6

The brightness at discovery being taken as unity, on Jan. 14 it will be 117·81, about which time the comet will be distant from the earth some sixty million miles, and will be visible to the naked eye probably towards the end of December. The comet was first seen by Mr. Brooks on the night of Sept. 1.

The Gresham lectures on "Astronomy" will be delivered next week by the Rev. E. Ledger on Tuesday, Wednesday, Thursday, and Friday evenings at six o'clock. They will consist of a course on recent astronomy and sidereal astronomy.

On the afternoon of Sunday, Sept. 2, the sun was observed to look like a blue globe by observers stationed in the island of Trinidad.

Mr. J. Firth, writing from Huddersfield, says that about 9 p.m. on Oct. 6 he and several friends saw a splendid meteor, which seemed to emerge from the south side of the Pleiades, and assuming the appearance of a monster rocket passed through the constellations Aries and Pisces, and was lost near Beta Aquarii. The meteor passed through the chord of an arc 97° in length in about eight seconds, throwing off sparks during its whole course. It was a mixture of intense white and green in colour, and a portion of the track through which it passed was suffused with a deep-blue colour.

The death is announced of Prof. Oswald Heer, of Zurich, the distinguished palæontologist and botanist, who was born in 1809, and in 1834 went to Zurich and established himself as a privat-docent. Two years later he was appointed Professor of botany and entomology. His best known work is the "Urwelt des Schweiz," which has been translated into many languages.

Under the auspices of the Technological Industrial Museum of Vienna an international exhibition of tools and appliances used in connection with wood turning will be held in that city during the first three months of the year. The exhibits will include new methods of treating the wood by which its value is increased, and also novel specimens of wood turning. Applications should be sent in before the end of this month, addressed "Technologische Gewerbe Museum, 11, Eschenbachgasse, Wien, Austria." There will be no charge for space, and customs duties will be paid by the museum.

The Midland Railway Company have determined to adopt the Pintsch system of compressed oil-gas for lighting their coaches.

The idea of connecting the Isle of Wight to the mainland by means of a tunnel is resuscitated, and it is proposed to utilise the machinery employed in the preliminary works of the Channel Tunnel.

The Zuyder Zee was recently the scene of some experiments with Holmes's siren fog-horn, to test the suitability of the apparatus for signalling by the Morse code at sea. The experiments were considered satisfactory in every way, and demonstrate the possibility of communicating by means of sound signals between ships at sea.

Capt. Urquhart, of the s.s. *Cumberland*, reports that on a recent voyage from Copenhagen to Leith he placed bags of oil over the bows—presumably in such a way that the oil would filter through—and the result was that the waves were immediately rendered comparatively harmless. The vessel had 215 head of cattle on board, and it was important to make as much headway as possible against the storm.

The manager of the chinchona plantations of Bengal, Dr. King, in his last report, states that the process of shaving the bark of the Succirubra trees has been tried in the Sikkim plantations with good results. The bark renews rather slowly; but analysis shows that the shavings are rich in quinine and chinchonidine. Where red bark trees flourish and their health and vigour can be depended on for a long series of years, the shaving process Dr. King thinks will be a very excellent one.

The *Kingston Gleaner* reports the death at Mt. Prospect, Jamaica, of a resident at the ripe age of 125 years.

The United States circumpolar observing party from Cape Barrow have arrived at San Francisco. Lieut. Ray reports that all the observations required were made.

The largest organ probably ever constructed was lately completed at Ludwigsburg, says the *Times*. It is destined for the cathedral church at Riga. There are in it 7,000 pipes, 124 stops, with pedals, &c., proportionately numerous. A very complete "swell" arrangement allows the increase and diminution of sound to be effected with singular perfection and delicacy of effects. The filling of the pipes could not be carried out by organ blowers, but is effected by machinery worked by a gas engine of 4 horse-power. The organ is 20 mètres high, 11 broad, and 10 deep (about 65½ft., 36ft., and 33ft. respectively). The largest wooden pipe is 10 mètres (32¾ft.) high, and its cubic contents are 70·6 cubic feet; while the smallest pipe is only a centimètre and a half high (little more than half an inch), and is attached to the greatest one. By referring to p. 524, Vol. XXX., it will be seen that the large electric organ at Garden City, Long Island, contains 7,031 pipes and 115 speaking stops; but as that instrument is distributed in four parts of the cathedral, we suppose the Riga organ will henceforth rank as the largest in the world.

American Machinery and Tools.—Churchill and Co., of Cross-street, Finsbury, E.C., have issued a new catalogue of American machinery and tools, illustrating the manufactures of more than 130 firms. The catalogue is really a useful volume, consisting of 206 quarto pages full of illustrations of various machines and tools of more or less interest to everybody, but of special interest to those of our readers who write to ask where machines or tools to do this or that can be purchased.

Weight of Timber.—The following is the weight of seasoned timber per cubic foot, in pounds:—Apple tree, 49; ash, 50; bay-tree, 50; beach, 51; birch, 48; box, 60; cedar, American, 30; Lebanon, 35; cherry tree, 42; chestnut, 40; cork, 15; ebony, Indian, 70; American, 80; elder, 42; elm, 39; fir, Dantzic, 35; Memel, 38; hazel, 40; hornbeam, 48; larch, 35; lignum-vitæ, 70; logwood, 55; mahogany, Honduras, 40; Spanish, 55; maple, 47; oak, English, 50; American, 47; Baltic, 46; pine, red, 40; yellow, 33; poplar, white Spanish, 32; sycamore, 37; teak, Indian, 41; Moulmein, 45; Johore, 70; African, 60; wainscot, Riga, 38; walnut, American, 35; Spanish, 43; willow, 30; yew, 50.

New Clock at Washington.—A clock of peculiar construction has been manufactured for the United States Signal Service Bureau at Washington. The case is of brass, and allows the swing of a pendulum 39in. long; it is air tight, and admits of the air being exhausted, and the movements run in a vacuum, thus obviating any possibility of variation due to atmospheric changes. An electrical attachment is connected with the movements, by means of which the clock is wound as it runs, so that there is not the usual liability to variation arising from the differing conditions of the mainspring. This is accomplished by alternately breaking and closing an electric current. The motion thus obtained and the power of the current are used to re-wind the spring by means of a worm and other mechanism. The winding keeps exact pace with the running, and the slightest deviation from this standard is shown on an indicator. The train is jewelled, and is therefore little affected by friction.

LETTERS TO THE EDITOR.

[*We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.*]

All communications should be addressed to the Editor *of the* English Mechanic, 31, *Tavistock-street, Covent-garden, W.C.*

All Cheques and Post-office Orders to be made payable to J. Passmore Edwards.

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original."
—*Montaigne's Essays.*

DAYLIGHT OBSERVATIONS OF STARS — PRACTICAL WORK AND THE LIVERPOOL ASTRONOMICAL SOCIETY — "THOUGHT READING" — LOW BAROMETER — "A HEAVY BLOW, AND GREAT DISCOURAGEMENT" — MEASURING THE SLOPE OF HILLS—CLOUDY OBJECT GLASS —ROMSEY OBSERVATORY—SEEING THE SUN IN A POCKET TELESCOPE —CENTRE OF GRAVITY OF THE EARTH AND MOON — ANOTHER QUACK ADVERTISEMENT — THE SELENOGRAPHICAL SOCIETY—SIN AND DEATH—SHAKESPEARE AND THE STARS.

[21898.]—Will Mr. Franks (letter 21851, p. 86,) forgive me for saying that I put no "construction upon his daylight observations of stars" beyond that of the implication that they were very interesting; and that I merely pointed out that they were capable of repetition, to some extent, with very much smaller instruments than his, as an encouragement to young observers to follow his excellent example?

And, apropos of young observers, I am sincerely gratified to learn from Mr. Espin's letter (21855, p. 86,) what excellent work is being done by the Liverpool Astronomical Society, and how effectively that Association is working in directing the energies of its members into profitable channels. The amount of telescope power running to waste in this country is pitiable; and every astronomer must welcome such well-directed efforts to utilise it, and wish godspeed to those who are, however unassumingly, doing such good service to science.

As "Sigma" (letter 21856, p. 87) is so indignant with "Kappa" for the assumption that a trick may possibly have been performed on Mr. Carter, perhaps he will excuse me if I narrate a simple personal experience of my own in a cognate matter. A good many years ago I was considerably struck with an exhibition of (what was absurdly misnamed) "electro-biology." The operator invited members of the audience to subject themselves to the influence which he exerted, or professed to exert; and such as volunteered to do so were ranged on a platform, and, each one seated in a chair, were charged to maintain rigid silence and gaze intently at a coin or disc. After this had gone on for some minutes, the "electro-biologist" made certain passes over the eyes and forehead of his subjects, and then seizing their hands successively, and looking them straight in the face, told each one that he had forgotten his own name. In more than one instance, the person so addressed declared that he was quite oblivious of his name; and these susceptible patients were set aside for further experiments of a like nature. I went to see this exhibition more than once, and certainly had my faith slightly shaken by the reappearance upon the platform of the faces of certain youths whom I had previously seen under the "influence" of the lecturer. However, I saw—or thought I had seen—enough to render the matter worthy of serious investigation, so I commenced to experiment myself. I rather failed to reproduce the marvels of the exhibitor, but I did find one subject, a bright boy of some 11 or 12 years old, upon whom my operations produced a remarkable effect. "You cannot," I asserted, in the orthodox fashion—"you cannot remember your own name." "Well," was the response, "it is a most wonderful thing; I never forgot my name before in my life, but I cannot remember it now!" Much impressed with such a result, obtained upon a relation of my own, whom I, of course, knew intimately well, I continued my experiments, and finally, taking a silver-gilt filagree paper-weight, I threw it along the floor, and exclaimed, "N——, that is a toad?" "No!" was the instant reply, "it is not: it is a frog—I saw it 'jump.'" After my subject grew up he left England, and for some years I used to quote his case as one affording unimpeachable testimony to the reality of the phenomena I had witnessed. I never believed that I had had any further share in the matter than that of persuading the lad that my manipulations had produced an abnormal intellectual condition in him; and that he was in fact in a self-induced semi-hypnotic state; but I *did* believe sincerely that he was in such a state. Well, when we met on his return home, we naturally discussed old times, and among other reminiscences I revived was that of our bygone experiment in "Electro-biology." "Do you remember my making you forget your name, and take a paper-weight for a frog?" I asked. "Perfectly!" was the answer. "I remember the whole thing: *but I was only humbugging you all the time.*" Now this was no boy taken out of the streets at eighteenpence a night to perform on a platform, but a young English gentleman, whose pedigree may be read in "Burke"; and, therefore to appeal to mere "respectability" or social position, as affording a guarantee against deception in such a matter, is simply idle. The fact is that young people regard it as great fun to take in their elders, and "thought reading" and the like as a pious fraud to be legitimately committed for the sake of amusement. Moreover, the love of admiration and approbation is so innate in all girls, that they will do anything which does not involve an outrage on their modesty to win it. As far as I have been able to test the evidence advanced to support the idea that thought reading (in any legitimate sense) is possible, I am fain to confess that the Scottish verdict of "Not Proven" represents the result of my investigation in its most favourable possible aspect.

Let me thank "T. R." (letter 21869, p. 90) for his interesting record of a most abnormally low reading of the barometer. I am far enough away at this moment from my meteorological records; but on my return shall look curiously at that for January 19th, 1873, to see whether the atmospheric pressure at my station in any way approached that recorded by your correspondent.

I have some idea that it was in the tornado the description of which "Nun. Dor." extracts from the *Scientific American* (in Reply 50765, p. 91) that the Yankee sailors "stood in single file holdin' each other's hair on—only the hindermost critter was bald, and so didn't need it!"

"Far" (query 51800, p. 96) wants some simple form of clinometer. I fancy—but am not sure—that he can get what he wants at Buck's, the great tool makers, on Holborn Viaduct, London.

I do not suppose that the crown and flint lenses of "H. C.'s" object glass (query 51809, p. 96), were ever cemented together. It is quite unusual to cement the objectives of astronomical telescopes. He may try cleaning with a little pure alcohol on a cotton wool pad, and drying them with perfectly clean washleather, taking particular care to replace them in the position they originally occupied and with the same faces in apposition. Should the spirits of wine fail, he must send them to an optician to be repolished.

It is very difficult to answer query 51815, p. 96, without more data than "T. R." gives. Had he not better make a drawing to scale of his telescope and mounting, and surround it with an outline building? Allow, at least, 18in. clear between its walls and the eye end of the telescope, and 6in. from that part of the dome to which the dewcap approaches most nearly when the telescope is turned round on either of its axes.

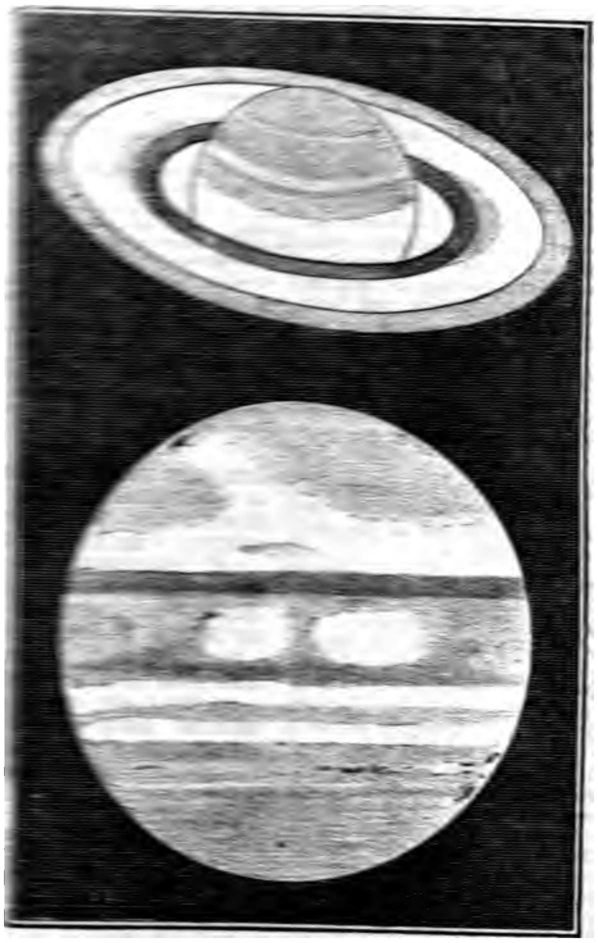
"Warragul" (query 51855, p. 97,) should take his telescope to the makers, and get them to put him on a very dark "London smoke" eyecap. Then he will be able to perceive some of the larger sunspots, should there be any on the sun.

Writing some 217 miles as the crow flies from my own library, I cannot answer query 51861 (p. 97) off hand. If, though, "P." will hunt through your last volume, I am sure that he will find that I gave the distance he asks for not very long ago in one of my letters.

It needs no ghost to rise from the grave to indicate the member of the Brompton Mutual Admiration Society (Limited), who penned the *Times* paragraph anent the reduction by Dr. Schuster "to a decimal point" of "the exact constitution of the Sun." "Scientific News," p. 105). Doubtless, we shall soon have Dr. S. himself proclaiming in print that the "non-elementary character of the elements has been irrefragably shown by that eminent astronomer (!) Smith," and so on. One hardly knows whether to feel pity, contempt, or indignation at the conduct of the (grossly miscalled) "leading journal," in lending its columns to this most impudent and persistent system of quack advertising.

I have a notion, well or ill founded, which I may mention in connection with letter 21878 (p. 106), that the Selenographical Society has collapsed altogether. I fancy that it expired soon after doubling its annual subscription.

[illegible]



[illegible] W. S. Franks.

JUPITER WITHOUT HIS SATELLITES.

[illegible] A letter on this subject from the [illegible] the morning of the [illegible] off the disc of the planet; the [illegible] See [illegible]

G. J. W.

THE RED SPOT ON JUPITER.

[illegible] our old friend, the red spot [illegible] is probably the most interesting stage of its existence. On the reappearance of the planet after its conjunction with the sun, the spot was somewhat anxiously watched for here, but owing to bad weather nothing decisive could be ascertained of its existence until the morning of August [illegible], when the spot was distinctly visible, [illegible] extreme faintness, and at times even a [illegible] could be made out. It was estimated [illegible] the central meridian at [illegible]. On the same morning it was also seen at Bristol by Mr. W. F. [illegible], and estimated central at [illegible]h. 48m., there being thus only a difference of one minute between the two times.

The red spot was next observed on Aug. 26th, when at [illegible] it was seen distinctly, though very faintly, several times near, and almost up to, the preceding limb of the planet. On the morning of Sept. [illegible], Sig. A. Ricco, of the Palermo Observatory, failed to detect any signs of the spot, the place where it formerly was appearing very white. It was, however, again seen here on the central meridian on Sept. 14th at 15h., my note saying:—"The spot is by no means so very faint or difficult [illegible] when the spot would be visible in England, and at [illegible] it was estimated to be on the centre. [illegible] was very good, better than on the 14th, [illegible] the spot was then described as "excessively faint and [illegible] rarely visible distinctly in outline, and its colour, too, is scarcely at all apparent." [illegible] has not since been examined here when the spot would be visible on the disc. The red spot would therefore now appear to be in the last stage of its existence, as a visible object, and deserving of the most careful attention. It is to be hoped that some of our friends furnished with large apertures, with which it may still be visible for a considerable time longer, as my observations were only made with a 5½in. Calver and a power of [illegible], will look up this interesting object, so that we may get as complete a record as possible of the time and manner of its disappearance. Its position is well marked by the curious bay or indentation of the dark south equatorial double belt opposite the spot, and which still remains a striking and prominent feature of the planet. From Mr. Marth's ephemeris, the red spot may be expected on the centre at about the following times:—

TRANSFER OF THOUGHT.

[21903.]—First let me disabuse "Kappa" (21892, p. 110) of two delusions. He thinks I am on the road to spiritualism, and that I have only recently started. The experiments and observations I have described were commenced 22 years ago, and my mind fully made up at least 20 years. This is neither the first nor second discussion on this subject in which I have taken part in these pages. As to spiritualism, of course I am a spiritualist as opposed to the materialist; that is, I believe in the spiritual nature of man, and of all existence in fact. But as to what is no doubt meant—that is to say, the "medium" stuff—so far from my being on the way to it, I was, to some extent (owing to my mesmeric acquaintances) mixed up with it when it first was introduced in England, and I have all along maintained that gress was not made: it is, however, almost hopeless to expect the brake question to be settled until the bill which has been twice "shelved" in the House of Lords becomes law.

Clement E. Stretton.

Saxe-Coburg-street, Leicester, September 22nd.

THE PARKER-SMITH AUTOMATIC SCREW BRAKE.

[21922.]—I REGRET to see, considering his alleged impartial views on the brake question, Mr. Stretton is so unfavourably inclined to mechanical brakes. I am afraid few people will agree with him in his assertion that mechanical brakes have had their day, and must now give way to better inventions, though he omits to mention what they are. It is correct that the chain and Fay and Newall's brakes are gradually being discarded in place of more generally adopted systems, though whether there has been much gain in reliability or efficiency is not so certain. There are many great and urgent requirements in a continuous brake having regard to the usual and convenient methods of railway working, that the present forms of air and vacuum brakes do not possess. The Westinghouse Automatic brake no doubt has shown better stopping results, and quicker application than the vacuum systems. Though it is unquestionably an ingenious price of mechanism, when we consider that all its component parts—viz., reservoirs, main and auxiliary, triple valves, brake cylinders, pistons, cocks, &c., are subjected to a pressure of 80 to 100lb. on the square inch, and the careful supervision necessary to keep such intricate machinery in working order, we must be more than reminded that the *simplest* means of securing a result is the best. The method of applying the brake by *lowering* the pressure in the brake pipe, while admitting a more certain automatic action in the event of a train separating, is an arrangement liable to constitute an element of danger. Indeed, fatal accidents have occurred both at home and abroad through the brake suddenly applying itself without apparent reason, and resisting all attempts of the driver to move his train. This necessitates the release valves being opened to allow the air to escape from the brake cylinders, an operation which may take from 10 to 15 minutes. It will be seen that it is advisable for any railway company using this brake to have the block system rigidly enforced to reduce the possibility of collisions arising from this cause. Again it is possible for a driver to start his train without the knowledge that all the brake pipes on the coaches are properly coupled up and the taps turned. He may start in the belief that he has control over the ten vehicles composing his train, to discover, when there is an urgent necessity for a sharp pull-up, that the shunter has omitted to open the taps between the third and fourth carriages, and therefore two-thirds of the braking power is not available. It is true that this last defect was sought to be remedied by substituting valves in the couplings in place of the taps; the effect of coupling up the hose piping causing these valves to automatically open and close when uncoupled. They, however, were not found reliable, and those companies that had adopted them at once resorted to the old and present form of taps. It will be seen, therefore, that the difficulty still exists, and apparently can only be met by careful inspection and supervision. Though no doubt the Westinghouse brake has shown good results, as Mr. Stretton has frequently pointed out, your readers will readily perceive that there are several improvements required before it will fulfil (besides those of the Board of Trade) the conditions our engineers require of a continuous brake. In Mr. Parker-Smith's screw brake these difficulties are practically removed; a simple chain taking the place of the brake pipe, hose connections, and taps, it follows that nothing but the actual rupture of this chain would cause the brake to apply itself when not intended, and seeing that none of the braking pressure is transmitted through it, this contingency is hardly likely to occur. I have explained before how the automatic action in the event of a train separating is effected, and that to release the brake would merely require the chain to be tightened. In the second place, as the brake is normally *on*, the train at starting cannot be moved more than the distance represented between two or three revolutions of axle (about 30ft.), unless the brakes are taken off. This is of course a practical test that the brake is in working order throughout its entire length.

The vacuum systems employing for their braking force the unbalanced pressure of the atmosphere, the excessive strain on the apparatus imposed by the air pressure system is avoided. It has however the disadvantage of a slower brake action with heavier and somewhat cumbersome apparatus. A serious objection in most of the vacuum systems is also the fact that uncoupling the carriages for the purpose of shunting, &c., causes the application of the brakes, preventing the carriages being moved till the brakes have leaked off. This otherwise *inconvenient period* has been reduced to two minutes by providing a leak hole in the piston. Whether or not, in the event of a detached portion of a train being automatically pulled up on a heavy gradient, this period would be found sufficient to find and apply scotches to the wheels, as stated by the advocates of the system—is a question I would prefer leaving undisputed, than attempt to test it by personal experience.

With reference to the Heberlein brake mentioned by Mr. Stretton as having been tried on several railways and found, though received favourably in Germany and Switzerland, to be unsuitable to English railways, it is described as an automatic friction brake, permitting a steel friction wheel to fall against a chain to be wound round a drum, attached to and parallel with the steel friction wheel, pulling the brake-blocks against the wheels. In practice, however, it is found that all the brakes on a train do not come into action simultaneously, also, owing to the friction wheels skidding while the brake remains on, considerable wear and tear takes place. Another disadvantage is that the brake must be always fully on or off, and is therefore not easily regulated. From all these defects the automatic screw brake as designed by Mr. Parker-Smith is absolutely free. It is essentially a *mechanical* brake, and not a chain brake as many confound it with. The limit of graduation in a screw being undefinable, any desired braking pressure may be maintained for an unlimited period. Another important advantage is the very quick application that can be obtained by the screw brake. Less than three revolutions are sufficient to apply full braking power. It is stated by the advocates of the Westinghouse system that their brake can be applied in one and a quarter second. A train travelling at 60 miles per hour will advance in that time 110ft., whereas three revolutions of the axle means an advance of only 30ft. Mr. Stretton informs us that though many engineers have inspected the screw brake, none have as yet adopted it. Although I have made several inquiries, I am unable to find a single *practical* objection that can be sustained against it: in fact all those who have inspected it in an impartial manner, are struck with the ingenuity and perfection of the invention. I have heard that several of the Continental countries are arranging for its trial and adoption. A conference of Continental engineers not long since decided that after an exhaustive and extensive trial, the fluid systems were unsatisfactory. Nothing further will be done till a reliable mechanical brake is in the market. I think with "K. S. T.", page 64 (our Editor kindly permitting) if Mr. Parker-Smith would give us a sketch and description of his brake mechanism, &c., the readers of the "E. M." would be in a position to decide on the important question of continuous brakes.

Imprimatur.

MR. STURROCK'S STEAM TENDERS ON GREAT NORTHERN RAILWAY.

[21923.]—CORRESPONDENTS have once or twice asked for some information respecting the once celebrated steam tenders introduced by Mr. Archibald Sturrock when locomotive superintendent of the Great Northern Railway, and applied to the engines used in the heaviest goods traffic. None has, however, been forthcoming: so, as the subject is one of considerable engineering interest as an important experiment in locomotive practice, I venture now to send a few particulars, mostly obtained from a friend formerly in the locomotive department of the G.N.R.

It appears that, about the end of 1863, Mr. Sturrock determined to increase the capacity of his goods engines by adding a pair of cylinders to the tenders, and applying the power to the tender wheels. The engines were of the standard type then employed for goods traffic, having six wheels coupled, 5ft. diameter, and cylinders 16in. by 24in. One of the G.N. goods engines of this class, built by Wilson, of Leeds, is illustrated in Clark's "Railway Machinery." Several engines and tenders were accordingly altered at the company's works. The fireboxes were enlarged, a second regulator placed in the dome, and the feed pumps arranged for pumping hot water. The tenders were fitted each with a pair of cylinders 11in. diameter, with a stroke of 17in. The cylinders were placed between the first and second pairs of wheels, inside the frame plates, and all six wheels were coupled by outside cranks and side rods. There was also a kind of surface condenser in the tank, made of thirty 2in. tubes, for heating the feed water, which it did to boiling point very speedily. The first engine thus fitted was No. 391. It was set to work on the London-Peterborough division, and was soon followed by Nos. 393 and 394. These engines proved themselves capable of hauling 40 to 45 loaded coal waggons on the main line over ruling gradients of 1 in 200, and as many as 60 on the Lincolnshire line, which is nearly dead level, the loads for an ordinary engine being 30 and 35 respectively. This result was deemed so satisfactory, and the steam tenders appeared on the whole so successful, that the company determined on having 70 new engines built on the same system. They were constructed by several different makers, the contract price being £3,750 each. Their numbers were 400 to 469; they had 16in. cylinders on the engine and 12in. cylinders on the tender, each pair of cylinders driving six coupled wheels. The engine weighed 35 tons, and the tender 25 tons, in working order. A complete revolution had apparently set in in the working of goods traffic, and sanguine expectations were entertained as to the results.

Before, however, the whole of the 70 engines had been delivered, the company had reason to believe that all was not so satisfactory as it had seemed to be. Grave doubts were suggested as to the economic value of the steam tenders. The cost of repairs was found to be excessive, as, in addition to the dust knocked up by the engine proper, the sweepings, &c. of the footplate found their way into the tender-motion, thus causing extreme wear and tear. Unfortunately, too, they never received really fair play, for a dispute arose with the engine-drivers, who claimed an extra sixpence a day for working them, owing to the greatly-increased loads they drew. This demand was rejected by the directors, and then the men, in retaliation, systematically neglected and ill-used the engines, so that the repairs bill mounted up inordinately. An attempt was made to restore the equilibrium by distributing the extra expense over the locomotive stock generally; but this created dissatisfaction, and in the end the directors were forced to discontinue building the steam tenders; indeed, many of the 70 already mentioned as under contract were ordered to be stripped of their tender working gear before they left the builder's shops. In 1866 Mr. Sturrock resigned, and was succeeded by the present locomotive superintendent, Mr. Patrick Stirling, who soon "improved off the earth" every remaining steam tender, and rebuilt the engines with 18in. or 19in. cylinders.

Such I believe to be an accurate history of a very important experiment in locomotive engineering, and I hope it may be interesting to readers of the "E. M."

Wellington, N.Z., July 17. **C. R. M.**

REPLIES TO QUERIES.

◆

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[51203.]—**Music.**—I am obliged to Mr. W. J. Grey for his notice (p. 111) of my request; but I can only wonder what my departed ancestor would have said to such a reply. Can Mr. Grey point out in what way his use of organ stops "full to fifteenth," will produce consecutive fifths? Is there, for instance, a passage in the "Messiah"? Mr. Gray must forgive me, but he appears to have missed the point of my query, which, stated tersely, is, "What have the pitches of stops to do with harmony?" If Mr. W. J. Grey will analyse any given passage from the works of "my departed ancestor," using all the stops in the biggest organ ever made, he will find that there is nothing "wrong about the rules" of harmony, but some misconception at Elswick.—G. F. H.

[51203.]—**Music.**—Consecutive fifths are forbidden because they are not pleasing to the ear, as may readily be proved by trial and comparison with other intervals. Octaves are not unpleasing, but are forbidden in four-part harmony, as Richter says, because "the doubling of a note, although it adds one voice to the harmony, does not add any new interval to the chord," so that the effect of four parts is lost. Whole passages in octaves are common enough. On the organ we not only get consecutive octaves, which are not forbidden in this connection, but also fifths, and the most extraordinary conglomeration of notes when the twelfth, mixture, and sesqui-altera stops are drawn. For instance, the common chord of C gives in addition to the principal notes C E G, G G sharp B C D E, all sounding at once, and repeated several times over in different positions of the scales above the principal notes; yet the effect is good. To understand why, read the treatise of Helmholtz on "Harmonics," and on the cause of the different quality of tone in musical instruments, for instance, the flute, oboe, clarionet, or fiddle. When a note is sounded, the pipe or string not only vibrates as a whole, but also in several distinct portions, so that the note produced is not really a single note, but as it were a chord in which the principal note is sufficiently powerful above all the rest to prevent the harmonics, as they are called, being heard as notes, while the harmonics, by their relative number and position as to pitch, give the specific [illegible] to the instrument. By proper means, which we cannot discuss here, they can be heard and played on the scale in their several positions. A tuning-fork has very few, if any, harmonics, and its tone is sweet and pure, as it is called; an oboe has [illegible] harmonics. The harmonics of a pianoforte string can be heard by striking a note and allowing the sound to die away: as the principal note weakens, others will be faintly but distinctly heard. Now, the so-called mixture stops of an organ are for the purpose of adding such extra harmonics to those due to the foundation stops themselves as have been found in practice to produce a good effect. The discoveries of Helmholtz afford an explanation of the reason. These mixture stops can only be used with others loud enough to cover them; if used alone or with soft stops the noise is horrible. May I be allowed to remark that it might be well for us all, and especially for those who have the great advantage of being connected with science schools, to think that it may, after all, be possible that rules of long standing and universal acceptance are correct, even although we do not understand them and think "there is something wrong about them."—Emeritus.

[51203.]—**Music.**—Mr. W. J. Grey presumes that there must be "something wrong" about harmony rules concerning consecutive fifths and eighths, because he finds that by drawing certain stops on his organ such progressions are made with *very good result*. He does not consider the circumstances, however, which make the result satisfactory; but takes for granted that the consecutive intervals are of the *same nature* as those forbidden by the *established* rules of harmony. As a matter of fact, every musical sound that is produced gives out the intervals of an octave, a twelfth, a fifteenth, and innumerable other harmonics which become more and more feeble as their distance from the prime sound increases. The use of mutation and mixture stops is neither more nor less than an attempt to give greater power and brilliancy of tone by imitating the more important of these harmonics, and the satisfaction derived from their use depends upon the *amount of prominence* given to them. The study of harmony presume the parts to be of equal importance; and, under these circumstances, the ear is offended by consecutive fifths. Let the "composition pedal" teach Mr. Grey a lesson. Let him observe that, when it is pressed down four stops are in use besides the twelfth; so that the stop which is responsible for the forbidden fifths is (in *power*) equal only to about the fifth of the entire combination. Consecutive octaves forbidden by the rules of harmony and such octaves as are produced by combination of organ stops, are even more distinct from each other in their nature than the two kinds of consecutive fifths. If, however, these observations are sufficient to satisfy Mr. Grey that the rules of harmony concerning consecutive fifths have "nothing wrong" about them, he may, perhaps, feel convinced that it is possible for the laws of consecutive octaves also to be genuine, without going into them now. The answers (on which Mr. Grey commented) to the original question put some weeks ago, were all to the purpose. It is evident, from his comments, that Mr. Grey is not a musician, although he may have *read through* a work (perhaps, several) on harmony.—Teacher of Harmony.

[51253.]—**New Zealand.**—In answer to "Old Subscriber," I should recommend him to the north island, though not so far advanced as the south island, as the more agreeable climate. He should go to one of the larger towns, Wellington or Auckland for instance, where he is more likely to obtain the repairing jobs he prefers. As soon as possible on arrival, I should advise him to invest his £1,000 in two separate amounts on freehold mortgage security. This will bring him in some £80 to £100 per annum, and as living is cheap, will enable him to board comfortably during the period the mortgage is running, say 3 or 5 years. He would thus be enabled in the intervals of his repairing jobs, to look round and see the requirements of the colony; and by the time his capital is repaid will see how he may more advantageously invest it in the erection of small houses in a growing town. Many have done well in this way. The small houses are built entirely of wood with brick chimneys, one story high, and roofed with galvanised corrugated iron.—Imprimatur.

[51253.] — **New Zealand.** — In replying to "Engineer," I would personally select Auckland in preference to Otago, as the best place for an engine fitter. I am afraid my experience will not allow me to say whether a lady could establish a school for young children with success, though I see no reason why she should not in a large town. There is, however, a very complete system of state education, and in the smaller towns is attended by children of all classes, the fees being very light. As suggested to "Old Subscriber," I would not advise you at first to start any speculative building, but as you possess a knowledge of joinery, you would have no difficulty in procuring contracts. Ten per cent. can be safely got for sums of £200. If you go by sailing vessel, I should certainly recommend you to take all the clothes you can, though avoid any great excess of luggage. Cloths and tweeds are manufactured in N.Z., suits being sold at similar prices to England, but the quality is not so good. A good supply of moleskin trousers you will find very useful. N.Z. is considered a very healthy colony; notwithstanding the scarcity of doctors, the mortality is very low. As regards its suitability for neuralgic subjects, I don't think I ever met any, though, on reflection, that may be evidence that the colony *is* good for them. You might apply to the New Zealand Steam Shipping Co., for post of an assistant engineer; otherwise I don't think you can do much to employ your time on board ship, beyond making samll articles such as picture frames, &c., for your own use.—Imprimatur.

[51253.]—**New Zealand.**—I will preface the information I am (at considerable cost) able to give about N.Z., by stating that the whole population of this colony is somewhere about half a million, counting Maories and all. The whole of the land is mountainous and broken, with the exception of one or two plains of large extent. The soil in the northern parts is of the most worthless description, and fully justifies the remark made by Commodore Wilkes, of the U.S. Navy, "that the scientific expedition under his command left its sterile shores without regret." My remarks applying to the colony as a whole are founded on experience purchased in Auckland. First, as to climate, they plead guilty to 56in. of rainfall, while in the Thames valley we get about 23 or 24; and I never yet met with anyone here who wanted more. For nine months the showers are at short intervals, and for three the intense heat dries up the grass and cracks the sterile clay into deep fissures. In the winter the cold, bleak winds that howl and rage bring rains from either ocean, and those residents who have been there for a few years suffer as much from the cold as we are supposed to in England. The climate is so enervating from the excessive humidity and heat that they—i.e., the old identities, coddle their bodies up with wraps in weather that the average "new chum" thinks fairly warm, and it is difficult for a new chum to realise the undoubted fact that their sufferings are real and not make believe. As for wind, why it is *the* pest. No, we will say *one* of the pests of N.Z. The dull, lowering days of winter are made lively by the sub-tropical gales that do their best or worst to overturn your house, and houses (wooden ones) are rocked to that extent that the inmates are oftentimes afraid to go to sleep for fear of the momentarily expected overturn; brick houses are too expensive and *too damp* to be obtainable by middle-class folks. Shelter trees are about the first things planted by the squatter, and blue gums having had their day are being supplanted by pines; but I think unwisely, as gums, from the rapidity of their growth and the scent they exhale, are undoubtedly valuable trees in such a swampy land. The following extracts from a contemporary publication will perhaps be taken as an endorsement of facts I have stated:—"The wind is always blowing here. I don't think we have had a calm day since I landed. It is very unpleasant, but I think it makes the climate more healthy. The great number of marshes would cause fever and ague if the wind did not blow the miasma away." From the broken and mountainous character of the colony (regarded as a whole), it will never be more than a poor member of the Australian colonies. There are doubtless tracts of very fertile soil; but the majority is utterly unfit for the production of corn, and even grazing lands can only be *made* at enormous expense. The excessive rainfall so floods and supersaturates the soil, that the soluble salts which form the essential, and, indeed, vital portions of the food of economic plants, are washed out to sea, and ferns are the characteristic flora. Of useful timber trees the number is exceedingly limited; but in this respect New Zealand is in no worse plight than Australia. The timber of the Kauri pine is the one wood that is used for all joinery work, and as it has the peculiar gift of being able to shrink endways of the grain, and can and does twist and warp in a way to give an American joiner spasms, it is utterly unfit for indoor work except flooring; for weather boarding it answers well, and for rough outside work it forms an admirable timber, as also does the wood of the Puriri; good samples of which form almost indestructible house blocks; for sea piles the Totara is another splendid timber; but for joiner work none of the N.Z. "bush" is at all comparable with the pine timber of the northern world. This is a serious drawback to a country, as all wet-casks have to be imported. Kauri, from its cheapness, is, of course, used; but is a poor and expensive substitute. Another point against these woods is their weight, and panels of doors are made so thin that they give but slight protection. The larva of locusts and other pests destroy immense quantities of timber, as they bore into the trees to such an extent as to make the timber useless for other than firewood purposes. All plantations of fruit trees require careful and costly watching, in order to preserve them from these pests; and the variety and enormous numbers of insect plagues must (coupled with the bird nuisance) prove serious drawbacks to the farmer. I would most seriously warn any intending emigrant against trying to live out of agriculture in the northern districts; the mildness of the climate—of which so much is made—and its excessive humidity—so quietly ignored—form such fine times for both bird and insect life, that their increase is simply astonishing; and the poor sparrow comes in for any amount of objurgation from irate squatters. The mouse and the rat have also found such congenial quarters, that they also swarm all through the bush. In some districts it is the fern that ruins the farmer; in others, the rabbits and wild pigs are his foes, and if the pheasants, &c., increase much more, they also will prove similar curses to struggling cultivators of the soil. Home folks must consider that where so small an area of land is under cultivation, the isolated patches receive the visits of nearly all the inhabitants of the intervening bush when the crop is set, and again when it is ripening. From the *Auckland Star* I extract:—"*The Bird Nuisance.*—A meeting of the committee of the Auckland Agricultural and Pastoral Association was held this afternoon in the office of Mr. Percival (Secretary). The principal business of the meeting was the consideration of the question introduced at a previous meeting by Mr. Lamb, 'How to do away with the Bird Nuisance.' Several samples of grain were shown which had suffered very severely by their depredations—in fact, were rendered quite valueless. A sample of wheat from Mr. Wallis's farm was especially brought under notice." "*The Birds Again.*—Sir,—I should feel obliged if you, or any of the newspapers, or numerous advocates for the formation of orchards and vineries, and planting of fruit trees, would be so kind as to suggest how the fruit is to be protected from the ravages of birds, beasts, and insects, without incurring such an expense as to render it unprofitable. Hares and rabbits attack the bark of the stem and destroy the trees, shell snails and black leeches (which the birds never seem to molest) the leaves and shoots, and various birds consume the fruit. I don't think I have seen a safe cluster of grapes in my orchard since the introduction of birds, nor a safe berry in some of the bunches. Cherries, plums, figs, and other fruits seem to share a similar fate. I had a large and splendid crop of strawberries this year, which had been prepared with great care, but I didn't reap a single berry, the blackbirds and other vermin monopolising the whole as fast as they ripened; and if I attempted to raise grain am obliged to turn it into hay, owing to the sparrows requiring all the seed either when first sown or as the crop matures. The measures lately prepared by some farmers for the destruction of sparrows appear utterly inadequate for the purpose, and little else than a mockery. I recommended them some years ago to combine for their extermination and removal of Government restrictions, when their annihilation would have been more practicable than now. . . . . I perceive by an article in the *Herald* to-day, that an orchard in Nelson, comprising an acre and a half, that used to be very productive, has been completely swept by fruit-eating birds, not leaving a vestige of any kind, from apples to currants.—I am, &c., A Star Reader."—From the foregoing, some of the drawbacks not mentioned in official guides may be inferred; and should I be able to spare time, I will, with the Editor's permission, give other details; but at present I will conclude with one most instructive fact that, well and sufficiently considered, will show the impudence of those who brag and boast about their "Britain of the South." From our "Britain of the North," could a spectator be elevated to a sufficient height to see over half the world, he would view (nearly) the largest amount of land possible; from the Britain of the South he would command a similar extent of water. Now, any reflective person who understands what carriage costs, and how it determines the profit or loss of commercial transactions, will see how splendidly adapted a poor country must be for becoming a commercial centre, when isolated and cut off from all available markets, except at ruinous rates for freight that other and richer competing countries are exempt from.—London Stone.

[51481.]—**Optics (U.Q.)**—"Dubitans" is not required to believe all he reads.—Wm. John Grey, Elswick Science School.

[51495.]—**Polishing Stones, &c.**—Mr. E. Owen will find on p. 147, No. 656, a useful reply to his query, with an illustration of a lapidary's "lap." If, however, your correspondent can obtain Nos. 520, 527, and 535, he will find three letters, in which he ought to be able to read all necessary information to start him on "Lapidary's work."—Essar.

[51501.]—**Cotton Spinning.**—Purchase "The Practical Cotton Spinner," by W. Leigh, price 2s.; or "The Young Man's Assistant to Cotton Spinning," by A. Prestwigh, price 2s. 6d. Both works may be obtained from Mr. John Heywood, Manchester.—J. G.

[51510.]—**Excelsior Lime.**—I do not know this special lime; but good limes can be made out of stone lime. They should be cut with a saw, and be rounded up. See p. 155 last volume.—Essar.

[51520.]—**Granule Carbon Battery.**—Thanks to "Hugh" and "G. H. F." for their kind information. I have tried three cells of the above battery, charged according to instructions given, but sorry to say it is not a constant battery. The first night I tried it it was all that could be desired. The second night a little weaker; and the third night it would scarcely burn the carbon red of a 2½-candle lamp, and was never able to recover itself. I tried it again with fresh liquids, and adding mercury to each porous pot: the result was just the same, excepting the action on the zinc rods was not so great. Would some one kindly say if I have erred in any way, and if you would recommend multiplying the battery power or a small dynamo for lighting a small shop window that is cased all round, such as a shoemaker's window, and where gas would be of no use?—Nill.

[51528.]—**Insomnia.**—This querist cannot do better than read Dr. Edmunds's paper on the subject in No. 920, p. 226.—Essar.

[51530.]—**Fruit Stains on Flannel.**—Has Mr. Hannen read the paragraph on p. 454 last volume? It seems to me he will find something suitable there. —Essar.

[51537.]—**White Metal.**—The alloys used for the purpose mentioned by "Boswell" are rather numerous; but the following is a list which may be useful: 1. Copper, 80; tin, 18; zinc, 2. 2. Copper, 74; tin, 9·5; zinc, 9·5; lead, 7. (The latter frequently used for loco. brasses.) 3. Copper, 82; tin, 16; zinc, 2. 4. Copper, 56; zinc, 28; tin, 16. The latter, it will be seen, is cheaper; but good results have been obtained with copper, 5·5; zinc, 80; tin, 14·5. A white alloy to be cast directly into the boxes is—lead, 32; zinc, 18; antimony, 50. Perhaps the best is—copper, 4; tin, 96; antimony, 8. All the alloys containing copper and zinc are difficult to make. Usually, brass containing a definite quantity of zinc is taken, and added to pure copper previously melted; but the hard metal should always be melted first, and then, as soon as the zinc is ready, be poured into it, the other components added, stirred well, and cast at once. Keep the mixture covered with charcoal dust while mixing.—Nun. Dor.

[51546.]—**Magnets.**—Use a coil of copper wire—stout silk-covered best. Pass a current from a battery through it while at the centre of the bend, and then move it steadily along each limb, taking it well over the ends, but not off. Use a battery giving a powerful current, and pass the coil from end to end several times. A coil of four layers and half a dozen turns is quite large enough. Twist up on a mandrel larger than any bar you wish to magnetise, and tie the helices together with string. —Nun. Dor.

[51553.] — **Hardening Corkscrews.** — If "J. McD." hardens his corkscrews, he must temper them, or they will snap. There is no means of producing temper without the previous hardening.—Essar.

[51619.]—**Specific Gravity.**—I beg to thank "N. C. R." very much for his kind reply to my query. The first part of my question had special relation to solutions of sugar, nitrate of silver, and subcarbonate of soda, and if "N. C. R." can furnish me with a rule by which I can determine from the specific gravity of the solution the amount of any particular substance per gallon, or give me the title of any book treating on the subject, I shall be very grateful to him indeed.—J. R.

[51649.]—**Legal—Intestate.**—If Thos. Goodall has died intestate, leaving a brother or a sister, and children of a deceased brother or sister, then his money would be distributed, half to such surviving brother or sister, and the other half to be equally divided between the children of any deceased brother or sister.—Lex.

[51657.]—**Legal — Settlement.**—A., as the settler, cannot by any means undo this settlement. Such settlement is binding on her, and the trustees must see that the terms of the deed are properly carried out, the property being in trust by marriage for the children, and, in default of issue, for her nephews and nieces. In certain cases, where a mistake is made at the time by either party to which the other party is accessory, although such mistake may have been innocently made, a court of equity may set a settlement aside; but this is not applicable to your case, so A.'s" wish cannot be accomplished.—Lex.

[51659.] — **A Three-Cell Battery.** — Will "Electrician" kindly give me the proportions of ingredients used in the three-cell battery, also whether the ordinary electric-bell wire will answer the purpose, and how would you connect the wires to incandescent lamp? How many lamps will one three-cell battery work?—Norwood.

[51669.] — **Legal—Paving.**—Yes, the urban *authority* have such powers given them by 38 and *39 Vict. c. 55, sects. 149, 150, 153, 156,* and *158.* This last section gives them power by their bylaws to determine and fix a plan the proprietors are to follow, and in default of such notice being observed, the urban authority may do the work themselves, and charge the cost and expenses on the proprietor neglecting to observe such notice.—Lex.

[51682.]—**Legal — Will — Administration.**—No; the husband of the married sister has no claim on his wife's property left after the 1st January, 1883; it is hers solely and separately, and would remain so till she made a gift of it to her husband. Property in Ireland is governed by the Married Women's Property Act of 1882, applicable to England and Ireland, but not to Scotland.—Lex.

[51686.]—**Historical.**—"F.R.A.S." states that "there can be no doubt that Christianity was *introduced* into Britain in the year 597." He should have said *re-introduced*, for there were Christian bishops in Britain several hundred years before St. Augustine landed here. I may refer, as a proof of this, to Gildas, "Britannus Sapiens de Excidio Brit.," p. 23, and to Crakanthorpe "Defensio Eccl. Anglic.," p. 23, from which I give the translation of two short passages: "It is clear that our British Church was founded a few years before that of Rome." Again, "Learn that the Roman Church in Britain was not the mother, but the sister church, and a younger sister by about five years." Gildas states that the British Church was founded towards the close of the reign of Tiberius, who died A.D. 39. The Roman Church was founded in February, A.D. 55, as stated by Baronius. See also Bingham, "Antiquities," ix. 6, p. 20: "Indeed, it would appear that there were more bishops in England and Wales at the time of the Saxon invasion, 150 years before the arrival of Augustine, than there are at this day."—Otter.

[51690.]—**Metaphysics.**—The work I can best recommend is Max Muller's 2-vol. translation of "The Critic of Pure Reason," by the famous German philosopher, Emmanuel Kant. If "T. H." be thoroughly acquainted with the German language it would be well, but not better, to procure the original. Max Muller's excellent translation may be had on loan from Mudie's—Mufti.

[51716.]—**Street Lighting.**—The firms mentioned in your query turn out excellent articles. There are a great many different kinds of lamp-governors in the market, but they may be conveniently reduced to two classes: the older class having leather diaphragms, and the modern class having metallic pistons in place of leather diaphragms. The metallic governors are rapidly displacing the older form; they look much neater in the lanterns, and, from being considerably smaller in diameter, obstruct much less light than their elder brethren. Peebles' people turn out the smallest governor with a leather diaphragm that I know of, and it is furnished with a movable cap so that the weights for adjustment can be altered without taking the top off the instrument. I have tested a great number of them, and I find they are thoroughly reliable. The same firm also manufacture a metallic governor, called the "needle;" this, too, is a very good instrument, and will stand testing pretty roughly when new; but, as far as my experience goes, the metal of which they are constructed is too soft, consequently, after they have been in use a year or so the flange of the conical piston wears beyond the range of adjustment, and they are rendered useless; but this is a defect that could be easily remedied by manufacturing them in brass, instead of soft white metal. Sugg and Co. manufacture a leather diaphragm governor of improved form, in which, instead of adjusting by movable weights, as in the old form, the adjustment is made by a conical-pointed screw, thereby saving a lot of time and trouble in testing. They also make a governor with a metallic piston having grooves turned in its periphery, whereby a small quantity of oil is held by capillary attraction, thus rendering the piston gas-tight without friction. They have also recently introduced a small governor with a steatite bell or piston. This little governor is neat and reliable in its action, and looks well in the lantern; but it has this disadvantage—the bell is rather fragile, and will not bear a fall, and should it require cleaning from dust, I should think twice before I trusted it in the hands of an inexperienced man, such as lamplighters usually are; but if you have experienced fitters at your command to look after lamp fittings, then you could not use a better. Should you not be so happily blessed, then I cannot recommend a better governor than Borrodaile's. This is a neat and reliable little instrument, and will give satisfaction. Its only moving part consists of a brass disc; and you might safely set a man of average intelligence to clean it with a bit of wash-leather without fear of injury. I have submitted this governor to some rather severe tests in range of pressure, and have no fault to find with the results. In fact, after six or seven years' experience of their action on upwards of 2,000 lamps in the district, I find none to suit better, and we are replacing all our old class with them. The size of burner to use depends on the terms of your "lighting contract," and in ordering governors you must state the quantity of gas they must be adjusted to pass per hour. The manufacturer will then furnish the governors with the proper size of burner. If you follow my advice, you will not introduce reflectors in street lanterns. They may look very pretty and effective when new at an exhibition, and work very well on paper; but save me from such abominations as I have seen after being fixed two or three months in the streets. Nothing, in my idea, looks so well as a lantern with a nice light frame, glazed with pot opal on the top, and the bottom with clear glass (the lighting flap glazed with plate to prevent breakage by the torch; all fancy scrollwork cleared away from underneath the lantern, and a light basket frame substituted, just strong enough to support the lantern and no stronger, with the light not more than 10ft. 6in. from the pavement. This style of lighting is far before fancy reflectors: the white top, whilst throwing the greater part of the light on the pavement, allows sufficient light to pass through to give the lantern a cheerful appearance. —J. R. Warren.

[51735.]— **Boat.** — Cross your plan with ½in. squares; if you object to the pencilling over it, then you can divide it by fine threads; then rule a large sheet of paper to the particular scale for the enlargement, and carefully trace the contents of each small square into the corresponding larger one. If you desire to be desperately exact, you may use ¼in. or ⅛in. in the first instance. This must give a correct copy.—H. O'B.

[51748.] — **Water Rates — The "Dobbs" Case.**—The Grand Junction Act, 7 Geo. IV. c. 95, enacts that water rates be charged on "rent where the same can be ascertained," and where not, then on "the actual amount or 'annual value' upon which the assessment to the poor rate is computed." A later Act says simply, "annual value." Question 1: Is the old Act repealed? and if not, as Mr. Dobbs lives in his own house and pays no rent, what is his "annual value"? Question 2: If it is repealed what is "annual value" in the later Act? Decisions—Queen's Bench: Old Act is not repealed, and where no rent, "annual value" therein is the rateable assessment to the poor rate. There "annual value" *per se*, as referred to in the later Act, was not argued before the Court. Court of Appeal held also that the old Act was not wholly repealed, but decided it to mean rent if any, and where none, the equivalent of rent which is the annual or gross value from which the poor assessment or rateable value is computed, as otherwise the anomaly would arise that owners would pay water rates on a lesser basis than tenants. The Court further said that though "annual value," *per se*, had not been fully argued before them, they were of opinion that it would make no difference: they considered it the same thing as the rent in the old Act, or what is now called "gross value." House of Lords: That the decision of the Court of Appeal should be reversed, and that of the Queen's Bench restored, for reasons to be given at the next sitting. Mr. Dobbs, in a letter to the papers dated 18th August, 1882, said, "If the judgment of the Court of Queen's Bench is confirmed, my case is over on the narrow issue; but if the higher courts reverse the judgment, *then* we fight on the broader issue—viz., the meaning of 'annual value,' and every ratepayer will watch that, if it comes on, for though it will only bind the Grand Junction, it will forecast the result in other cases." The highest court deciding the first issue in Mr. Dobbs's favour, the question of annual value has not been fought out at all on this occasion: the effect is simply that owners living in their own houses in the Grand Junction district, are to pay on about one-fifth less value than tenants who are not owners—the very anomaly referred to by the Court of Appeal; but those vestries and ratepayers who have subscribed to Mr. Dobbs's fund under the delusion that his was a "general" case, have no right to blame him, as the above extract proves. It may be mentioned that two of the House of Lords judges, Bramwell and Blackburn, were parties to a decision in the well-known Sheffield case wherein it was decided that "annual value" meant the rent payable on an ordinary yearly tenancy, tenant paying tenants' rates, and landlord paying landlord's rates. There have been other decisions on this "annual value," in connection with the house duty and property tax, licensing acts, voting qualifications, and other questions, in all of which it bears one and the same meaning. See also the schedule in the Metropolis Valuation Act, 1869, where the forms to be filled up expressly define it as the rental or gross value, and the rateable value for poor-rate purposes as something to be calculated from it.—Q.

[51755.]—**Legal—Medical Electrician.**—If the testimonials have been addressed to B. only, they would no doubt be his property; but in that event I should make use of the local newspapers to explain same away, or go round to the persons giving the testimonials and get fresh ones addressed to A. only. If the testimonials are already addressed to

A. only, then they are A.'s property, and can be demanded, and on refusal obtained by action of detenue; but if addressed to A. and B. jointly, then explain them away in local newspapers, as in my first suggestion, and, if necessary, get an injunction and damages from one of the courts.—Lex.

[51756.]—**Cartridges for Martini-Henry.**—The powder used for this rifle is known as R.F.G.² (rifle fine grain) the (2) denoting a superior quality. It is manufactured at Waltham Abbey. The amount is 85grs. I can't understand how it is you found no wad in the Government cartridge, as there is a cardboard disc on the powder, then a wad of beeswax and then two more cardboard discs. The bullet is secured in the cartridge by the top of the case being choked into two cannilunes round the lower part of the bullet. The case is not solid drawn, but consists of two turns and an overlap of ·5in. of ·004 brass. The cartridge is a little off 3in. in length. The bullet consists of 12 parts of lead and 1 of tin, and weighs 480grs.—Artilleryman.

[51760.]—**Shoe Repairing.**—Good sewing must be learned by practice alone. Well wax eight cords of No. 12 white for ordinary men's, nine, even ten, if very stout soles, five or six for women's; then hang on a hook, pull all the stretch out, rub up and down once or twice, and it should resemble gut. Use awl so that the thread can only easily pass stitch behind, if possible, as sewing is not discerned. Strength does not depend on a thick thread; but cut channels as deep as possible, use wax every half-dozen stitches, pull all well together while moist with plenty of work, and, by all means, soak and well hammer your leather before sewing, if you wish it to wear.—A Mechanical Snobbie.

[51767.]—**Continuous Brakes.**—To "Historian."—From the description given by your correspondent, there can be no doubt that the train he saw at King's Cross, Metropolitan, was one belonging to the Metropolitan District Company, and, therefore (like all its rolling stock), fitted with the Westinghouse air-pressure brake. The brake has been in daily use on this railway since 14th February, 1873, upon which day the first trial trip was made on the line. From the notes I took at the time, I find the experimental train consisted of engine No. 18 and eight carriages, and it ran from the Mansion House to West Brompton. The carriages had previously had Clark's chain brake; but this was taken off, the brake blocks and some parts of the gear being, however, utilised. The Westinghouse air-pressure brake only requires *one* line of pipe throughout the train; but in this country two pipes and the check valves have always been employed, in order to prevent the possibility of failure. The statement of the official "that they have two sets of pipes, and that if one fails the other works," is perfectly correct. The two lines of pipe extending under the train connect to the brake cylinders and with each other, through a simple check-valve, so constructed that in the event of any damage to one pipe, it instantly and automatically cuts off communication between the two lines, leaving the unbroken pipe in perfect working order. The couplings are provided with valves, which are open when coupled, and closed when uncoupled. Therefore, if a train breaks loose, the driver has control of the brake on the front portion (and in cases where the vans are fitted with reservoirs the guards have control). This air-pressure brake was a great improvement upon previous systems, but it has the defect of being non-automatic. For further details of the brake I refer "Historian" to Vol. XV. p. 295, 1872.—Clement E. Stretton.

[51779.]—**Metallic Precipitates.**—I am afraid I have not explained clearly enough what I wanted. I would like to know the best way for precipitating separately:—Bronze as a metallic powder, copper as a metallic powder, and zinc as a metallic powder. —An Experimenter.

[51779.]—**Metallic Precipitate.**—What does "An Experimenter" really wish to do? Does he require to separate the constituents of the bronze by way of analysis, or to obtain each constituent in the form of metal for commercial purposes? The copper can be easily precipitated from an acid solution by means of scrap iron.—No Sig.

[51782.]—**To Violinists.**—"Amateur" should get a little work entitled "How to Hold a Violin and Bow," published by Pitman, which contains very good descriptions of the various bowings collected from standard works on the subject. Of course, however, "Amateur" is aware that a few lessons from a really good master would teach him more than any amount of reading. With regard to the bow, my opinion is that a good one can be bought for 20s. or 25s., and that the lower-priced bows must necessarily be inferior, as they are turned out in large quantities by the makers, who cannot take time to select the sticks. In this principally lies the difference between cheap and dear bows, as for the latter only the finest selected sticks are used. Some few makers, such as Tubbs, make beautiful bows, which are not dear at £3 or £4; but a guinea bow is quite good enough for all ordinary purposes. I do not think there is much art in rosining. Get good rosin, hold it in the left hand, and the bow in the usual position for playing, giving it three or four strokes on the rosin evenly from end to end, so as not to have more in one place than another.—War.

[51788.]—**Compound Engine.**—Seeing that "Engineer, Dewsbury," has not corrected an error in his answer to the above query, I take the liberty of doing so. The steam by gauge of 125lb. will, in reality, be 140lb. from pure vacuum line, or 15lb. below atmosphere, from which all calculations upon expansions must be reckoned, whether for condensing or non-condensing. Supposing there is no loss between the engine and the boiler, the steam will enter the high-pressure cylinder at 140lb. gross, and cut-off at one-third of the stroke. The final gross pressure will be 46·66lb. This steam has now to enter the low-pressure cylinder, whose volume is three times that of the high-pressure one, and whose cut-off is one-third of the stroke. Hence, to fill this space the steam must expand into one-third more of its volume, and thus become one-third of its pressure, 46·66 − 15·55 = 31·1lb. gross. This is the back pressure in the high-pressure cylinder, and not 41·66lb., as stated by "Engineer, Dewsbury." The back pressure in high-pressure cylinder will be 31·1 − 15 = 16·1lb. above atmosphere. The initial effective pressure will be 125 − 16·1 = 108·9lb. The final or terminable effective pressure will be 46·66 − 31·1lb. = 15·55lb. Next, the 31·1lb. of steam in the low-pressure cylinder is now cut-off at one-third of the stroke also, and expands through the other two-thirds of the stroke, and thus becomes two-thirds of its pressure, 31·1 − 20·73 = 10·36lb.; so if we allow 3lb. for back pressure in condenser, as stated, the initial effective pressure will be 31·1 − 3 = 28·1lb. The final or terminable effective pressure will be 10·36 − 3 = 7·36lb; so if we divide the initial effective pressure by the final effective pressure, we shall get the number of expansions in each cylinder. Now for the high-pressure one, 108·9 ÷ 15·55 = 7 expansions. The hyperbolic log. of 7 expansions, 1·946 plus 1 = 2·946, then 15·55 × 2·946 = 45·82lb. average pressure throughout the stroke. The horse-power will be 50·26 area of cylinder × 45·82 × 300 ÷ 33,000 = 20·9. Then 28·1 ÷ 7·36 = 3·8 expansions for low-pressure cylinder. The hyperbolic log. of 3·8 expansions is 1·335 plus 1 = 2·335. Then 7·36 × 2·335 = 17·2 average pressure throughout the stroke. The horse-power will be 153·93 area of cylinder × 17·2 × 300 ÷ 33,000 = 24.—Fiber, Dewsbury.

[51792.]—**Cancer.**—I had a great aunt who was a famous doctress 40 years ago. She recommended, beneficially, to my knowledge, best Turkey figs boiled in new milk, three or four to a pint, to be used in the diet, one or two figs every day, and also as a poultice on the sore or swelling. I would say try it: it is simple and harmless.—H. O'B.

[51792.]—**Cancer in the Mouth.**—I beg to inform "Nun. Dor." that he does not hold a correct opinion on cancer of the mouth. It is now a well-known fact—amongst surgeons—that this cancerous condition is produced by the irritation of the pipe. The reasons why we think so are—first, because it is nearly always seen on the lower lip only. Second, it is very rarely seen alone on the upper lip. Thirdly, it is very uncommon in women and amongst non-smokers. If "Nun. Dor." will consult any medical man who is fairly up in his work, he will get the same opinion as I have stated. —T. R. Allinson, L.R.C.P.

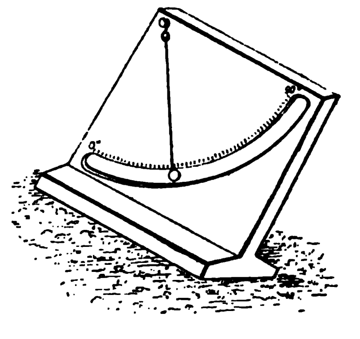
[51792.]—**Cancer in the Mouth.**—I regret that absence on the Continent prevented my seeing this query before. I have seen two cases of incipient cancer in the tongue within the last year, both of which have been cured under treatment of a non-surgical character. The doctor consulted was the famous Mr. Banks, of Liverpool, whose address would be found in a directory of that city. After some preliminary treatment, with a view to purifying and enriching the blood, both cases were sent by him to the baths of Aix-la-Chapelle, in Germany, on the borders of Belgium, not a great distance hence, nor an expensive journey to undertake.—D. de B.

[51804.]—**Reducing Thickness of Wire.**—I have tried rollers and failed, as it laps the steel wire. We use a small lathe, and it turns out some hundreds of gross per day. It requires a good mechanic to make the lathes. If "Eccentric" will advertise his address, I will advise him where he can get wires reduced in any shape he requires. —Perseverance.

[51806.]—**12in. Cylinder.**—I suppose "J. G." means that there is a space or "clearance," as it is generally called, of ⅛in. when the piston is at the end of the stroke, when he speaks of a "vacuum of ⅛in." Of course he will save steam, and lose no power at all, by filling in this most unnecessary space as he very properly proposes.—A. A. Myall.

[51806.]—**12in. Cylinder.**—In reply to "J. G." respecting the above, he had better either have two new cylinder covers ⅜in. thicker than those he has at present, or put a ¾ plate on each cover, taking care not to stop up any part of the ports giving free admission to the steam. As it remains at present, he is wasting his steam, which would amount to a considerable quantity in a day if the engine is worked many hours. ⅛in. is quite enough clearance. Shall be glad to give him any other information he requires.—Physis.

[51800.]—**Measuring Hills.**—The instrument required is a "clinometer," a simple form of which is sketched. It is constructed of wood 2¼in. square by ¼in. thick. The scale reads from 0° to 90°. The angle of inclination of the hill with the horizontal is the angle which is cut by the line of the plumb-bob.—Gassan.



[51808.]—**Legal—Bill of Sale.**—You would not be liable to any action for selling, unless you previously had notice of such bill of sale. The grantor is now liable to pay the grantee's balance debt.—Lex.

[51808.]—**Legal Replies.**—Take no notice of the loan society. They have no power to touch you, so long as you handed the cash of the goods sold to the customer, and the remainder of the goods to the society when demanded. Let them punish the customer. It might probably be different did you know at the time there was a bill of sale.—R. R. R.

[51809.]—**Cloudy Object-Glass.**—Soak them in spirit of turpentine for a few hours, then rub them gently with clean cotton wool soaked in the spirit, and finish off with clean wool and spirit. If the glasses are still stained, rub them with wool and strong nitric acid (this is highly corrosive), wash in clean water, and dry in a clean cloth. Take particular care to put the proper surfaces of the object-glass together, and if you want to re-cement them, put in the concave glass a small quantity of good, clear, clean Canada balsam, which you must obtain from a chemist. Warm the glasses gradually till you can scarcely bear them in the hand, and if the balsam contains any air bubbles, these must be pricked out with a fine needle, then lower the convex glass into the concave, taking care not to form or inclose any air bubbles. While the glasses are still warm press gently with a finger on the top of the convex glass in the middle, and move the glass a little bit to and fro; this will work out the greater part of the balsam, leaving a very thin film between. When the glasses are cold, this film will be hard enough to keep the glasses fixed closely together. Object-glasses larger than 3in. in diameter are not generally cemented.—J. C. L.

[51824.]—**Diaphorite** is thus described in Dana's "Manual of Mineralogy." Diaphorite = trimetric freieslebenite, and freieslebenite is described as a monoclinic antimonial silver and lead sulphide of a light steel grey colour, with specific gravity 6—6·4. It contains 22 to 24 per cent. of silver, and is found in Saxony, Transylvania, and Spain.—W. Farquhar.

[51825.]—**Testing Value of Watch.**—Your only way is to take it to a respectable jeweller or pawnbroker. No one through the pages of the "E. M." could give you information sufficient to enable you to safely estimate the value of your watch even approximately. The hall marks are stamped in when the cases are in the rough, at certain towns fixed by Act of Parliament. There are so many different marks relating to date of stamping, place of stamping, standard of metal, and manufacture of the article, that pages of the "E. M." would be required to describe and explain them. But if "Horo's" watch has English marked cases and is of 18 carat gold, it will have for one of the marks a crown, and if stamped in Birmingham another mark will be an anchor, and if "Horo," or any other reader of the "E. M." takes sufficient interest in the subject, he will find it treated exhaustively in the "Book of Hall Marks," price about 2s. 6d.—Hall Mark.

[51826.]—**Vacuum Brake on the L. and N. W. Railway.**—To "Vulcan."—The following trains on the London and North-West

QUERIES.

[51936.]—**Crystal v. Paraffin Oils.**—Would some reader oblige by giving a simple way of distinguishing between paraffin and crystal oil (Royal daylight)?—Chandler.

[51937.]—**Time Signals—Chemical Heaters.**—Will some obliging correspondent kindly favour me, in "ours," with a simple figure illustrating the most practical method of dropping a time ball by means of electricity? Please do not refer me to back numbers, as that is out of the question. Also will any one kindly inform me what carbon natron is? I learn from a German that it is used as fuel in a patent stove lately invented in Germany. Also that heaters are made, using acetate and hyposulphate of soda. Could anyone give me full particulars of these latter, and if they would be efficient in heating a room where the therm. seldom falls below the freezing point? Also the commercial value of the soda?—Ex. Nauticus.

[51938.]—**Musical.**—Would anyone kindly tell me why modern professors of music differ with the interval of a fifth—viz., C to G flat, some calling it a minor fifth and others positively declaring it to be a diminished fifth? And why Dr. Stainer, in his book on Harmony (when treating of the intervals), states in a table, p. 14, that a fourth is consonant, and also that a fourth (when not an inverted fifth) is dissonant?—Beethoven.

[51939.]—**Renovating Silk Mantle.**—A lady has a black corded silk mantle. The under side of sleeves and the front part is shiny, and has the appearance of being greasy. Can anyone inform me what will remove the shiny parts alluded to?—Preston.

[51940.]—**Waterwheel.**—Will any of our readers kindly state the method to find the nominal h.p. of a waterwheel 16ft. high, 4ft. abreast, with a 9in. ring working an 8in. plunger-pole 6ft. stroke, at the rate of ten strokes per minute, with a full supply of water?—Poor Labourer.

[51941.]—**Compound Locos, L.N.W.**—Is the gearing adopted for the high-pressure cylinders on the above engines Mr. Joy's patent? I see there is some difference between this and the low-pressure gear, though it may only be due to the position of the cylinders.—W. Thompson.

[51942.]—**Music-Halls.**—Can any of your readers enlighten me on the law of music-halls in reference to the following?—Can two persons (male) play a dramatic sketch in two acts? I have been told that they can safely, but that three persons cannot. Full information will oblige.—Dramaticus.

[51943.]—**Income-tax.**—A friendly society has surplus funds invested, and receives the interest at the bank half-yearly. A deduction is, however, always made for Income-tax. Ought the society to pay the tax? If not, can the amount be reobtained?—J. U. H.

[51944.]—**Coppered Wire.**—Can some of our readers tell me how common iron wire is made to look like copper? Also if it can be applied to hardened steel goods? What I want is some cheap and simple process without heat?—W. Henry.

[51945.]—**Boiler.**—Will any of ours say which of the two boilers is the strongest, both 30 by 7ft., and made of the same material: but the shell of one boiler has eleven plates, the other has only eight; both double-riveted in the longitudinal seams?—C. T.

[51946.]—**Rowlocks.**—I should feel obliged by information with respect to an arrangement of rowlocks which automatically "feathers" the oars, and another arrangement by which a person can pull with his face forward—as he sits when paddling. I believe both methods have been successfully tried.—O.

[51947.]—**Link-Motion.**—Will some one kindly give me a short description of Allan's "straight link" motion? Also a reversing gear without any slot-link at all.—Physis.

[51948.]—**Brakes.**—Perhaps some reader could inform me as to what brake is used on most of the G.W.R. locomotives running in the Bristol and South Wales district? Also a description, with small diagram, of Sergeant and Bolitho's automatic vacuum brake, used on the Midland Ry.—Physis.

[51949.]—**Zoophyte Trough.**—Having occasion to keep some pond water in a zoophyte trough, I found after a day or two that the trough had come to pieces—I suppose on account of the action of the water on the cement with which it was put together. Will any of our microscopical friends kindly give me instructions how to cement it together again?—Cymro.

[51950.]—**Loss of Smell.**—I should feel very thankful if any one can inform me in my case how to regain the power of smelling, having lost it for a very long time? I am 21 years of age, and a gasfitter, and the loss tends very much to my disadvantage, as I cannot smell the escapes.—E. H.

[51951.]—**Astronomical.**—It is stated in this week's "E. M." that the displacement of the planet Mars by the attraction of the earth amounts in two centuries to five minutes of arc, or about 200,000 miles. Wanted to know what the displacement of the earth, if any, by the attraction of the planet Mars amounts to during the same period?—J. M.

[51952.]—**Stage Micrometer.**—Can any one inform me how to make a stage micrometer, either by photography or otherwise? I have drawn very carefully on paper the divisions, &c., as I wish them to be in the micrometer, and have then arranged things, so as to get a photograph of exactly the requisite size; but, unfortunately, the deposit of which the image is made up is too coarse for the thing to be of any use,—too coarse even with a 1in. objective. I have tried various developers—iron, pyro, and gallic acid—and various strengths, but although the results are not all alike coarse, none are good enough for the purpose. I ought to have said that I have only used the collodion process. Albumen seems too troublesome, and vastly more liable to be spoilt by dust. I shall be very glad of any help, for I look upon it that one who can handle his microscope well, is a pretty good photographer, and not bad at mathematical optics, ought certainly to be able to make his own micrometer.—E. M. S.

[51953.]—**Electro-Motor.**—Would Mr. Lancaster kindly say if 22oz. of No. 16 cotton-covered wire was good proportions for field-magnets of small motor (Siemens' H armature), 3in. long by 2in. diam., and 6oz. 16 c.-covered for armature? Also what power it should give, it being mechanically well fitted together, and how many bichromate batteries it would require, say, zinc exposed surface 4in. by 3in.?—W. H. M.

[51954.]—**Cement for Fastening Indiarubber Slips in Steam Vessel Side-Lights.**—Could any readers inform me what is the name of the composition or cement used to fasten indiarubber strips into side-lights of steam vessels? It must be able to stand the action of sea water.—W.

[51955.]—**Electrical.**—Can any reader give me the approximate resistance of any of the Atlantic cables and their electrostatic capacity? How can I arrange an artificial submarine cable on the Varley system? How are the condenser plates arranged?—F. C.

[51956.]—**Incandescent Lighting.**—When a number of incandescence lamps are turned off, why should the remaining lamps increase in brightness if a separately excited dynamo is used? Theoretically for incandescent lighting a constant speed is required to maintain a constant E. M. F. Now this being done, say half the lamps are turned off, the resistance is doubled and the E. M. F. remaining the same the current is halved, which should leave the remaining lamps just their correct amount of current and no more, yet practically they always get more current when a number are turned off; the slight resistance of the armature is hardly sufficient to account for this variation. Will "Sigma" or others kindly explain?—F. C.

[51957.]—**Weak Magnets.**—To "Sigma" or Mr. Lancaster.—I have a Clarke's magnetic electrical machine which appears to be in good order, but which only gives a feeble current. The permanent magnets are of the horseshoe shape, and are five in number, screwed together; they weigh 14lb., but will only lift a piece of iron weighing 2½lb. Is not this small power in the magnets the reason for its not acting more satisfactorily?—and if so, please oblige by informing me how I can best remagnetise them? This query comes from the Antipodes, and I wish if possible to strengthen them here, and so save the time and expense of sending them to England.—Subscriber.

[51958.]—**Electro-Plating Query.**—Would some of the readers of "ours" who have practical experience in electro-plating by the cyanide silver process, kindly point out the cause and remedies for the following difficulty? Upon starting the battery everything goes on all right for a time; but the anode, instead of remaining clean, becomes discoloured and covered with a black deposit, and the plating ceases, or goes on very slowly. Does the cause of this rest with the solution or with the battery? An answer, with practical suggestions for keeping the anode bright and clean, will much oblige—An Amateur.

[51959.]—**Wasps' and Bees' Stings.**—Can anyone tell me the name and nature of the poison of the wasps' and bees' sting, and, also, how does a flea raise such a fearful blister?—F. G. A.

[51960.]—**Oxy-Hydrogen Microscope.**—To Mr. Lancaster.—I have lately purchased an oxy-hydrogen microscope, which has apparently been unused for some years, and is not quite perfect. To save the trouble of engraving diagrams, I may mention that the apparatus is exactly represented in "Pepper's Play Book of Science," p. 123, with the exception of Gurney's set, which I have not. The burner, which is made for using mixed gases, is composed of three parts; the lower part is screwed to the stand, the middle part is a tube of some 6in. in length, and has a tap at the bottom to connect it with the gasbag. This part of the tube appears to be packed with fine wires lengthways; the top part contains the jet and pin for lime cylinder, but at the lower part of it, and where it is screwed into the longer tube, there is a screen of fine wire gauze. Is this jet safe with ordinary care?—and how are the gases mixed in the bag, so as to have the proper quantities of each? The microscope consists of a large tube screwing into the camera, in the usual way, and it contains two lenses (condensers) 2½ diameter, and separated by a sliding part which can be regulated so as to move the lenses nearer or apart about 3in.; on the end of this larger tube, another tube slides, containing a stout spiral spring, and an aperture to hold the object to be magnified; attached to this is another tube, moved by a rack and pinion, and which I think should contain the object lens, but the lens is missing. There is another lens, however, attached to a loose brass plate, which slips in the end of the tube containing the aperture for the object. Will you kindly inform me what other lens is required, and the use of, the movable lens I have just mentioned? Can I use the condensers as a magic-lantern by adding the additional part to hold the slides and a tube for the object-glass? Any information will oblige an old subscriber to "ours."—Tasman.

[51961.]—**Cleaning Object-Glasses.**—Perhaps Mr. Lancaster, or "Prismatique" will kindly give me some advice in the matter of cleaning telescope object-glasses? I frequently find, after using my telescope at night out of doors, that the object-glass becomes speckled with something that is not exactly dust (notwithstand- the use of a dew cap) and which smears on being brushed when dry. To allow it to remain for long, not only means a loss of light, but surely must also do damage to the polish of the glass. Now mere brushing, as I said before, will not remove it, friction of some sort, with breathing, being necessary. And yet we are told by some ("F.R.A.S." in particular) to avoid wiping the glass. Of the two evils, which is the lesser? For my part, I cannot resist the temptation of removing it, and for that purpose I use a tuft of pure cotton-wool with gentle rubbing. Now is this likely to do harm if applied, say once a week? Also, is it advisable to wipe between the lenses, say once a year?—(What would "F.R.A.S." say to this, I wonder!) Some practical advice in these matters would, no doubt, be much appreciated by all who use astronomical telescopes in the open, and particularly so by—Achromatic.

[51962.]—**Water Company's Charge**
Mr. Wetherfield answer the following?—
beginning of the present year the New Riv
have served notices to the tenants of several
North of London, taking a few roads each
suppose to prevent combination, to pay an ext
water rate, and they quote the 70th cla
"Water Company's Act" as their authority
claim. I had paid the rate up to the 24th
because I had not paid another quarter in ad
cut the water off, and before I could have it
had to pay all expenses as well as a quarter
It appears to me that the quarter in advance
paid, as the 70th Clause reads:—"And the fi
shall be made at the time when the pipe
communicate with the pipes of the undertake
time when the agreement to take water from
takers is made." That would be at the tim
house was made habitable I should lik
whether the company were acting legally whe
the water off, or if I can sue the company for
O.

[51963.]—**Electrical.**—I desire to make a
(½-pint cup) carbon zinc battery, one cell, co
powerful enough to deflagrate platinum wi
used at night, the zinc or zincs might be slidi
batteries. Will some brother amateur say
or liquids are best, and how and on what met
should be fastened?—R. Hannen.

[51964.]—**Electric Battery.**—I have a
zinc battery. If I were to use chloride of
and muriatic acid instead of ch. of zinc, would
be prolonged? I use 1½oz. per cell of ch. of
much ch. of am. and muriatic acid should I
duce the same intensity, my object being on
longation of the battery power?—R. Hannen.

[51965.]—**Rash.**—To "The Kent Her
you advise in the following case?—A young la
of age has from childhood (it came on just aft
tion) been subject to a rash which makes its
at the fall of each year, and after a while
open cracks just at the bend of the arm. Thi

Thomas Blackburn.

[51975.]—**Resistance.**—Will any rea
Kirchhoff's bridge, and how it is used to me
ances, or say where a description may be fo
S. H.

[51976.]—**Piano Wrest Plank.**—An
piano has a crack running through all the w

It is in a village far from any piano repairer. One tuner suggests an iron plate, and another the insertion of a new piece of wood. Which is preferable? Could an intelligent village joiner be trusted with the work? Hints how to proceed and what to avoid will be thankfully received by—M. C. S.

[51977.]—**Ejector.**—I have taken in hand the repair of a steam launch, and amongst the list of things I got from owner to be overhauled is a small ejector, used for ejecting bilge water, which has never given satisfaction in its water-ejecting powers. I had a trial with it myself, and find it lifts water after having a little patience with it; but it will not continue working (I mean ejecting water) more than half a minute or so. It lets slip the water, and then we have to commence anew with it, which is a great nuisance, as steam launch is used greatly by a lady and gentleman, with family, having always steam from ejector flying amongst them. It is not quite exactly the thing for a steam launch that is mostly used for pleasure. They are in general got up with everything about them neat, clean, and all in good working order, which my endeavours will be to put out in the same style as above mentioned. I put a new cone into inside of ejector, having found it was bored or turned all to one side, also cut suction pipe and placed ejector 10in. above level of water; but with just the same result as before. Will some practical reader of "ours"—for example, "Glatton," S. Austel, or "London River"—kindly give their opinion so as to assist me out of my difficulty?—Hombre.

[51978.]—**Hyposulphate of Soda.**—Would any of your readers kindly say if the above can be cheaply made from ordinary washing soda or any other compound of soda? I am going to the colonies in a week or two, and am afraid I shall have a trouble to get the hypo.—Hypo.

[51979.]—**G.W.R.**—Can any reader oblige me with the size of driving-wheels, &c., (1) of the Nod. B. G. singles; (2) of engine No. 152, 4 c., N. G., which appears larger than other N.G. engines?—T. M. R.

[51980.]—**Cattle Spice.**—Would one of "ours" insert a recipe for making a cheap condiment or cattle spice suitable for flavouring some chop cut from hay of moderate quality? I should like to know the quantity of each ingredient used.—Condiment.

[51981.]—**Electric Testing.**—In connecting the terminals of a galvanometer to a 4½in. bell as fixed in going order, a slight (5 degrees) deflection is seen. If I remove either one of the bell's wires and again insert galvanometer as before, the needle is deflected as far as possible. I can find no leaks, connections of wires or anything wrong, the pushes are all good. This wasting current is insufficient to ring a very small bell, though the hammer perceptibly moves when such bell is inserted in place of the galvanometer. How can I find the fault?—where is the probable defect? There are five bells, two semaphores, a needle instrument, a relay, and an annunciator, all on the battery—a four-cell chloride of zinc. Help is solicited.—R. Hannen.

[51982.]—**Electro-Magnetic Machine.**—I have a small electro-magnet of soft iron, horse-shoe form, core ¾in., poles 1in. apart, capable of lifting 25lb., which I want to take part in an electro-magnetic machine. Will Mr. Lancaster or any correspondent tell me size of armature, weight and gauge of wire for each bobbin, to get good result, even to producing a small electric light? A. C.

[51983.]—**To Mr. W. J. Grey.**—Will Mr. Grey be kind enough to recommend books for machine construction and practical geometry, Honours stage?—I have passed in Advance. Does he know of any published information concerning the Whitworth scholarships, other than the prospectus of the Science and Art Department? Answer to the above will greatly oblige.—A. P. G.

[51984.]—**Dissolving Guttapercha.**—Can anyone inform me the exact strength of spirits required to dissolve guttapercha or indiarubber?—H. F.

[51985.]—**German-Silver Leads.**—Can any of our scientific readers help me out of this difficulty? I want to know what diameter and length of German silver wire is required to equal 1 ohm resistance, and to carry 100 ampères of current, without heating. Any information on the subject will oblige.—H. F.

[51986.]—**Electric Currents in Dynamos.**—Will "Sigma" kindly explain why the polarity of the field-magnets in the alternate dynamo is not reversed by the current from the armature? I hoped to be in possession of his second edition of "Electricity" before this. How soon may we expect it?—Field-Magnet.

[51987.]—**Hunnings Telephone.**—Would some one be good enough to describe the receivers and transmitters of the above telephone system? If formerly described, my back numbers do not go back sufficiently far.—Micro.

[51988.]—**Tapering Corks.**—I shall be glad if anyone can give me particulars of a machine for this purpose, and if attachable to a lathe so much the better.—C. W. F.

[51989.]—**Burnisher.**—I have been making a burnisher, the burnishing surface being of soft steel, while the roller above is of brass. I find, however, that the steel plate invariably scratches the card which is being burnished. Recently I got the plate hardened and polished, but with no better result. Would substituting a steel roller in place of the brass be an improvement?—If not, what is the cause and what the remedy?—J. A. Hislop.

[51990.]—**Carriage Lift.**—I am desirous of raising and lowering carriages from one yard to another, the height of the top yard from the lower one being 13ft. Can any reader advise me how to do this effectively and as cheap as possible?—Tynedale.

[51991.]—**Star Magnitudes.**—Will any correspondent kindly oblige me with the following particulars? (1) The exact magnitudes of these stars (all of which are classed as 3rd. mag. in Proctor's small Atlas):—α Andromedæ, α Coronæ Borealis, α Ophiuchi, α Capricorni, γ and λ Ursæ Majoris. (2) The name of any good French periodical partially or wholly astronomical, with its published price. (3) The position and mag. of the star 1830 Groombridge.—Stella.

[51992.]—**Metallo-Chromy.**—Can any of ours give me information on the above? I tried soaking white blotting paper in sugar of lead and put a strip of tinfoil on each edge to battery, but get no results. What battery power, and would a coil help?—G. Reed.

[51993.]—**Engine Query.**—Would any one of ours help me out of a difficulty? We have a condensing engine working at 60lb. pressure and 140 revolutions per minute. There is a loud thumping noise at the crank bearings when the piston is at each end of the stroke; if the brasses are tightened so as to minimise the thumping, they heat. What is the cause of the thumping?—is it defective cushioning?—and how may it be remedied?—C. Guillaume.

[51994.]—**The Heliostat.**—I am reading with great interest your account in the "E. M.," of the "theory and construction of the Heliostat." For the last twelve months I have been working with a 9in. reflector; but, like a good many other workers of that form of instrument, I am increasing my size of aperture. Suppose with my new instrument I did away with the stand, and put the mirror and tube in a fixed and horizontal position, could I use a heliostat?—and if so, what form, to throw the rays of a planet or star on to the mirror and keep it there? I have read that it is used in America; but beyond that I have never been able to meet anyone who could enlighten me on the subject.—M. T.

[51995.]—**Extracting Dust and Lime from Wool.**—Can any reader give me a description of a hand power machine suitable for use by a fellmonger to extract the dust and lime from wool?—also to beat it out thoroughly? The wool requires to be treated directly after leaving the stove, but the staple must not be broken. Would a winnowing machine be of any service?—Country Fellmonger.

[51996.]—**Drying Crystals.**—Wanted to dry, or calcine, 30 to 40cwt. of crystals per week. Our present system consists of a brick kiln, heated by coal, the flues being returned twice above, and below a central compartment, containing eight iron circular open topped pans, revolving slowly; these hold about 35lb. each, and will do two or three charges per day, with a heat of 300 Fahr. They require a man's almost constant attention, stirring them three or four times an hour to prevent the small and the bottom of the pan from browning. Can any reader suggest (1) a better system of heating by steam, or otherwise? (2) any different kind of pans. (3) An automatic arrangement for thoroughly stirring the whole. Any information, with sketch if possible, and whether tried or not, will oblige.—Amylin.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* Editor *of the* English Mechanic, 31, *Tavistock-street, Covent Garden, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

***** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.**

The following are the initials, &c., of letters to hand up to Wednesday evening, Oct. 10, and unacknowledged elsewhere:—

H. S. Walter.—H. B. Fulton.—T. Bastow.—T. Richards and Co.—Kell, Meats and Co.—H. Milner.—J. G. Nicholle.—L. A. Eddie.—F. H. Cowle.—E. P. Alexander.—Volta-Metre.—Rev. Jas. Pearson.—Jas. MacNab.—S. Mills.—Wm. Archbutt.—A. S.—A. Best.—W. Hardie.—F. G.—S. Bottone.—J. C. H.—H. Faulds.—Oudeis.—Richmond.—T B.—T. T.—Bilston. Alpha.—A Would-Be Fat-Extractor.—Codadad.—Amateur Millwright.—J. D.—Simplex.—Eta Orionis.—Spark.—Brass.

A. S. (The query has been answered many times: once or twice in each volume, we should think. Try pp. 506, 529, 552, 577, 599, Vol. XXXV. 2. There is no book answering the description.)—Horace Claydon. (You will find one process given last week, p. 101, and many others by searching the indices.)—B. G. W. (See the index to the last volume, and also pp. 508, 552, 574, 597, Vol. XXXVI.)—Petro. (By "lenitiv
tuary" is usually understood confection of senn
that is a very doubtful compound as
recipe is senna 8oz., corianders 4oz.
separate with a sieve 10oz. of mixed
of figs and 3oz. of bruised fresh liquo
of water until reduced to about a half
and reduce still more by gentle heat
sugar and ½lb. each of prepar
prunes. Remove from heat,
add the powder, gradually
thoroughly mixed.)—O. W
clear what it is you mean
instrument, see pp. 120, 1
"Manual of Instruction i
6d. There is a full descripti

Liverpool. (We do not recognise the book from the title you give; but probably some of the music dealers in your city can answer your questions.)—A Country Carpenter. (Better take the advice of your "doctor," who will know what kind of truss is best, and where to get it." 2. Size in the usual way, and give it a coat or two of best copal.)—Africa. (1 No. It is not suitable, as it gives a powerful current for a short time only. Get a Daniell, and look up the indices. See pp. 237, 261, 285, 308, 381, Vol. XXXIV. 2. Watt's "Electro-Metallurgy," Crosby Lockwood and Co., Stationers' Hall-court, E.C., price 2s 6d.)—Ignoramus. (For electric bells, see list of Back Numbers in this column last week.)—Inquirer, J. H. (If they have been plated originally, replating is the only cure. You can try polishing with the brush and rouge, and if that does not improve them, the plating is worn off. You will find a number of recipes in back volumes for washing and dipping such things.)—Inquirer, W. H. L. (A small dynamo to do only what you want has not yet been made, we believe, because to do so much it must be large enough to do more. See the indices of Vols. XXXV. and XXXVI.; also the articles now being issued.)—Gas Engineer. (Bunsen battery best for the purpose, but cells must be placed where the fumes are not a nuisance. Your question is too general to answer fully, as the size of battery depends on the lamp you intend to use. You will find all needful information in back numbers.)—J. McE. (1. We do not remember to have seen proportions stated. Most people find out what is suitable by "trying." 2. Captain Galton's paper was read at a meeting of the Institution of Mechanical Engineers on April 24, 1879, and is presumably to be found in the "Transactions" of that society. You will, however, find "all about it" in back volumes, and some special notes on pp. 187, 212, 280, Vol. XXIX. 3. We believe the address is the Electric Power Storage Co., 4, Great Winchester-street, E.C. 4. The Westinghouse brake has been illustrated and described in many numbers, as parts were improved or altered. Look through the indices, commencing with pp. 578, 627, Vol. XXVI. You can obtain an illustrated description from the company.)—Generator. (You must refer to back numbers for information of that kind, and study the series of articles now being issued.)—Enquirer. (Glue one part, glycerine four parts, whiting to colour. See list of Back Numbers given in this column last week.)—Painter. (What do you mean by "common varnish"? see the indices.)—L. S. (No one can tell you what is the matter from so bare a statement; and surely you would not be so foolish as to try any remedy that might be suggested. There is nothing very remarkable in the symptoms; but if they continue, consult an eye surgeon.)—One in a Fix. (See p. 330, Vol. XXI. You do not require a bellows at all. Simply a piece of wood with a bit of wire and a lead weight stuck in one end, the other being hinged. As the wind is forced past this valve will "tremble.")—B. H. (Mr. Lancaster will probably give them as soon as he has time. 2. The generally received opinion is that the current passes from the zinc through the liquid to the carbon or copper, and thence by the connecting wire back to the zinc.)—N. O. B. (Your question is not very clear, but the stickiness depends on the paint; add gold size or copal varnish to your colours.)—Ego Nemo. (It depends on so many things that it is impossible to answer the question definitely. A large magnet would give more power than two half the size. Look up the question in back numbers.)—Novice. (We cannot form an idea of what you want. Procure a list from Mr. Van Voorst, Paternoster-row, and see if it contains anything likely to suit.)—A. M. S. (The telectroscope was illustrated and described on p. 584, No. 829. Nothing very practical has come of it yet.)—C. B. (It is solution of nitrate of mercury. The "polish" is not permanent, but the application of the solution has the effect of rotting the metal.)—Iota. (You should read up the subject in back numbers. The report referred to is no doubt to be had of the Queen's Printers, East Harding-street, E.C.)—A Lover of "Ours." (Why did you not say so before? They are gaspipes, and have nothing to do with the brakes. 2. We really have no space to spare for the question about corns and rainy weather. 3. What is the explanation needed? The arrangement is common; one high-pressure and two low-pressure cylinders.)—Anxious One. (Get examined by a medical man.)—An Amateur E. P. (You should look through recent volumes. Make it of slate; if of lead, it must be burned; that is, the joint made with lead. 2. Polishing buffs in the lathe.)—Buchan. (Apply to the booksellers, if you mean books. There is the *Chess Player's Chronicle* and the *Chess Monthly*.)—H. (The best treatment is that which will be recommended by medical men after examination. After a time local changes in nervous parts take place, and then a cure is almost impossible.)—W. B. (Pale gold lacquer: 1 gallon of spirit, 10oz. of seedlac, and ½oz. red sanders. The substance to be coated must be made as hot as can be held.)—Student. (Surely you ought to be able to answer for one of the places! There is no special library of the kind in London, but most of the good libraries have scientific books.)—A. B. C. (Subject has been frequently mentioned in these pages, but nothing satisfactory elicited. On the contrary, the general opinion seems to be that gas or fuel are the only trustworthy agents.)—R. F. Eaton. (You mean putty powder. It is calcined peroxide of tin.)—Old Subscriber. (It is crushed by stamping mills, and sifted through sieves of different mesh.)—R. J. (Do you mean they are simply dull, or that the tin is worn off. If the latter, it would scarcely be worth while re-tinning.)
(Clothes are necessary, if supplied accord-
station of life and the parents' means,
will have to pay.)—Jas. Wright.

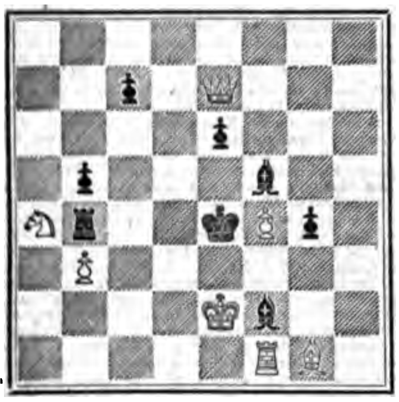
PROBLEM DCCCLVI. - Else.

Black.



White. [7+8

White to play and mate in two moves.

Solution to 854.

White.		*Black.*
1. P Q B 4		1. K-Q Kt 5 (*a*)
2. Kt takes P (ch)		2. Kt takes Kt mate
	(*a*)	1. Q takes Q P (*b*)
2. Q takes P (ch)		2. R or Q takes Q, or Q covers, mate
	(*b*)	1. Anything else
2. Q or Kt × P		2. Mates

NOTICES TO CORRESPONDENTS.

Correct Solutions to 852 by F. P. P. (2nd solution); to 854 by Mortimer, C. Planck (duals in strong force: White is so hemmed in that Black has to do all he can to avoid mating in *one* move), R. A. Bennett, S. Seymour Follwell (not very difficult).

English Mechanic Tourney game between Mr. Studd (*White*) and Mr. Vincent (*Black*):—

(Evan's Gambit declined.)

1. P-K 4, P K 4 2. Kt-K B 3, Kt-Q B 3/3. B-B 4, B-B 4/4. P-Q Kt 4, B-Kt 3 5. P Q B 4, P-Q R 3/6. P-B 3, Kt-B 3/7. P Q 3, P-Q 3/8. P-R 3 (*a*), P-K R 3/9. Q Kt Q 2, Kt-K 2 10. Q-Kt 3 (*b*), Castles 11. P-K Kt 4 (*c*), P Q B 3 12. Q-B 2, P Q 4 13. P takes P, P takes P 14. B-Kt 3, Kt-Kt 3 (*d*) 15. P-B 4 (*e*), P-K 5 16. P takes K P, P takes K P 17. P-B 5 B-B 2 18. P-K Kt 5 (*f*), P takes Kt 19. Q takes Kt, Q-K 2 (ch) 20. K-Q sq, Q-K 7 (ch) 21. K-B 2, Q-K 4 22. B-Kt 2, B B 4 (ch) (*g*) 23. K-B sq, Q B 5/24. Q takes B, Q takes Q/25. P takes Kt, B B 5 26. Resigns.

Notes.

(*a*) Too defensive. We prefer Q-Kt 3, followed by Castling.

(*b*) B R 2 would be less cramping, or Q-B 2; as it is, the Q has to retreat two moves subsequently.

(*c*) Very compromising.

(*d*) Black has already the better game.

(*e*) Having ventured so far, White might have risked P K Kt 5.

(*f*) White should have seized the opportunity and Castled: even Kt R 2 or B B 4 would have been safer.

(*g*) This seals his opponent's doom.

Longevity.—A Venerable Dame.—At Auberive-en-Royans, a village in the Dauphiné, situated between Valence and Grenoble, may be seen an old woman living in a hut in a narrow street who has reached the extraordinary age of 123. She has no infirmity except slight deafness, being in full possession of her mental faculties. Her age, as given above, is authentic, and according to her marriage certificate she completed, in January last, her 100th year since marriage. The old lady was a "cantinière" under the First Empire, and had two sons killed at the battles of Friedland and in Spain. She is supported entirely on the alms given her by visitors, who go from great distances to see her as an object of curiosity, and her neighbours help her to do her household work. She lives almost exclusively on soup made with bread, to which is added a little wine and sometimes a little brandy. Dr. Bonne, who practises in the neighbourhood, states that she is never ill. Her skin is like parchment, but she is comparatively upright, and is of scrupulously clean habits.—*Lancet*.

SPECIAL ANNOUNCEMENT.—Every Purchaser will be entitled to receive a copy of our GRAND WINTER CATALOGUE, illustrated with upwards of 200 engravings of Specialities and Novelties for personal and domestic use.

A GRAND OPPORTUNITY.
DO NOT MISS IT!
TEN THOUSAND
"COMBINATION" KNIVES

TO BE SOLD AT AN EXTRAORDINARY REDUCTION.

For COMPACTNESS ELEGANCE, USEFULNESS, and QUALITY, no knife has been manufactured to surpass the article we offer. They are of superior Sheffield manufacture, and comprise the following useful articles: Two Blades of the finest steel, Corkscrew, Rimer, Stone Extractor, Cork-squeezer, Nutcracker, and Screw-driver. The handles can be had in either white or stag, beautifully mounted with a Nickel-Silver Plate, on which we will engrave any Name or Initials FREE OF CHARGE. As we have made this offer in order to clear out our enormous stock, we trust that the thousands of readers of the English Mechanic will liberally respond by sending for a sample to show their friends, and we guarantee to satisfy and ASTONISH every purchaser.

We have the knives in three different qualities:—

A contains all the implements mentioned above. Price 2s. 6d., or 33 stamps.

B contains, in addition to the above mentioned Tools, a pair of Tweezers and a Toothpick, and all the implements are of a superior quality. Price 3s. 6d., or 45 stamps.

C contains a great variety of implements, including Saw, Gimlet, and all the Tools mentioned above. It is of the *very best* quality, and the handle can be had in either ivory or best buckshorn, with handsome shield. Price 6s. 6d., or 81 stamps.

POCKET NAIL SCISSORS.

The patent having just expired for manufacturing the above pattern folding Nail Scissors, we are enabled to offer them at half the price at which they have hitherto been sold. Each pair opens to the full size of the ordinary nail scissors, and folds up to two inches, and is enclosed in a beautiful leather case, specially made for the purpose, which can be carried in the waistcoat pocket. No purchaser can fail to be delighted with this pretty and useful novelty, and we are so confident in their giving satisfaction, that we will willingly return the money in full to any dissatisfied customer.

They are made in two qualities:—

Plain Steel, complete, with case, price 3s. 6d., or 45 stamps, post free.

Superior Steel, beautifully nickel-plated, with fire-gilt bows (warranted not to wear off), enclosed in handsome leather case, price 5s., or 63 stamps, post free.

A SET OF TOOLS FOR 5s.,

CARRIAGE PAID, 5s. 6d.

By purchasing one of our sets of Braces and Bits the purchaser will be in possession of a complete set of Tools.

The Bits, twelve in number, consist of the following articles:—

Turnscrew, Rimer, Augers, Centre Bits, and a variety of other useful Tools indispensable in every household.

To Carpenters and Amateurs we recommend with every confidence the above set of well made and highly finished Tools.

We will forward the above Carriage Paid, on receipt of P.O.O. for 5s. 6d. (or 69 stamps)—the usual retail price is half-a-guinea.

The above can also be had with 18 bits, carriage paid, on receipt of P.O.O. for 6s. 6d. (or 81 stamps).

THE ARCHIMEDEAN DRILL AND SIX BITS.

PRICE HALF-A-CROWN, CARRIAGE PAID.

Indispensable to every Mechanic and Amateur Carpenter. We warrant the quality and workmanship to be of the best, and anticipate a great demand for this ingenious Amateur's Companion.

Send P.O.O for 2s. 6d. (or 33 stamps), and you will receive a complete set, carriage paid, the next day. Large size, and better quality ditto, price 3s. 6d. (or 45 stamps), carriage paid.

ALL ORDERS EXECUTED SAME DAY AS RECEIVED
P.O.O.'s PAYABLE AT THE G.P.O., LONDON, TO

Drallim & Oliver,
18, IRONMONGER LANE, CHEAPSIDE,
LONDON, E.C.

(PLEASE MENTION THIS PAPER.)

Every Workman connected with the Building Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 31, Tavistock-street, Covent-garden, London, W.C.

"THE BUILDING NEWS" is the Principal Journal, representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is One Shilling for Twenty-four Words, and Sixpence for every Eight Words after.

CHARGES FOR ADVERTISING.

	s.	d.
Thirty Words	2	6
Every additional eight words	0	6

Front Page Advertisements Five Shillings for the first 40 words, afterwards 9d. per line. Paragraph Advertisements One Shilling per line. No front page or paragraph advertisement inserted for less than Five Shillings. Reduced terms for series of more than 6 insertions may be ascertained on application to the Publisher.

⁂ It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid, no reduction is made on repeated insertions, and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.

The address is included as part of the advertisement, and charged for.

Advertisements *must* reach the office by 1 p.m. on Wednesday to insure insertion in the following Friday's number.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve Months, Post-free to any part of the United Kingdom. For the United States, 13s., or 3 dols. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. James W. Queen and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post-free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. XXIV., XXVI., XXVII., XXVIII., XXX., XXXI., XXXII., XXXIII., XXXIV., XXXV., and XXXVI., bound in cloth. 7s. each. Post free, 7s. 9d.
Vol. XXXVII. now ready, price 7s.; post free, 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in March and September, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post-free from the office (except index numbers, which are 3d. each, or post-free, 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI. and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a Pink Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

Holloway's Pills purify the blood, correct the bile, excite a healthy appetite, produce sound sleep, and impart increased energy to both mind and body. The admirable properties of these far-famed Pills are too highly appreciated to require any encomium here, as they are resorted to by rich and poor of every nation.

Exhibition, must have rather astonished a good many people when they reflected that such an invention lay dormant for 13 years. In this letter, Reis says that "*any* sound will be reproduced, if strong enough to set the membrane in motion" (the word any being underlined); and as it is known that instruments made after the model of Reis's will transmit speech, it would seem clear that anyone can make and use them without infringing the "monopoly" patent. Prof. Thompson says that Philipp Reis was the undisputed inventor of an instrument which he called the telephone, which can now be used to transmit speech, which was then used to transmit speech, and which was invented on purpose to transmit speech. It seems to us that he has proved his case completely. In order to leave no doubt, Prof. Thompson goes further, and in an appendix he shows that there is not a single telephone in the Exchanges of England in which the fundamental principles of Reis's telephone are not the essential and indispensable features. It will naturally be asked why Reis did not prosecute his invention to commercial success. The answer will be found in the fact that he was only a "poor teacher," and that he was overtaken by severe illness, which ended his career on January 14, 1874. That, however, was 15 years after the telephone had been first described to the Physical Society of Frankfort; and two years afterwards, Bell's instrument (the magneto-telephone) was described in all the scientific papers, and attracted the attention of speculators. The most important exhibition of the telephone was at Giessen, in September, 1864, at the meeting of the German Naturalists' Association; but although experiments were conducted before the most distinguished scientists of Germany and several foreigners, no one save Reis appears to have apprehended the great value of the invention. A few of the public journals noticed the telephone in eulogistic terms; it found its way into the textbooks, and it was lectured upon in all parts of Germany. Besides the extracts from papers and textbooks, Prof. Thompson gives the testimony of nine contemporary witnesses, who were either personally acquainted with Reis or had experimented with his instruments years before the introduction of Bell's telephone. In the Appendices he points out the similarity in principle, the differences in construction between Reis's instruments and the best known telephones, both transmitters and receivers, and in doing so Prof. Thompson has written a chapter which will be very useful to all who wish to study the telephone. A monument was erected in 1878 to the memory of Philipp Reis in Frankfort cemetery by the Physical Society of that city, and when his jubilee is celebrated on the 7th of next January, it may be expected that his claim to be the inventor of the telephone will be recognised on all sides.

Study and Stimulants. Edited by A. Arthur Reade. Manchester: A. Heywood; London: Simpkin, Marshall, and Co.

This is a revised edition, with additions, of a work which may have some influence on the future consumption of alcoholic beverages and tobacco, as there are many people unable to argue out a question for themselves who will follow what they understand to be the practice of some one whom they look up to as a "leader." The opinions recorded in this book are interesting as the personal experiences or idiosyncrasies of men who are more or less well known to the world: their scientific value is very small. The reply of Prof. Tyndall sums up the whole question as succinctly and pertinently as need be. He writes, "With regard to the use of alcohol and tobacco, I *do not think any general rule* can be laid down. Some powerful thinkers are very considerable smokers, while other powerful thinkers would have been damaged, if not ruined, by the practice. A similar remark applies in the case of alcohol. In my opinion, the man is happiest who is so organised as to be able to dispense with the use of both." Others write in a different style to that, and give some details of their personal habits. Thus Mark Twain says he is forty-six and has been an immoderate smoker for thirty-eight years. During the first seven years of his life he had no health, and lived on allopathic medicines; since then he has hardly known what sickness is. The inference is obvious, especially when we find that Mark Twain now smokes three hundred cigars a month, and began with an allowance of one hundred per month. "Professor" Edison, as he is here called, almost invariably chews tobacco as a stimulant when engaged on experimental work, which he does at night. Mr. Reade may gather a few hundred more opinions; but we think he will get nothing more to the purpose than Prof. Tyndall's "opinion," which, it will be seen, did not contain an account of his personal habits.

Saw Mills: their Arrangement and Management. By M. Powis Bale, M.Inst.M.E. London: Crosby Lockwood and Co.

This is a companion volume to the author's "Wood-working Machinery," and will doubtless be found useful by those who desire to invest their capital in the conversion of timber. The book is confined almost exclusively to saw mills, though the author has inserted his viewsas to the best manner of setting the engine and boiler, and has reproduced his rules for engine-drivers and boiler attendants, which, useful in some respects, are rather amusing (to the skilled attendant) in others. The author gives a number of tables and rules which will be found useful; but in most cases the saw-mill owner will have to use his own judgment, and make experiments with his plant. As the book is furnished with an index, it will be a welcome addition to the shelves of the office library.

We have also received the second edition of *Saturated Steam, the Motive Power in Volcanoes and Earthquakes*, by R. A. Peacock, C.E., F.G.S. (E. and F. N. Spon), which contains an important supplement, and is especially interesting now that the disturbances of the earth's crust at Ischia and Sunda Straits have drawn public attention to the question. The work consists of a large number of extracts, by which the author seeks to support his contention that "saturated steam" is the cause of earthquakes and volcanoes.——*The British Navy*, by Sir Thomas Brassey (Longmans), is the fifth volume of a work we have already noticed at considerable length. The present part deals with "British Seamen," especially as found in the merchant service, and is a careful compilation of the opinions of experts and extracts from reports. It forms the concluding volume of a work which will be especially valuable for reference.——*The Chemistry of the Secondary Batteries of Planté and Faure*, by J. H. Gladstone, F.R.S., and A. Tribe, F.I.C. (Macmillan), is a reprint in the "Nature Series" of the classical researches of the authors. It is, we need scarcely say, the most valuable contribution to the theory of the secondary battery yet made.——*Electricity and its Uses*, by J. Munro (the Religious Tract Society), is a popular description of the most noticeable phenomena of electricity, as illustrated by the numerous appliances invented in recent years. For instance, Mr. Munro illustrates and describes the Wimshurst influence machine, which he says is the most remarkable of all plate machines, Edison's and other telephones, Brush and other dynamos, the induction balance, the electric furnace, and Trouvé's appliances for driving his electrical boat. The book gives a very good idea of the present position of practical electricity.——*Practical Electrical Units Popularly Explained*, by Jas. Swinburne (E. and F. N. Spon), is a very useful little handbook which will explain to tyros how calculations are made in connection with electric lighting, &c.——*Building Estates*, by Fowler Maitland (Crosby Lockwood and Co.), is a useful addition to Weale's series, as it gives trustworthy information on the development, sale, purchase, and general management of building land, including the formation of streets and sewers. The work is illustrated with diagrams, which help to render the text comprehensible.——*Farm Roads, Fences, and Gates*, by John Scott (Crosby Lockwood and Co.), is also an addition to Weale's Series, and a complement to the same author's useful works on agricultural subjects. It is very freely illustrated.——*Arithmetical Chemistry*, by C. J. Woodward, B.Sc. (Simpkin, Marshall, and Co.), is the second part of a useful work for both teachers and students of chemistry. The examples are taken chiefly from original memoirs, and from examination papers, and will be found especially useful by private students who lack the advantages supplied in classes.

THE DYNAMO: HOW MADE AND HOW USED.—VI.*

By Selimo R. Bottone.

Soren Hjorth's Machine.

§ 13. The next great step in the development of the dynamo, was the application of the current generated by the armature to the heightening of the magnetism of the magnets which set up that current in the armature. We have seen (§ 7) that a current sent round a mass of soft iron, converts that iron into a magnet, and we find that the intensity of magnetisation, is, up to the point of saturation, proportionate to the quantity of electricity flowing round the iron. We also know that magnets produced by such means (id est, the passage of currents *around* soft iron cores) are much more powerful than permanent steel magnets of equal size and weight. Hence, apart from the question of less expense and greater constancy (for steel magnets gradually lose their power by the continuous motion of the armatures before their poles) there is actually a great gain in efficiency, in employing *electro-magnets*, instead of *permanent magnets*, wherewith to induce the current. In Hjorth's machine, (which was perfected so far back as Oct. 1854) two compound cast-iron magnets A A, Fig. 11, which may or may not be surrounded by a coil of wire, are bolted to the frame of the machine. These magnets are shaped like the letter **C**; and in the gap between the poles rotates a wheel B B, on the circumference of which are fastened several armatures, consisting of soft iron

wound with insulated copper wire.

which are brought out to a pecul

commutator, which rectifies the

produced. The wheel (an

armatures) is caused to rot

rigger C, and driving axle

able armatures, and also

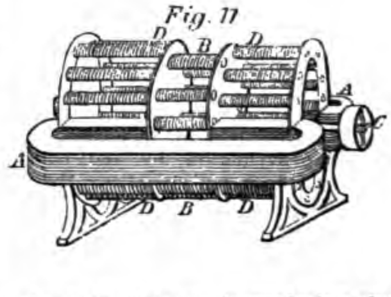
tures before the poles of the

being rendered uni-d

Fig. 11



---

* Ap

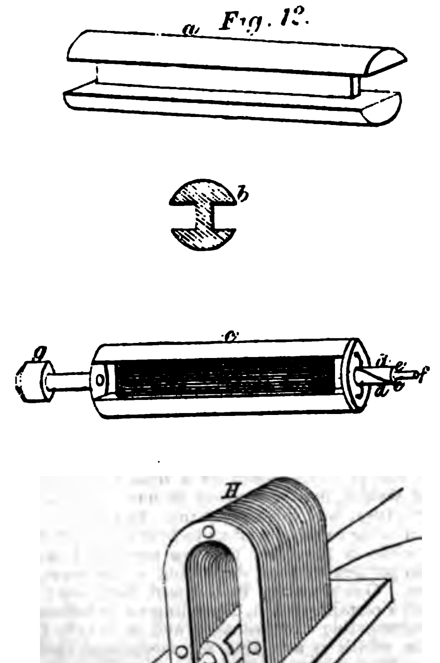
commutator, are led on through wires to the coils which surround the soft iron cores D D D D. These become therefore powerful electro-magnets, and induce in their turn more powerful currents in the armatures. The larger currents thus produced, again reacting in their passage on the electro-magnets, superinduce a higher state of magnetism in them, and this again exalts the electricity generated in the armatures, and so on until the limit of saturation is reached. The current, after traversing the coils, is led to terminals to which connection can be made for exterior work. It is remarkable that although this discovery was so important, and the description and designs were so clear in the specification, so little attention should have been attracted to it. Soren Hjorth was, indeed, much before his time, many of the machines now doing excellent work being simply trifling modifications of his "magneto-electric battery."

The Siemens Armature.

§ 14. The intensity of electric and magnetic effects does not increase in the simple proportion of the nearness of the bodies acted on, but in a much greater ratio which, in the case of electrified bodies and permanent magnets, is *directly as the square of the nearness* or (what amounts to the same thing) is *inversely as the square of the distance*. For instance, we find that a magnet which exerts a "pull" of 1lb. on a given piece of iron at 6in., if placed at 3in., or *twice* the nearness, pulls with a force of 2 × 2 = 4lb., and if placed *four* times as near, namely, $1\frac{1}{2}$in., pulls with a force of 4 × 4 = 16lb.

It would appear that in the case of electro-magnets, the ratio between the distance and the effect increases even more rapidly, being, according to the best authorities, equal to *inversely the cube of the distance* nearly. Hence, it struck Dr. Werner Siemens, of Berlin, that if the armature could be constructed of such a form as to allow of its remaining always very close to the poles of the magnet during its rotation, greatly exalted electrical effects would result, and in 1856 he patented in this country the special form of armature represented

Fig. 12.



[illegible] Fig. 12a, so well known as the "Siemens" or "[illegible]" armature. On re- [illegible] portion of the armature is exposed to the action of the said poles. The Siemens armature, as shown at Fig. 12*a*, consists of a cylinder of soft iron, between three and four times as long as its diameter, around the sides and ends of which is cut a deep groove or channel, rather more than one-third the diameter of the cylinder. This is shown in section at *b*. The soft iron cylinder, *c*, has brass heads and axes fitted to it, as shown at *f* and *g*—the latter carrying a pulley or *rigger*, by which the armature can be rotated; while the former is encircled by the commutator, *c c*, to which are attached the two ends of the insulated wire, which is wound in the channel. When in action this armature is placed between the poles of a compound horseshoe magnet, and supported on trunnions or bearings at both ends; two springs pressing against the commutator carry off the electricity generated by the rotation of the armature, the motion being imparted by means of a band passing over the pulley at the farther end of the armature. A general idea of this arrangement may be gathered by inspecting Fig. 12 H.

RECOVERY OF PHOSPHATES FROM SLAG.

THE successful attempts made in recent years to remove the phosphorus from iron in the course of manufacture by the basic process have naturally attracted the attention of chemists to the possibility of recovering the valuable manure, phosphoric acid, from the slag. A patent has been recently obtained by Mr. S. G. Thomas and Mr. T. Twynam for improvements in the manufacture of phosphoric acid and phosphates from slag, especially adapted to their recovery from slags produced in the basic Bessemer and Siemens processes. The slag is first finely ground, and the particles of iron picked out by means of magnets; it is then treated with sufficient hydrochloric acid, either in aqueous solution or in the gaseous state, to dissolve out the phosphoric acid together with part of the oxides of iron. The powdered slag may first be roasted in a rotary or other calciner, so as to oxidise the ferrous oxide contained in it. If there be not sufficient ferric oxide present in the solution to combine with all the phosphoric acid, it will be necessary either to add some ferric oxide or puddler's slag (which should preferably have been first roasted), or to oxidise part or the whole of any ferrous oxide there may be present, either by chlorine gas or by the addition of manganese binoxide (in which latter case there must be sufficient free acid in the solution to cause the decomposition of the manganese binoxide and set free chlorine), or the ferrous oxide may be oxidised by injecting air into the solution, or by other well-known means. The solution is then run off from any insoluble residue, and a sufficient quantity of lime or (preferably) chalk is added to it to cause the precipitation of ferric phosphate (magnesian lime or limestone may be used in place of ordinary limestone for this purpose, the magnesia dissolved being afterwards precipitated by lime). The precipitation of the ferric phosphate may be effected in the cold, keeping the solution well agitated; a gentle heat however causes the precipitate to settle down better. When the precipitation is complete the ferric phosphate is separated from the solution by filtration, and washed to free it from calcic chloride. The precipitate is then dried so as to drive off all its water and digested with a considerable excess of sulphuric acid, so as to decompose it into phosphoric acid and sulphate of iron, which latter is insoluble in the excess of sulphuric acid employed. Ordinary chamber acid is able to effect this decomposition, but a stronger acid, such as is obtained when using a Glover tower, is better adapted for the purpose. The ferric phosphate should be kept well agitated in the liquid, which may be gently heated to facilitate the decomposition. When the ferric phosphate is considered to be completely decomposed the insoluble ferric sulphate is separated from the solution containing the phosphoric acid and excess [illegible] sulphuric acid by means of a filter press or [illegible]therwise. The filtrate will be found to contain [illegible] all the phosphoric acid in a free state, with the excess of sulphuric acid, from [illegible] be separated by the aid of heat, the [illegible] driven off and condensed, [illegible] acid practically pure, or [illegible] he mixed acids may be [illegible]huric acid for making super-phosphate of lime. The sulphate of iron precipitate after being washed with sulphuric acid may be decomposed by heat into ferric oxide and fuming sulphuric acid, or it may be mixed with salt and heated to form sodic sulphate. In some cases, when there is no lime in the slag employed (as when treating puddler's cinder), the phosphoric acid is thrown down as a mixed ferrous and ferric phosphate by means of lime without previous oxidation, and is then dried and treated in the same way as ferric phosphate.

PATTERN MAKING.—XVI.

(*Continued from page* 52.)

Miscellaneous Engine Work.

BEYOND the cylinder pattern, the pattern of its bed, and the flywheel, there is nothing difficult or intricate from the pattern maker's point of view. Hence we shall run rapidly through the only items that call for remark in connection with an ordinary engine, comprising them in the compass of a single article.

Double eccentric sheaves, forward and backward, are cast together. The pattern itself consists simply of two plain discs, dowelled together—the grooves being turned out in the casting. But the dowelling together of the discs requires care. Proceed thus:—Say we have an engine with $\frac{3}{8}$in. lap, $\frac{1}{16}$ lead, and $2\frac{1}{4}$in. throw of sheave. Strike a circle $2\frac{1}{4}$in. diam., and draw a line through its centre, Fig. 76, at a distance away from this line = $\frac{7}{16}$ = lap and lead, and parallel with it draw another line. The two points where this second line cuts the $2\frac{1}{4}$in. circle will be the centres of the two sheaves, forward and backward respectively. Strike the circle representing their diameters; lay one disc on the drawing on its proper circle, and dowel the other upon it perpendicularly over its circle, adjusting it with set square. Put the print for the shaft-hole on the pattern for one pair of sheaves first, say right-hand. Cast one off, then remove the print to the other centre for the left-hand.

As small eccentric straps, Fig. 77, are usually made in gun-metal, the grooves in many instances are cut out in the pattern. The neatest way to get out the inside of the strap with its grooves is to turn it; but as an allowance for facing is given in the joint, which makes the pattern $\frac{1}{16}$in. more than a half circle, the straps are turned a half at a time, a false block being screwed on the face plate to complete the circle, its face standing $\frac{1}{16}$in. back from the centre line while the two half straps are being turned in succession. The outside portion, with its lugs for bolting together, is worked by hand away from the lathe. The lug or facing for eccentric-rod, and the oil-cup boss are put on separately. Straps are moulded at pleasure either on their sides or edges—the latter giving, as a rule, the cleanest metal.

Slide-valves of the D shaped type are in commonest use. Gridiron valves, balanced valves, &c., are too simple to cause any trouble to the pattern maker—accuracy being the only important condition. The usual D-shaped valve is the only one that calls for special notice. A glance at the sketch (Fig. 78) will indicate the way in which it is made. The block (Fig. 78) A, forming the inner portion of the valve is planed to width, marked out and worked through with gouge and chisel. The sides B B are also worked to shape and then fastened to the block. The piece C, for reception of the valve-rod head, is fastened in place, and a print for the nut core bradded on. An allowance of $\frac{1}{8}$in. is made on the face D for planing, and the same at ends E E, for accurate cut off; a similar allowance also at sides F F for close fitting into the steam chest.

A D valve, like Fig. 79, is made in a similar way, only that, after the D shape is worked, a half-round piece *a* is glued within, and when dry, the recess *b* for the valve-rod is worked on the outside—the pieces *c c* being fitted and glued round the curve to form the flat edges and ends of the groove.

A valve, like Fig. 80, is made in three pieces, as in the first instance, or cut out of a solid piece of stuff; but the outside, instead of being worked half-round, is partly turned and partly dressed off by hand. Allowance for turning is made also at A, where the eye of the valve-rod slips over.

An ordinary steam chest calls for no special remark, and of a double-flanged one it is sufficient to note that the bottom flange must be left loose from the body. Patterns also for plain,

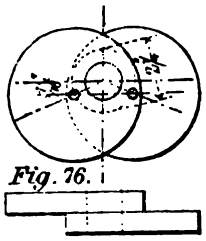


Fig. 76.

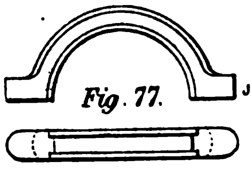

Fig. 77.

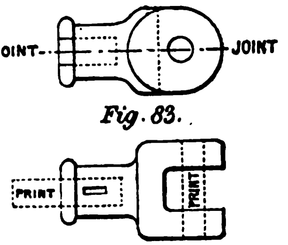

Fig. 83.

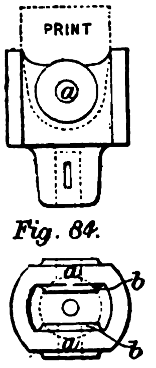

Fig. 84.

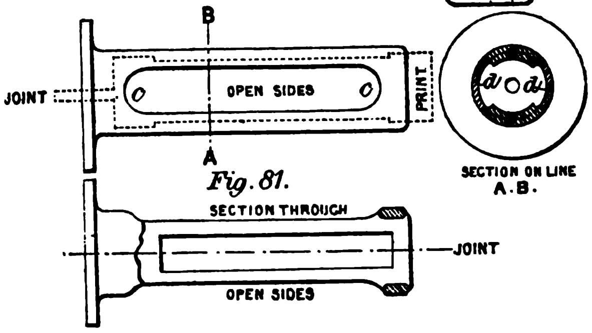

Fig. 81.

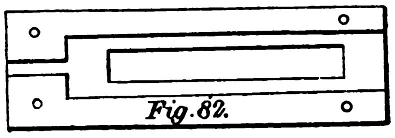

Fig. 82.

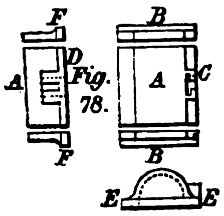

Fig. 78.

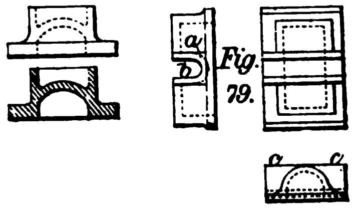

Fig. 79.

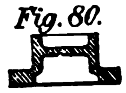

Fig. 80.

flat guide bars are made just like the casting, so we say nothing about them. Instead, however, of the old guide bars, circular guides, bored to receive a circular cross-head, are coming into common use. They are east in a piece with the cylinder cover, have a massive appearance, require little fitting, and owing to the large extent of surface over which the friction of the cross-head is distributed wear for a very long time.

The pattern is made in halves, jointed longitudinally (Fig. 81), and has a print at each end. The open parts of the guide (Fig. 81) C C, are cut in the pattern as far inward as the diameter which corresponds with the body core of the guide (Fig. 81) section, *d d*.

For the core, a box is necessary, owing to the existence of the facings, *e e*, for the cross-head. The box is dowelled in halves, and worked with templets. Fig 82 shows one half, looking into it from the joint.

The cross-head, or head of the piston rod, is of the shape indicated in Fig. 83, when flat guides are used, and like Fig. 84, when it works in a circular guide. In the former case the pattern would be jointed and cut out to the shape of the casting, the holes, if large, being cored with parallel prints. In the latter form (Fig. 84), the inside is taken out with a core, the pattern moulding either on its side or on its end, and requiring no joint. In either case the core box will be jointed longitudinally, and the holes, *a a*, will be cut out in top and bottom boards dowelled on the box body, which boards will also carry the top and bottom bosses, *b b*.

Cranks, brasses, pistons and their rings, slipper blocks, governor castings, except when there is something special in their construction, are too simple to need description from the pattern-maker's point of view; so with this chapter we close our remarks on engine work and pass to other subjects.

THE MAGNETOPHONE.

THE experiments of Bell, Preece, Mercadier, and others on the radiophone suggested to Prof. H. S. Carhart, of Evanstown, Illinois, the possibility of interrupting, or at least periodically modifying, the lines of force proceeding from the poles of a magnet by means of a disc of sheet iron, perforated with a series of equi-distant holes, and rotated so that the holes should pass directly in front of the magnetic pole. It is well known that an armature, placed on the poles of a permanent magnet, diminishes the strength of the external field of force by furnishing superior facilities for the formation of polarised chains of particles from pole to pole. This is the case even when the armature does not touch the poles, but is in close proximity to them. If a piece of sheet iron be placed over the poles of a magnet without touching, and the magnetic curves be developed on paper above the iron, they will be found to exhibit less intense and less sharply defined magnetic action than when the sheet iron is removed. If, however, a small hole be drilled directly over each magnetic pole, the screening action of the sheet iron is modified in much the same way as when a hole is made in a screen opaque to light; for the developed curves show distinctly the outlines of the holes. If, therefore, the sheet iron in the form of a circular plate, pierced with a number of holes, be rapidly rotated between the pole of a magnet and a small induction bobbin, the action of the magnet on the core of the bobbin will be periodically modified because of the passing holes; hence induced currents will flow through a circuit including the bobbin. A disc of sheet iron was pierced with two circles of quarter-inch holes concentric with the disc, the number of holes in the two circles being thirty-two and sixty-four respectively. On one side of the disc was placed a horse-shoe magnet with its poles very near the rows of holes; on the other side were arranged two corresponding induction bobbins. The circuit was completed through a telephone and either bobbin at pleasure. Upon rotating the disc rapidly, a clear musical sound was produced in the telephone, the pitch rising with the rapidity of rotation. Moreover, the bobbin opposite the circle of sixty-four holes gave the octave above the other, and each gave a note of the same pitch as was produced by blowing a stream of air through the corresponding holes. Hence, as a beam of light, focussed upon a circle of equi-distant holes in an opaque disc, is rendered periodically intermittent by the rotation of the disc, and produces a musical tone when falling upon the proper receiving apparatus, so the lines of force proceeding from a magnet may be rendered periodically intermittent in their action on an induction bobbin by a similar metallic disc set in rapid rotation; and the induced currents, arising from the periodic change of magnetism in the core of the bobbin, produce a musical tone in a telephone, the pitch depending in both cases only upon the number of holes passing in unit time.

Non-magnetic metallic discs produce similar musical notes by the periodic modification of the magnetic field by means of the distortion or bending of the lines of force. The solid parts of the conducting disc deflect the lines of force in the direction of the rotation, but upon the passage of a hole they fall back towards their normal position, A periodic movement of the lines of force will, therefore, take place when the disc rotates. Discs of zinc and copper produce a clear musical sound, somewhat less intense than that given by iron under the same conditions. Any discontinuity in the rotating disc recurring periodically will produce corresponding induction currents in the bobbins. Thus, V-shaped notches round the circumference of the disc are quite as efficient as the holes in effecting the requisite modification of the magnetic field. Moreover, it is not necessary that the holes extend entirely through the disc. Two discs of zinc, of the same diameter and thickness, were placed together on the same rotating spindle, one pierced with a circle of holes, and the other not. The combination proved as efficient in producing the sound as the single perforated disc. A sheet of tinfoil, with a circle of small holes, was pasted on the continuous zinc disc. The perforations, extending only the thickness of the tinfoil into the compound disc, constituted a sufficient discontinuity to produce a clear, though somewhat faint, musical sound. About the same result was given by a disc consisting of the same sheet of tinfoil pasted on cardboard. Any periodic variation from uniformity in the disc appears to produce corresponding variations in the magnetic field when the disc is rotated. Depressions made with a punch, at regular intervals, in a zinc disc rendered it a sound-generator when rotated in this apparatus.

Since the pitch of the note obtained depends only on the number of holes passing the pole of the magnet in a second, it is easy to construct a piece of apparatus to illustrate musical intervals. A cylinder of galvanised iron, with four rows of holes in the ratio of 4, 5, 6, 8, was mounted on a whirling table, and provided with two U-magnets and two electro-magnets for induction. The latter were placed inside the cylinder, and the former outside. By means of four keys, any one of the bobbins, or all of them, can be put in circuit with the telephone. By depressing the keys, the four notes of the common or major chord are brought out with great distinctness and clearness. In fact, the intensity of the sounds obtained by the magnetophone is sometimes so great as to be painful to the ear when the telephone is held closely against it. Prof. Carhart describes these experiments in *Science*, and intimates that he is making further investigations.

THE TRANSMISSION OF ENERGY.

I.*

By Prof. OSBORNE REYNOLDS, M.A., F.R.S.

ALTHOUGH the terms energy and power are in continual, we might almost say familiar, use, such use is seldom in strict accordance with their scientific meaning. In many ways the conception of energy has been rendered popular, but a clear idea of the relation of energy to power is difficult. This arises from the extreme generality of the terms; in any particular case the distinction is easy. I was going to say that it is easiest to express this distinction by an analogy; but, as a matter of fact, everything that seems analogous is really an instance of energy. Power may be considered to be directed energy; and we may liken many forms of energy to an excited mob, while the directed forms are likened to a disciplined army. Energy in the form of heat is in the mob form; while energy in the form of a bent spring, or a raised weight, matter moving in one direction, or of electricity, is in the army form. In the one case we can bring the whole effect to bear in any direction, while in the other case we can only bring a certain portion to bear, depending on its concentration. Out of energy in the mob form we may extract a certain portion, depending on its intensity and surrounding circumstances, and it is only this portion which is available for mechanical operations. Now energy in what we may call its natural sources has both these forms. All heat is in the mob form, hence all the energy of chemical separation, which can only be developed by combustion, is in the mob form; and this includes the energy stored in the medium of coal. The combustion of 1lb. of coal yields from ten to twelve million foot-pounds of energy in the mob form of heat; under no circumstances existing at present can all this be directed, nor have we a right, as is often done, to call this the power of coal. What the exact possible power is we do not know, but probably about four-fifths of this, that is to say, from eight to ten million foot-pounds of energy per pound of coal is the extreme limit it can yield under the present conditions of temperature at the earth's surface. But before this energy becomes power it century, who scornfully suggested, as a better explanation, that the fossils which so much exercised the minds of his contemporaries were shells which had fallen out of the hats of pilgrims on their way to Rome. It would be futile to pretend that a natural timidity in the face of bold conclusions was the sole or, indeed, the chief cause which led to the shifty explanations of early writers. There was a reason deeper and more real. That which men had always rightly clung to as their most precious possession was their religious belief, but it unfortunately happened that religion at that time was bound up with a rigid and narrow system of theology, which was at utter variance with all conclusions involving the occurrence of former extensive geographical changes, or a prolonged existence of the stratified rocks. For a long time 6,000 years was the utmost that could be afforded for all the changes that were known to have taken place in the earth's crust. By this period inquiry was limited, thought was not free, and thus for nearly 300 years after the time of Da Vinci the human intellect lay helplessly bound by the enchantments of a dogma which, after all, had no real theological basis. There were, however, at intervals minds over which dogma had no power. The Huguenôt Bernard Palissy, fifty years or so after Da Vinci, arrived at the same conclusion as he had done with regard to the nature of fossils and the formation of stratified rocks, but no great advance was made till 1669, when Steno, a Dane, who was professor of anatony at Padua, by investigations not only went so far as his predecessors' conclusions, but pointed out that the lowest stratum in any group regularly placed one on another was the oldest, and at the time of its formation the overlying beds did not exist; he showed also that strata were deposited horizontally, and declared that some strata which were removed from the horizontal position had had their position changed from the horizontal one after their deposition. This seemed a very obvious conclusion, but amongst geologists the faculty of perceiving obvious conclusions was a rare endowment, as was shown by the fact that 150 years after Steno they were bent on arguing that inclined strata were deposited in the position in which they now occur, and it was not till beds of pebbles standing vertically in the Alps were noticed that these "biind moles" were enabled to perceive the obvious conclusion of Steno. Steno also pointed out that sediment deposited in the sea must be bounded below by what was once the seafloor, and laterally by what was originally the seacoast, an inference far from generally accepted till long after the beginning of the present century. He traced 14 separate strata in the Tuscan valleys, and this with his suggestions as to their geologic history was his great work: shining like a brilliant light he seemed to only render the gloom of the middle of the 17th century the darker. Arduino, in 1760, made another step in the work of classification; he divided the rocks into three groups, primary, secondary, and tertiary, and distinguished between the igneous and aqueous rocks. It was left to Dr. Smith, the father of English geology, to prove that particular groups of fossils definitely characterised particular groups of stratified rocks, a fact of the utmost importance. This had been no doubt intimated by Werner, but Dr. Smith illustrated it and practically applied it by making the first geological map of England. While the phenomena of the earth's crust were thus the subject of more or less successful investigations a search was continually made for some single explanation wide enough to embrace them all. Most of these creeds were crude enough, wretched travesties of the Mosaic account of the Creation. The wild ideas of cosmogonists, who busied themselves in inventing imaginary systems instead of carefully investigating existing facts, had a pernicious effect on the growth of geology, which became lost in a maze of conjecture. A hundred and twenty years after Steno arose the master mind of Hutton, who determined faithfully to explain the records of the past by an appeal to the present. He ascribed the wonderful changes that had taken place on the earth's surface to the action of such natural forces as streams, rain, and air; then the value of time in these changes was shown, and Hutton declared the immense antiquity of the world. Hutton formed the uniformitarian school, opposed to which were the teachings of the catastrophists, in the eyes of whom the condition of the earth proved numerous and terrible convulsions, floods, and earthquakes to have been the operating cause of change. With the death of Sir R. Murchison this latter school became extinct, at least in Britain. Hutton, knowing little of the gradual upheaval or depression of the earth's crust, had to call in the aid of the catastrophist to account for evident changes in the position of strata, and in his view alternating with long periods of the calm, quiet working of natural forces, were sharp convulsive catastrophes, which produced abrupt and tremendous changes. Lyell strengthened the Huttonian doctrines in their weak part, and showed the upheavals and depressions to have been for the most part very gradual, and, carrying the uniformitarian doctrines into the very arena of catastrophism, pointed out that even volcanoes were built up of ashes and lava accumulating round an orifice like a gigantic dust heap. Ramsay removed other difficulties of the system, and showed to what a planing action the earlier formations had been subject by the destructive power of the sea. A map showing the condition of the earth's surface between Usk and the Forest of Dean, for instance, before this planing process, included great elevations—mountains 12,000ft. high, where the ground was now nearly level. The objections to Hutton's teaching were one by one removed; but, victorious as the school proved, it had mistakes. One was that it had nothing to do with the beginning of things; it divorced itself entirely from cosmogony. Lyell made the great mistake of supposing that the forces of the past were not only the same as at present, but in the same degree, and incalculable calls were made on the assets of the uniformitarian school in the bank of time. On this question the much despised cosmogonist had something to say, and Sir William Thomson was able to show that the period since which the solid crust first forced over the molten interior of their planet was not so incalculably long—possibly much less than a hundred million years. All this time other sciences were making great progress; the indestructibility of matter had been accepted; Darwin's hypothesis of evolution had triumphed. In the evolutional school the long-opposed catastrophism and uniformitarianism found a final reconciliation, and cosmogony was once more joined to geology with the benediction of the physicist, while physical geography retained the honourable place allotted to it by Hutton. The history of geology was the history of a number of successive approximations towards the truth; each stage had been a stage of infancy in relation to its successor, and he saw no reason to believe that the evolutionist school of today might not be replaced by that of a far truer system in a no very distant to-morrow. In concluding, Professor Sollas ran over the geological views on the history of the earth, and showed how wide was the field of geological reasearch, and how it embraced within it most of the other sciences.

USEFUL AND SCIENTIFIC NOTES.

Hereditary Short-Sightedness.—Dr. Cohn has, in a recent number of the *Gesundheit*, summarised various statistics on the question of hereditary short-sightedness, which have from time to time been collected by Erisman, Scheiding, Pflüger, and other authorities on the subject. The researches of the last-named writer resulted in the following facts being elucidated as to the percentage of shortsighted pupils:—Public schools: Without predisposition, 8 per cent.; with predisposition, 19 per cent. Higher schools: Without predisposition, 17 per cent.; with predisposition, 26 per cent. The difference of about 10 per cent. in favour of those children without an hereditary predisposition to shortsightedness is, according to Pflüger's opinion, a reliable basis of argument. At the same time, he asserts that this relatively low figure is arrived at after the necessary elimination of those cases where the predisposition has remained latent, and where it is of such a nature as only to become the source of ocular affection under circumstances of an unfavourable character.

Position in Sleep.—A correspondent has called attention to a statement recently made in regard to the custom mentioned in the Jewish writings of sleeping with the head and feet directed to the north and south. Unfortunately there is some discrepancy in opinion amongst those who advocate this position during sleep. The Hindoos, it is said, believe that to sleep with the head to the north will cause one's days to be shortened, to the south will bring longevity; on the other hand, a physician who died at Magdeburg at the advanced age of 109 (*pace* Thoms) declares in his will that he owed the protraction of his term of life to the fact of his frequently assuming the recumbent position with the head to the North Pole, by which means the magnetic currents pervading the globe are enabled to exert a certain influence on the iron contained in the body. Dr. Reichenbach's odylic force seems to have been similar in its fundamental idea with this, and Dr. Rogers asserts that invalid children with little disposition to sleep may be induced to do so by placing their cots due north and south, with the child's head to the north. There may be some truth in this popular superstition, but we think we can recall some occasions where, though the child assumed every possible position in regard to the magnetic meridian, the "od" force, if acting at all, did anything but conduce to sleep. —*Lancet.*

Sodawater and Ice Machinery.—Messrs. Barnett & Foster, of Eagle Wharf-road, N., have issued a new and voluminous catalogue of the machines and appliances used in the "mineral water" trade—a rather elastic term, which covers a great deal nowadays. However, anyone wishing to know what ingenious contrivances are provided nowadays for the manufacture of drinks and for bottling them, will find them in this catalogue, in which everything that can be needed in the most elaborate factory is illustrated and described.

SCIENTIFIC NEWS.

THE memorandum containing a proposal for the establishment of a marine zoological observatory, which has been presented to the executive committee of the Fisheries Exhibition, is signed by nearly every distinguished zoologist in this country, except those having official connection with the exhibition. The proposal asks for a minimum sum of £20,000 to build and equip a zoological observatory, and to provide for the salaries of the director and his subordinates. Accommodation would be provided for, say, six naturalists, who might desire to avail themselves of the opportunity of acquiring knowledge, and who would pay fees for the use of the laboratory and other appliances of the establishment. Many persons will consider that besides the study of marine zoology, the surplus funds of the Fisheries Exhibition should be devoted to establishing breeding stations, at which the more valuable kinds of fish would be artificially hatched and distributed to all parts.

An international maritime exhibition will be held in the Palais de l'Industrie, Marseilles, from Nov. 15 to April 30. It will embrace everything connected with navigation and also the produce of salt and fresh waters. Particulars can be obtained of M. Lorgeas, Palais de l'Industrie, Marseilles.

The Rev. J. G. Wood sails for Boston this week to fill the post of Lowell Lecturer. After performing the duties of that office, he will deliver a course of lectures at the Cooper Institution, New York, and subsequently make a tour through North America.

The directors of the Ben Nevis observatory have published an account of the scheme in a handy form, which serves as a ticket entitling the holder to the use of the new path, by means of which the ascent can be accomplished with comparative ease in about a little more than two hours. The path is six feet wide, and the gradient is nowhere more than one in five.

The Western Microscopical Club held the first winter meeting on Oct. 8th, at the house of Mr. W. S. Gwinnell, F.M.S., F.A.S., the special subject of the evening being the microscopical structure of rocks. Amongst the rock sections were granites, syenites, trachytes, basalts, &c. together with some interesting sands and ooze deposits. A series of drawings of the same was also exhibited, as well as an extensive and representative collection of fossils, containing many fine and some almost unique specimens. Prof. Boulger, F.L.S., exhibited a beautifully-mounted skeleton of the common frog. Microscopical slides, illustrative of rock structure, were shown by Messrs. Gwinnell, Dr. Bartlett, E. Norris, M.R.C.S., and A. W. Stokes, F.C.S. Among the visitors were Mr. F. W. Rudler, F.G.S., Mr. J. Hogg, B.A., Mr. Norris, M.R.C.S. The next meeting will be on Nov. 5, at the house of Mr. William Crookes, F.R.S., when the subject will be "Recent Discoveries in High Vacua."

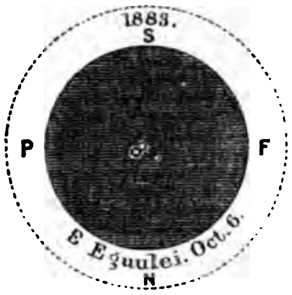
Mr. E. T. Newton, in the October No. of the *Geological Magazine*, describes the recent discovery of teeth of the cave hyæna in the "forest bed" of East Anglia. The relics were found in an excavation at Corton Cliff, Suffolk, by Mr. J. J. Colman. They were associated with remains of *Rhinoceros etruscus*. Mr. Pengelly (p. 102) will probably have something to say about this find, as it must have been known about the time he was delivering his address, in which he took it for granted that no trace of the hyæna had been found in the forest bed.

Dr. Croll replies to Prof. Newcomb and others in the *American Journal of Science* on some controverted points in geological climatology.

A remarkable heat-wave was experienced in Scotland last week, the temperature rising from 13 to 21° above the average of the previous week, and at Aberdeen reaching a maximum of 72°. The temperatures recorded are exceptional so far north in October.

The invitation of the President of the United States, for an international conference on a prime meridian to be held at Washington some time next year, does not appear to have been responded to very cordially. Neither Italy, Russia, Germany, France, or Great Britain have yet replied; Austria, Sweden, and Norway have declined, though the Scandinavian countries approve the

The night being for a few hours after dark exceptionally fine and still, I turned my mirror on that most interesting triple ε Equulei. It is rather singular that both the Herschels observed and measured this star as a double, and missed altogether the fact that it, the chief star, is itself a close binary. It was not till 1835 that Σ discovered that such is the case, and, with a power of 800, elongated the disc, measuring the distance then as 0·4″. Since then the components have separated up to 1·04″ in 1859, while at present, if later measurements are correct, A and B are only 0·83″ apart. I was pleased to find that my instrument, with a power of 250, did more than elongate—separated the discs with a dark line intervening, while with 450 they were resolved into two beautiful suns, well divided from each other. I give a sketch of this magnificent triple as it thus appeared. It is an object, even as a double, interesting; but, with sufficient instrumental power to resolve it fully, very beautiful.



Our attention has also been called to Venus. I have been, like Mr. Franks, observing this planet, and only missed it for a few days when utterly lost in the Sun's rays. Now again I see it very distinctly; but I quite agree with the "Writer of the Astronomical Notes," that as a telescopic object it is most uninteresting, in its present position, and worthy of no more notice in the "Monthly Notes" than it has received.

While writing, may I again ask "F.R.A.S." to kindly furnish us, as he did before at my request, with a correct outline of Saturn as it now appears, with ring as open, probably, as it can be. His former outlines furnished a ready help in the filling up of the details observed from time to time. Looking at Σ 2848 Pegasi, there is a rather wide double, *n. f.*, not mentioned by Webb.

Droylsden Rectory. **S. Mills.**

THE LUNAR CRATER ARCHIMEDES.

[21929.]—I am very pleased to find my observation of the prolongation of the streaks of Archimedes confirmed by such well-known authorities on selenographical matters as the Rev. F. B. Allison (letter 21853) and Mr. T. G. Elger (letter 21877.) Considering that the prolongation of the streaks was noticed by Dr. Schmidt so long ago as 1858 (see Mr. C. Gaudibert's letter, No. 21878); and the frequency with which the above-mentioned observer seems to have seen it, together with the present conspicuousness of the phenomenon, it is rather strange that no mention of the prolongation of the streaks is to be found in the very detailed description of this crater in Neison's "Moon"; or in that indispensable handbook for the observer, Webb's "Celestial Objects."

Now, it would be very interesting to know whether this phenomenon was as conspicuous just previous to 1876—the year in which Neison's work was published—as it is at the present time? For it is just possible that the particular portions of the streaks prolonged beyond the wall (if not the whole of the streaks) may periodically vary in brightness; and thus the phenomonon may not have been sufficiently conspicuous about the year 1876 to attract the attention of observers generally.

I wish to call the attention of our selenographical readers to the possibility of the streaks on the floor of Archimedes being variable, not so much because the hypotheses may account for the omission of all mention of their prolongation beyond the wall of the crater in Neison's "Moon"; but because Mr. F. S. Davenport (letter 21822, p. 61), from observations extending over a period of ten years, considers them to be at the present time unusually distinct; and I estimate the two streaks, to which I called attention in my letter, No. 21706, p. 551, Vol. XXXVII., as being fully ½° brighter than Neison considers them to be.

I shall be glad to learn the opinions of the selenographical readers of "ours" on this point; and I trust that Archimedes may be well examined whenever observable during the next lunation.

Dalston, E. **B. J. Hopkins.**

CAMELOPARDALIS.

[21930.]—Looking at stars in Camelopardalis on Oct. 6th, I found a double not mentioned in Webb. I think it is new, because it is so near two well-known doubles that it would almost certainly have been mentioned if seen. It is about as far following 385 as 384 is in advance of it, and the companion is little more distant than 384, and of lesser magnitude, say, 2·5″ and 11th mag. Position, I did not estimate, not thinking it possible it could be new, but, finding since it is unknown to others who have looked at this group, I now think it probable it may be new. Power used, 570 on 8in. of a 9in. mirror.

Perhaps Mr. Franks will kindly say if it is new, and, at the same time, say what is the most reliable present estimate of distance of 400 Camelopardalis. It appears to me much closer than 1·2″.

Would it be troubling Mr. Franks too much to ask him to send a description of his home-made equatorial stand to the "E. M." I think it would interest many besides **Edwin Holmes.**

COMET PONS-BROOKS.

[21931.]—I beg to call attention to a phenomenon but little noticed and less understood, of which the interesting return of the present visitor has already furnished an example—viz., the variation of its brightness. I did not search for the comet until Sept. 23rd, when I quite failed to detect it with a 3in. O.G. of 4ft. focus, though I was looking at the exact spot where it must have been. The next evening I was much surprised to find it an easy object, so bright that it was distinctly visible with a small telescope, nine-tenths of an inch O.G. and ten inches long. Since then it seemed to lose its light gradually, until my last observation, on the 6th inst., when I could only just see it by averted vision, a small star seen directly through it almost entirely overpowering its light. The present moonlight has prevented any further observations.

Bromley-by-Bow, Oct. 15th. **J. Lane.**

RECREATIONS WITH THE SPECTROSCOPE.

[21932.]—It is a matter of some doubt, I take it, whether amateurs are sufficiently aware of the large fund of instructive amusement which is placed at their disposal by the judicious use of that very wonderful instrument. Speculative astronomy is wont to be regaled with the contemplation of the star-clusters, double and triple stars, and nebulæ which every fine evening discloses, and nothing can surpass their awe-inspiring beauty. But those who possess telescopes of 4in. aperture and upwards may have the extent of their researches largely augmented by adapting a spectroscope of eight prisms at least (5 prisms added to 3) direct vision, such as would be supplied by our most celebrated opticians at no exorbitant cost. I have found such an instrument quite available for the purpose of examining star-spectra of the first, and even of the second, magnitude, and this of itself opens out a pleasing variety. It is also useful in studying the phenomena of the *rain-band* in connection with the pamphlet of Mr. J. Rand Capron. The telluric lines, when the sun is low, are simply gorgeous; and the ever-changing aspects of the few black lines on the red side of the sodium line D show that the amount of aqueous vapour in the air is by no means constant, though not many will be able, I fear, to prognosticate changes of weather with the facility which is anticipated by some who have familiarised themselves with the process. But what has delighted me most, and what I recommend to others, is the simplicity with which exquisite views can be obtained of the solar "prominences." These are included in the chromosphere, and consist of two kinds, "eruptive" and "cloud" prominences. The spectroscope is fitted to the telescope in such a way that the image of the sun (not a very large one) is formed at the principal focus of the object-glass, and directly upon the face of the disc which contains the slit. On applying the eye to the small telescope, there are seen *two* spectra—one bright and solar, the other faint and atmospheric, and these two are separated by a line. This line must be *focussed* so as to be *sharp* and *clear*, and then the slit must be sufficiently closed to show the Fraunhofer lines. It remains next to place the slit *tangentially* to the sun's disc, as seen on the slit (a small mirror is useful for this purpose), and then, on opening the slit to its widest extent, and contriving to keep the sun's image within a hair's breadth from the edge of the slit, and just outside of it there will be seen, on a small scale of course, but yet with remarkable distinctness, a lengthened range of solar prominences, some suspended as in mid-air, and some shooting up fantastically from the solar horizon. The spectacle is one which will not be easily forgotten by those who see it for the first time. It reminds one of the golden tints of sunset, only what is beheld seems more pure and brilliant. In fact, the picture presents a marked contrast to anything terrestrial, and is infinitely more dazzling. On using a telescope of 5in. aperture, the only difference was that the effects were increased in consequence of there being a larger image of the sun in the focus. In other respects the results were the same, and there need be no disappointment. What those observers can show us who are in possession of still larger telescopes, I can only imagine; but an amateur will find far more than he ever expected to find within the compass of his more limited efforts, and I trust many will be encouraged to make the attempt to witness them.

James Pearson, M.A., F.R.A.S.
Fleetwood Vicarage, October 8th.

THREE-MANUAL REED ORGAN.

[21933.]—I send you a sketch of a proposed 3-manual suction instrument, thinking that, if of sufficient merit, it might be useful to "G Minor," p. 69, and of interest to some others. I saw the instrument mentioned by "Organon," p. 92, when in course of construction, but cannot say whether the owner surmounted the obvious difficulties connected with the action, or not, and, if he did, I also should like to know how it was done; but I thought at the time it was a mistake to have to shift or altogether remove any portion of the action proper to obtain access to the reeds. This difficulty at least is removed in the accompanying sketch, and should, I think, receive the first consideration in a large instrument; and then the voicing and nomenclature of the various stops should be decided by actual trial in the various tubes—that is, of course, when anything out of the ordinary groove is attempted. The lowest manual, (1) the choir, is shown in the usual position, with two rows of reeds in front, but may have two more at back if the coupler manual to pedal does not come in the way. (2) is the great, working by backfall and pulldown, like a pipe-organ action? This section may be enlarged almost *ad lib.*, by continuing the pulldown up the wind chest (or outside if preferred) to a second and even third set of pallets and squares, as indicated. (3) is the swell acting by a sticker working through the windchest like the great, on to a tilting pallet as shown. Two couplers only are shown; but would, I think, be sufficient—viz., swell to great, between their respective manuals; and swell octave to great (*a*), a set of skewed backfalls to rise and fall. I think it would be a good plan to make the pedal organ large enough to supply the whole of

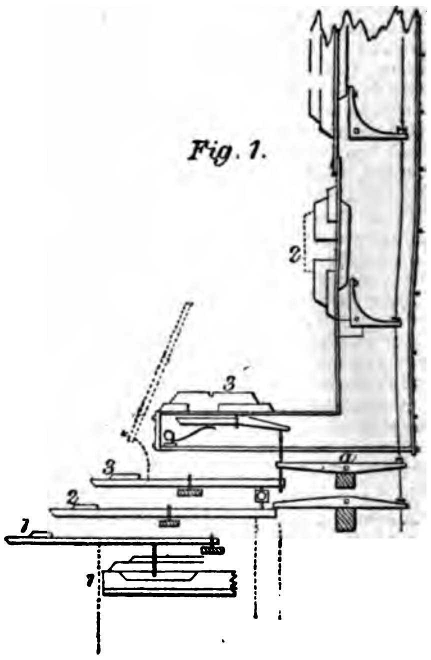


Fig. 1.

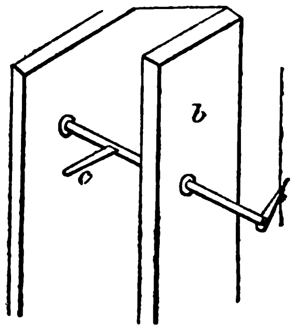

Fig. 2.

not do! The life principle of the bulb is innate, it works, it is capable (as all life is, and this is the essence of life) of appropriating external matter and external energy, and applying them to its own development and reproduction. Sweetness has no existence of its own at all: it is merely an action. The sweetness is not in the sugar, it is a perception by the nerves of taste of some action upon them; there is, therefore, here no "line of reasoning for the disproof of the hypothetical life" for me to admit or to refute.

Mr. Grey says that the materialistic idea has "the merit of unity with what we know of nature." There I most decidedly join issue. Nothing is more certain than the break of continuity in nature at that stage where life is superadded to matter. Mr. Grey will see that his argument from the synthesis of urea is utterly untenable. We all know that energy and the forces play their part in the functions of life, and that the so-called "organic chemistry" is the chemistry of carbon, as carried on in the laboratories of life, and also that it is identical with all other chemistry, but more complex. But no one has, therefore, the shadow of a title to say a word as to the possible synthesis of *life*. It is very possible that we may be able "to-morrow" to make starch for instance: but that would not authorise us to imagine that we should ever make a "starch cell." It is the recognition of this gap, not of degree, but of order, which justifies the belief that some new agent, wholly distinct from matter, but operating upon matter, is the cause of life.

The attribution of this power to "matter" is really "a pure assumption, and, moreover, does not throw any light on the subject." On the contrary, it obscures it because it introduces a complication contrary to all our knowledge of matter. It involves the question, How does matter possess it? Is it a faculty of the *atoms of carbon*, dormant in other actions? If so, how are we to test or prove its existence, if it is developed only where life occurs? Is it a power possessed by matter in the general, but capable of being taken up by the atoms? Then what is the distinction between the two conceptions?

Nature shows us matter and energy: energy is not matter, it is not a property of the atoms of matter; but its own existence is evidenced only by junction with matter, from particle to particle of which it can be transferred. Matter and energy constitute *physics*. Life appears, and appears on this earth after, countless ages of purely physical action. Is it unreasonable to assume that *like energy*, this is a new agent—not matter, nor actions of matter, but operating on matter. That is the assumption of *meta-physics*, "meta" meaning simply "beyond." Why it agrees with the unity of nature. How explain the fact, more certain day by day, that life appears only as a consequence of preceding life?

Sigma.

TRANSFER OF THOUGHT.

[21936.]—"Sigma," in his letter 21903, p. 127, asks me whether I do not see that the quotation from Buchner, anent the production of thought, is nonsense, &c., and again asks me, "What does anyone know about it"? I reply, "'Sigma' does." Has not "Sigma" told us that he knows all about it; that it is an agent working with the senses as a workman does with his tools; or what is all this discussion about? It is no use calling out, "What outrageous trash!" Let "Sigma" calmly marshal his counter-arguments, to prove his "assertions," and I shall be ready to admit their truth, if they be true indeed.

"Jokes" do not constitute proof, nor do they clench an argument. When Buchner says, "in the same manner," it is self-evident to an impartial reader that this means "like"—*i.e.*, as an engine produces "motion" as the result of its activity, so does the "brain" produce "thought" as the result of its activity, although, of course, the "manner" of producing motion by an engine and thought by the brain may be ever so different. It is, no doubt, difficult by a single quotation to give the reader a correct idea of what is its real purport, but I will venture on one more from Buchner:—"The steam engine is, in a certain sense, endowed with life, and produces, as result of a peculiar combination of force-endowed materials, a united effect which we use for our purposes, without, however, being able to see, smell, or touch the effect itself."

Read also what Haeckel says (p. 285):—

"Still, it is often asserted to-day that by these labours only the origin of the human body, but not that of our minds, is explained. In answer to this important objection, we must keep ever in mind the physiological fact that our soul-life is indissolubly bound up with the organisation of our central nervous system. But the latter is composed and is developed in exactly the same manner as is that of all higher vertebrata. Further, according to the researches of Huxley, the differences between man and the higher apes in brain structure are far less than the corresponding differences between the lower and the higher apes. As the function or work of every organ is unthinkable apart from that organ, as function is everywhere developed hand in hand with organ, we are forced to the conclusion that our mental functions have slowly, and with steady ascent, evolved pari passu with the phylogenetic upbuilding of our brain.

"As man has gained a conception of the connection between soul and body, spirit and matter, so the modern theory of evolution goes with its clearer eyesight much further, and teaches us that all organic matter at least, if not matter as a whole, is, in a sense, gifted with a soul. In the first place, improved microscopic investigation has taught us that the structural elements of organisms, the cells have, as a rule, an individual soul life, &c.

"The magnificent and fruitful application of the cell theory, made by Virchow in his cellular pathology, to the domain of theoretical medicine rests on the fact that the cells are no longer regarded as dead, passive building stones in the organism, but as its living, workful citizens.

"This conception is ultimately based upon the study of the infusoria, amœbæ, and other unicellular organisms. For here, in the solitary, isolated cells, we meet with the same outcome of soul life, sensation and consciousness, volition, motion, as in the higher animals composed of many cells, &c. The soul of the plasticule would therefore be the ultimate factor of the organic soul life."

F. W. H.

[21937.]—In common with "Mu." (21905), I have always questioned the utility of semi-spiritualistic performances. I read the articles in former vols. on "Clairvoyance," &c., and the question has always arisen, "Cui bono?" How is it that, with all their pretensions, these learned and clever gentlemen cannot solve a few of the burning problems that have defied the investigations of centuries? For instance, Who was the author of the "Letters of Junius"? Of what trade or profession was Shakespeare?—for has he not been claimed by nearly all of them? Then, again, in modern times, What became of the ill-fated *President*, the *Atalanta*, &c., &c.?—to say nothing of the undiscovered crimes that have startled the present generation. Has any scientific question been settled, any geographical problem solved? I have never heard or read of such. I do not fully share the disbelief of "F.R.A.S." (p. 125); for I have seen a gentleman of unimpeachable integrity, who is peculiarly sensitive of the comments of others, make (to quote the words of his wife, who was present) "a complete fool of himself" before a crowded audience, though, at the same time and place, the lecturer failed to produce any effects (save a little drowsiness) upon—

Lamplighter.

[21938.]—It appears remarkable to those who cannot see in the dark, that "Sigma" should consider Mr. Carter's juvenile friends possessed of rare mesmeric qualities (21856), when the children themselves admit that the "miracles" they perform can be "done" by *all their friends*, and the exception is to find *anyone unable* to do the like (21863). No doubt "Sigma's" opinions are well founded, and, as he says (21903) would be admitted by every sensible person, &c., but "to people of limited scope" it is difficult to understand how a quality can be *rare* when it is *common to all alike*.

SPECIFIC GRAVITY—METALLIC PRECIPITATES—CHEMICAL—OXIDE OF COPPER—PREVENTION OF RUST IN FIRE ARMS—ANALYSIS OF DRUGS AND VEGETABLE SUBSTANCES.

[21939.]—"Specific Gravity" (query 51619, page 23) has been partially answered by "N. C. R." The weight of solid sugar, in pounds contained in one gallon of syrup of various specific gravities is commonly ascertained by means of a table, but for solutions of not greater concentration than about 2lb. per gallon (= 20 per cent.) the strength may be found by dividing the excess of density above 1,000 by the constant 38·5. Thus, for example, the specific gravity of standard wort is 1,057 at a temperature of 60° F. (Inland Revenue Act, 1880). Then the pounds of saccharine matter per gallon will be found by the equation $\frac{1057 - 1000}{38\cdot5} = 1\cdot48$

I am not aware that the density of solutions of silver nitrate and sodium carbonate have been determined. "J. R." will find a different equation or table necessary for finding the proportion of each substance.

"Metallic Precipitates" (query 51779) are not obtainable in all cases. Copper is readily precipitated, as pointed out by "No Sig.," by introducing metallic iron into a solution of a copper salt. A purer product is obtained by using zinc instead of iron. Zinc cannot be precipitated in powder by any reasonably cheap process. Magnesium is said to throw it down. Bronze, having the physical characters of the compact alloy, cannot be obtained by precipitation. But if bronze of the required composition were dissolved in aqua regia, and zinc immersed in the solution, the precipitate would contain both the copper and tin of the original alloy.

The information contained in the query, No. 51556, page 22, headed "chemical," is not sufficient to enable me to afford the querist much help. Surely he does not mean that he extracted from a mineral a white substance, that would burn like magnesium with production of a white light! Yet that is what he says. The blue powder, again, I am unable to identify from the description, but suspect tungsten. Tungstic acid is soluble in alkalies, precipitated white by acids, the precipitate turning yellow on boiling. With reducing agents, such as metallic iron or acid, it gives a blue oxide of tungsten.

"Oxide of copper," query 51597, page 22, can scarcely be made in any cheaper way than by heating the metal. Its preparation from the sulphate would certainly be more expensive, and a good deal less simple. Ignition of the nitrate is a good method; but somewhat expensive as compared with the preparation direct from the metal.

"The Prevention of Rust in Firearms" (No. 51722, page 73) is a subject on which I have no practical experience. Theory would lead me to use a grease free from rancidity, salt, or water. This I should look for in mutton dripping or pure lard. Vaseline I should expect to be very suitable, provided it was originally free from any trace of acid. This could be insured by previously melting it with a little lime.

The "Analysis of Drugs and Vegetable Substances" (No. 51819) is far too long and difficult a problem to describe at length in these pages. A systematic method for the proximate analysis of plant products has been described by H. B. Parsons, and will be found in the *Pharmaceutical Journal* [3] X. 793. Much information on Japanese drugs will be found in the same volume, pages 3, 21, 101, 201, and 261.

Sheffield, October 13. **Alfred H. Allen.**

HYDRAULIC RAMS.

[21940.]—It seems almost impossible to carry further the discussion, as Mr. Davies holds such curious opinions on the subjects of weight, momentum, and such like; but I will endeavour to reply to his last letter as best I can under the circumstances. The effect of using a long supply pipe is mainly this: If we have a vertical pipe 6ft. high, and a similar one inclined at an angle of, say, 45°, the latter pipe will contain, roughly speaking, 50 per cent. more water than the former. Now, the dead pressure per square inch will be alike in both cases; but in the longer pipe there is a greater body of water to resist regurgitation when the valve closes, and thus there is more sent up into the rising main. It is, however, the height from which the water descends which determines the height to which the water can be raised, and I presume Mr. Davies will admit that if there were no fall (however great the length) in the supply pipe, there would be no action of the ram. Mr. Davies appears to refer to momentum as something by itself, instead of merely as the product of weight and velocity—a distinction I fail to understand.

A. S. L.

THE THEORY AND CONSTRUCTION OF THE HELIOSTAT.—IV.

[21941.]—The polar axis being now complete, the sun-pointer may be constructed. In Fig. 2, p. 108, *a c* is a piece of steel rod driven tightly through a small barrel-shaped piece of brass at *c*, turning on centres formed by little screws tapped into the two holes in the rectangle at *c*, the same two holes spoken of while describing the adjustment at the end of the last paper. At *a*, Fig. 2, is shown a little fork fitted on the end of the sun-pointer, holding a little barrel between its prongs, which is bored transversely, with a hole just large enough to allow the mirror-tail to pass easily through it. This fork can turn freely round the sun-pointer; but is prevented from sliding along it either by little nuts screwed (or tightly driven) above and below it; or more simply by tapping a small screw through its shank, the point of which lies in a groove turned in the steel rod. The attachment to set the sun-pointer at any desired angle with the polar axis requires no explanation, but can be seen at once from the figure. The adjustment of the sun-pointer will be much facilitated by fixing either to the steel-rod, or, better, to the clamping-piece, a couple of small sights, the one a little piece of brass with a small hole through it, the other a small circular piece of ivory (a common card-counter). If these are properly fixed with their centres equally distant from the steel rod, when the light of the sun passes through the small hole and falls on the centre of the ivory disc, the rod will point accurately at the sun. The sun pointer should be carefully counterpoised by a weight at its lower end.

Fig. 3 represents a piece of brass which must now be constructed. A and B are two screws forming centres by which the piece (Fig. 3) can turn about the holes in the two pieces *A a′*, Fig. 1, p. 108, on the movable ring. The fork C D E, Fig. 3, is tightly fixed to a steel axis which can turn easily in the end *c* of the piece A B C. It is prevented from moving endways by the same device mentioned in connection with the piece *a*, Fig. 2. The hole in the piece A B C, Fig. 3, within which the axis of this fork turns should be carefully drilled, so that the axis, if prolonged, would pass exactly through the middle point of the line A B. A piece of wire about 3in. long should be tapped along its whole length, and hung to a pivot under the end *c* of the piece A B C. A nut tapped to run up and down this wire and resting on a piece fastened to the edge of the "movable circle" will then give the means of accurately setting the piece A B C at any desired elevation.

If we suppose the centres A B and D E respectively, to be joined by imaginary lines, the distance between the bisecting points of these lines must be exactly equal to the length of the sun-pointer measured from the centre on which it turns, to the centre of the little barrel at its extremity destined to embrace the mirror-tail.

The construction of the mirror and its mounting will be evident from an inspection of Fig. 4. It should be carefully counterpoised by the piece D, Fig. 4, so that when it is set so that the points (B C, Fig. 4) turn around the centres D E, Fig. 3, it may balance in any position.

The heliostat proper is now complete: it only remains to connect it with the clock. For this purpose it must be mounted on three pieces of brass rod tapped at their upper ends into the fixed ring, Fig. 1, and at their lower ends into a triangular plate of brass with levelling screws at the corners. The smaller of the two bevel wheels having been driven tight over the axle of the hour-hand of an American clock, the clock must be fixed to the triangular base-plate, so that the bevel wheels are in gear. The arrangement is shown in Fig. 5, p. 108, which gives a view of the whole instrument.

In Fig. 5 the instrument is shown standing upon a small wooden table. This is for the double purpose of affording space for the pendulum to swing, and of holding a small theodolite compass, as shown in Fig. 5. It is better to attach the compass to the wooden table, as its indications can then be read before the heliostat is placed on the table; and so will not be vitiated by the magnetism of the steel rods. A small circular level attached to the base-plate with three tapped wires with jam-nuts, completes the instrument.

To put the heliostat in adjustment, the following method (though only approximative) will be found accurate enough:—

Place the instrument upon its table, so that the levelling screws fit into countersunk holes made for their reception. Choose a bright starlight night. Remove the polar axis from its bearings, and adjust the position of the instrument until the polar star can be seen centrally through the holes in which the polar axis works. Now screw up the level until the bubble is in its centre, and lift off the instrument. As soon as the compass has come to rest, mark the direction in which it points "Magnetic North."

This having been done once for all, and the clock being in good order, all that is necessary, when the instrument is to be used, is to place the wooden table outside a window, so that the compass-needle lies on the mark, then to place the instrument with the levelling screws in their holes, and to turn them until the bubble is in the centre of the level, then to bring the sun-pointer so that the shadow of the far sight comes on the centre of the ivory disc, and to clamp it in this position; then to turn the movable ring and elevate the mirror until the reflected ray takes the desired direction. This direction it should retain very approximately as long as required.

A. T. Hare.

ELECTRIC LAUNCHES.

[21942.]—I have read with much interest the communications that have appeared in "ours" a few weeks ago upon "Electric Launches" (especially the articles quoted from a contemporary by our esteemed friend Nun. Dor.) with the hope of gaining some valuable knowledge therefrom; but hitherto the articles on the subject have consisted rather of dogma and controversy than real information based on experience.

However intrinsically useful secondary batteries may be, the use of them is impossible pending the erection of frequent charging stations, and as the establishment of these (owing to expense and other reasons) seems generally acknowledged as being so far distant as to be outside practical consideration, we are forced to fall back on primary batteries if we are to utilise electricity for propelling launches at all. The great disadvantage of this system has been considered to be the extravagant consumption of zinc in proportion to the energy obtained, but Mr. Toynbee's experiments appear to have shown that with proper apparatus this is not such a drawback as is generally supposed. The matter is one of such public interest that surely some of the scientific and practical correspondents of "ours" could, if they chose, contribute valuable information which would be of immense service to those readers who are interested in the subject.

I have come to the conclusion, after considerable experience of the application of electricity to motive power, that a great, if not the greatest, element of success is the employment of a motor which shall transmit to the propeller shaft a larger proportion of the electrical energy of the battery than any I have met with yet. To obtain accurate results from any experiment in this direction with primary batteries, with a view to obtain economy of maintenance, very little energy must be lost between the battery and the propeller.

Edward Conry.

SPRING MOTOR FOR TRICYCLES.

[21943.]—In answer to "R. B. W." (letter 21914), who draws my attention to what he very rightly considers a defect in my scheme of a spring motor for tricycles, which appeared some weeks ago in the English Mechanic, I beg to state that the sketch was only a rough one, and was published in hopes that some competent judge might be induced to give his opinion on the main point—viz., whether it would be possible to have a spring sufficiently light, powerful, and long, without being too cumbrous. This I myself rather doubt; but as I have had little or no experience in the matter of spring power, I simply sent the sketch, hoping that some person who had would express an opinion. If it were proved that a gain of power might be derived from such a scheme, then one might apply with interest a little more thought to the construction of details.

The first defect which "R. B. W." points out is, in itself, not so bad as he imagines; but it points to another, and, in my opinion, a worse one—viz., the variableness of the power which would be required in winding the spring. With any spring of sufficient strength to be of any practical use, the greatly increased resistance to propulsion before the spring was actually wound—even in descending the steepest hills—would instantly warn the rider to throw it out of gear. This could be done automatically I have no doubt, or the smash which "R. B. W." fears might be avoided in other ways; but as it would imply more mechanism in any case, if possible one ought to avoid it.

With regard to the other matter—viz., gearing, when the spring is wound, without stopping, if "R. B. W." will examine the sketch, he will see (with a stretch of imagination) that one of the small bevel wheels is intended to revolve upon a ratchet, so that when it is geared to the large bevel wheel (to which the spring barrel is attached), if the large wheel still remains fixed (which it would do until the handle K were raised so that the key F was clear of the key way, and the pin which fixes the barrel withdrawn by the crank *x* being turned round) the result would be that the small wheel would cease to revolve; but the ratchet (which, of course, slides on the key of the axle, along with the other small wheel of which it is part) would continue to revolve; when the spring has unwound itself, the two wheels will again stop until the whole are thrown out of gear.

K. M.

NOTES ON THE CONSTRUCTION AND USE OF THE VOSS ELECTRICAL MACHINE.

[21944.]—An interesting and genuine description of the Voss machine has already appeared (English Mechanic, Vol. XXXVI., pages 285 and 329), by our able contributor, Mr. J. T. Sprague. A detailed description of the machine here would, therefore, be merely a repetition of what has already been done. Having recently constructed one of these famous machines, with some slight modifications, which in performance has more than verified my expectations. The following notes, with the appended experiments, may be of use to those interested:—

The Revolving Disc.—This is of glass, one-tenth of an inch in thickness and 20in. in diameter. It is mounted on a wooden cylinder, 5in. by 3in., through the centre of which a hole is bored, and brass bearings are fitted in each end. The cylinder is turned down five-eighths of an inch at one end to receive the glass disc, which is there secured by a
screw collar. A V-shaped groove is
the other end of cylinder for the cord
wheel to work in. The cylinder
secured on its iron axle by a
which, and the end of
carrying the discharg

used. Before cementing to the varnished glass disc, the zinc circles were wheeled along between the thumb and finger in a shallow tin trough containing some thick shellac varnish. This treatment produces an insulating covering for the edges, and will also serve to cement them on by.

The two inductors are of sheet zinc, and are segment-shaped, with strips attached, to which the curved arms carrying contact brushes are soldered. Each segment, with the inducing paper, is cemented to a separate rectangular glass plate 22in. by 8in.; and a piece of thin glass is cemented over each inducing paper, just leaving the arm carrying contact brush out. It is necessary that an insulating cement should be used for these plates, and unfortunately the best cements for the purpose have to be used hot, which is liable to crack the glass. The following method will perhaps be found best:—Obtain some sheet guttapercha. Cut this into long strips and, after warming them, lay them round the outer edge of the inducing paper, leaving a short interval at the arm. Now lay the thin glass over all, and place the plates on a flat board in a warm oven for a few minutes, when, the gutta softening, will allow the plates to be pressed close together, and when cool they will be effectually cemented.

The glass plates carrying inductors are held at the bottom between two wooden rods glued to the baseboard, and are steadied above by an ebonite ⊣ piece, the end of which is secured to the wooden support carrying axis of machine. The side on which the thin glass is cemented should be kept as near as possible—without touching—the revolving disc.

The knobs holding the collecting combs and discharging rods are mounted on varnished glass supports. This plan was suggested by Mr. Sprague, and is much better than mounting them on cylindrical Leyden jars, as the electricity from the machine can be used either direct or through movable condensers.

Some consideration is necessary in the choice of condensers. The Leyden jar pattern is generally assumed to be best; but in these there is a considerable loss by the electricity passing between the inner and outer coatings, especially in damp weather. I have, therefore, tried another pattern, which is as follows:—Cut three pieces of window-glass 6in. by 3in. To one of these, after varnishing, attach two pieces of tinfoil 5in. by 2in., one on each side, leaving a margin of half an inch of uncovered glass all round the foils. A loop of copper wire is next placed in contact with one foil at one end, and a similar loop is connected with the opposite foil at the other end. Next cement one of the other glasses, as described above, one each side, and the condenser should appear as in Fig. 1. The thickness of glass used in these condensers should depend on (1) the size of the machine for which they are intended, and (2) on the extent of coated surface. As the electricity is much better separated than in the jar form, a greater charge may be accumulated; consequently, this will require thicker glass to sustain it. With the machine described, I have three pairs of condensers which vary in extent of coated surface from 3in. to 10in., and 60in. super.; with middle glasses $\frac{1}{12}$in., $\frac{1}{10}$in., and $\frac{3}{16}$in. in thickness. And notwithstanding this apparently excessive thickness, the effect of one of the condensers, when carefully compared with that of a Leyden jar of equal coated surface, was much superior. Note that the ends of all foils in the above condensers should be round, so as to avoid sharp corners. In the first condensers which I made on the principle, the foils had corners; and once when in use on the machine, the electricity broke through the glass of each condenser at the corners, with a sharp report. This has not occurred since using the thick glass and foils without corners.

Two of the above condensers are required for use in the machine. When used for the spark discharge, they are hung by the wire loops on the discharging rods; and the lower ends are connected together by a stout copper wire, on each end of which a bullet has been cast. This, when not so used, will serve as a discharging rod for Leyden jars.

All the contact brushes in the machine are made of the flexible gilt cord used for conductors in medical machines. And all parts of the machine,
quired to conduct electricity, are well covered
arnish made by dissolving 2oz. of shellac in
methylated spirit.
xpected from the foregoing descrip-
described is a very efficient one,

the discharge between
rs) is from 6in. to
us stream, having
ing the con-

produce a ringing sensation in the ears. On bringing the terminal knobs closer together the discharge again assumes the appearance of a continuous stream.

The machine is, of course, self-charging; but it sometimes requires to be worked for a few minutes before it will act in damp weather. There is also a peculiarity in the action when the machine is worked in a very damp atmosphere—viz., the discharge, instead of being constant, frequently changes in polarity. I have often counted the number of revolutions of the driving wheel between these changes, and they appear to occur at regular intervals; the time of interval being according to the state of atmosphere. In damp air the changes have been as often as once in every 30 revolutions of the disc, whilst in dry weather the change may not occur many times during an hour's work.

Several writers have called attention to these changes; but I am not aware of any explanation given. From the fact that they are not accompanied by any sudden discharge, I am inclined to think that the peculiarity is a necessary function in the action of the machine. When the alteration of polarity does occur, it may be beautifully indicated if we hold a square piece of thin metal (insulated) between the knobs of machine. The discharge will then appear like two horns at the corners of metal at one side; whilst the "glow" is produced at the other corners. This appearance will be reversed with the alteration in direction of current, Fig. 2.

Fig. 1.

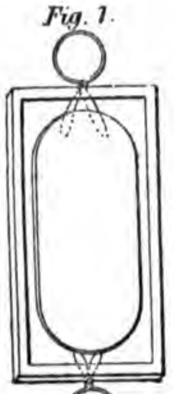

Fig. 2.

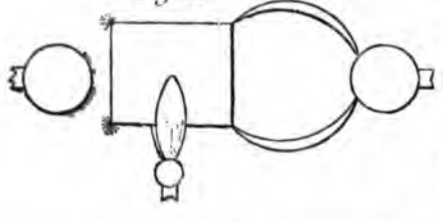


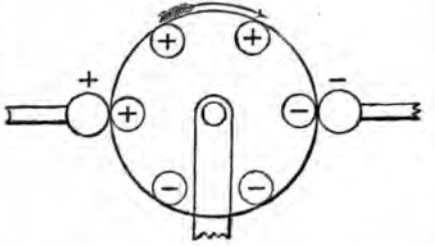
Having thus given a brief notice of some of the essential points in the construction of the machine, I will next mention some of the applications of the machine.

(1) *Physiological Effects.*—If electricity is required for medical purposes, then the Voss machine is capable of supplying it from an effect scarcely perceptible to a discharge which is unbearable. To use the machine for medical purposes, the condensers should be hung on the discharging rods and conductors attached to their lower ends. The discharging knobs should then be brought together, then, by working the machine, and gradually separating the knobs, the effect from the conductors may be increased to the required extent.

(2) *Luminous Effects.*—Beautiful effects may be produced by allowing the discharge from the machine to pass through vacuum tubes, brass chain, designs formed by pasting small pieces of tinfoil on glass, &c. The old and familiar "electrical whirl" is capable of affording a beautiful experiment when used in connection with the Voss machine. I mean the luminous appearance visible when the whirl is worked in the dark. If a whirl is mounted on an insulated axis, formed by driving a pin into the end of a rod of gutterpurcha; then, on bringing the head of pin into contact with one of the knobs of the machine when in action, the whirl will of course revolve rapidly. If it is then seen in darkness, the points of the whirl will appear to form a luminous circle; but on gradually withdrawing the head pin from the knob, so that a short spark passes, then the luminous circle will appear to break up into one of little stars, with *beautiful scintillations.* The effect will also differ with the terminal to which the whirl is held. This experiment illustrates the fact that the discharge from the Voss machine, although appearing as though a continuous stream of electricity, is really composed of a series of separate sparks which follow each other with rapidity. The extraordinary appearance of the metallic discs of the machine when in motion has been shown by Mr. Sprague to be due to the same cause.

(8) *Mechanical Effects.* — Like the dynamo machine in current electricity, the Voss machine is not only well-adapted for the conversion of of mechanical force into electricity, but *vice versâ*; a model constructed on a similar principle is, probably, the best means of converting static electricity into mechanical force. This may be experimentally demonstrated by constructing a small model, by cementing some little circles of paper or tinfoil round a disc of thin ebonite or guttapercha. This, when mounted on an insulated support, and placed between the discharging rods of the machine when in action, will revolve with extreme rapidity (Fig. 3.) The cause of the motion is obviously due to attraction and repulsion. The little discs in the model are not so well under that influence as in their normal position in the machine; but the effect is quite sufficient for a lecture or class experiment. Here, then, we have a static electromotor; and insignificant as the power of such may seem, it is not so, when we consider the small expenditure of mechanical force required to produce the electricity in the machine.

Fig. 3.



In conclusion, I may say that the theory of the Voss machine is simple to those conversant with the rudiments of electrical science; but that which has probably confused most amateurs, is the position of the secondary, or discharging comb, as represented in the several illustrations of the machine which have appeared. The secondary combs should, with their metallic brushes, touch the metallic discs whilst still under the influence of the inducing papers. **Frederick Cowle.**

AMATEUR WIND INSTRUMENT MAKING.

[21945.]—This subject has not received the attention it deserves from amateurs, probably for some of the following reasons:—To produce good results it requires mechanical skill in working both wood and metal, a musical knowledge of, and ability to play, the instrument, without which one cannot tune properly. Good players become accustomed to an instrument, and unconsciously hide its defects; therefore, if playing on a strange instrument, they seldom play as well in tune as their own, yet both instruments would be quite correct with their accustomed players. The difficulty of procuring tools and appliances, of which the number is considerable, is another element: most makers produce their own to suit their requirements, and last, the absence of published works giving sufficient details and explanations. Yet there is no reason why this branch of amateur art should not be as popular as others that have less to show of real value for the time expended on their construction. The following instruments can be made by amateurs, as they do not require any very expensive plant or tools:—Clarionets, flutes, oboes, bassoons, bass clarionets, corni-di-basseto, and cor-anglais. For the present, however, we will confine our attention to the clarionet, as being the easiest to make for a variety of reasons. Clarionets are used in a great variety of keys or pitches, the most usual being A natural, B flat, C natural, E flat, &c. The instrument consists of a parallel tube, ending in a conical bell, the sound vibrations being produced by a beating reed, made of cane, attached by a ligature to a mouthpiece. The entire instrument, excepting keys, &c., is usually made of cocus wood, and although sometimes brass or ebonite clarionets are used, yet the general opinion is that cocus wood or ebony produces the finest tone. Clarionets have a legitimate range of three octaves, though another octave can be got by skilful blowing; it is difficult to control, and not used except in solo music as an effect. Two qualities of tone are produced by this instrument, the lower 11 notes are called "chalumeau," those above this are "clarion," or the true clarionet tones. "Chalumeau" notes are a little like the bassoon, and have no resemblance to "clarion," although the latter is produced from the fingering of the former by slightly reducing the pressure of air and opening a key, which raises all the scale one twelfth. The following is an outline of the clarionet I propose to describe: "An English pitch, Albert Model Clarionet," with 13 keys, 2 rings on lower joints, and patent C sharp arrangement; made in three pieces, viz., mouthpiece, body, and bell, omitting the barrel and middle socket. This enables the low C sharp to be properly placed.

With regard to the mouthpiece, it is best to purchase it, for many reasons, principally because if one tunes a clarionet to a mouthpiece having any slight defect or peculiarity, it may be impossible to correct it afterwards. A mouthpiece, reed, and ligature cost from 3s. to 10s., according to the care bestowed on it by the maker, and also the material it is made of, as to which there is great difference of opinion. As a rule, however, those of ebony are quite as good as any other material. Those made of metal or of glass have now been generally condemned as unsuitable. I may as wel state here that I intend to give the measurement in centimetres and millimetres, as the relationshi between parts is easier seen than by using inch and eighths, and calculations are easier made in t measure. Also I intend to select the easiest wa of construction, excluding tools that are specialiti Those who desire to make a mouthpiece may p ceed as follows: A good hard piece of co ebony is chosen, 4½in. long, and fully 1¼in. A hole is then bored nearly up to C. a ½in. Morse twist drill running in the wood may be first roughly t slight taper, then driven into a ch

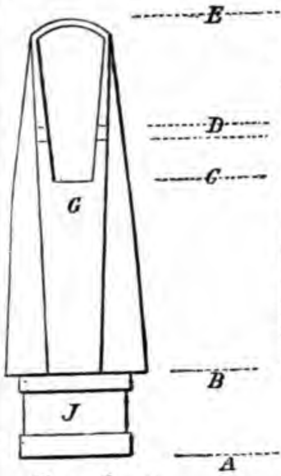


Fig. 2.

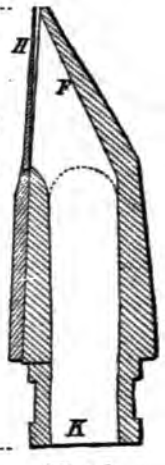

Fig. 1.

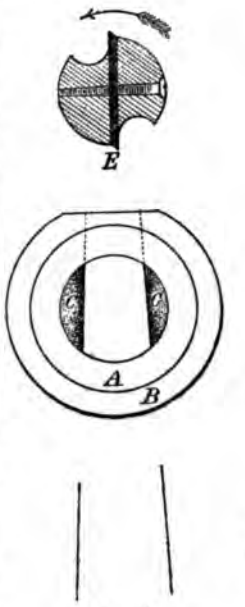

Fig. 3.

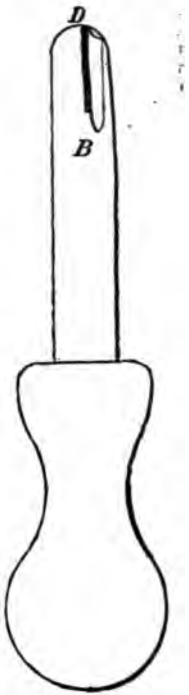

Fig. 4.

foot foremost" between stations, to make up for these delays. It is true they are nominally prohibited from "making up lost time by increased speed," but somehow they usually manage to come in to the minute, even if there has been considerable loss of time *en route*. To accomplish this it is necessary to run at from 40 to 50 miles an hour in places, and this is done without danger or inconvenience. Each carriage is on two bogies, the engine and tender on *four*, so there is surprising smoothness and steadiness even in the worst parts of the road. The American express engines (classes K and Q) work the expresses very satisfactorily, so long as the trains do not exceed seven or eight coaches. I have known an engine of the K class (K 94), keep time on the good part of the road with 12 coaches, the gradient generally being slightly favourable. And I have seen one of the Q class (which differ from K in having cylinders 11 by 18, instead of 12 by 20, both having 4ft. wheels, four coupled), with nine coaches, gain seven minutes on the run of 27¾ miles from Studholme Junction to Oamaru, which was done in exactly an hour, the ruling gradient being 1 in 100, and the maximum speed 48 miles an hour down the banks as against 20 ascending. But, on the other hand, I have several times noticed the more powerful K's having to take a pilot with 10 coaches on a heavy road; and once even on the easy stretch from Christchurch to Rakaia, which has generally rising gradients, but none steeper than 1 in 200, and no curves. That run, however, was timed much faster than the ordinary rate, an average speed of nearly 35 miles an hour having to be maintained, with frequent stops; and I may add that time was equally well kept at a like speed on the same piece of line, and by the same two engines (K 87 and K 88), with 15 crowded coaches. For light express work these engines could hardly be improved; and it is noteworthy that during the past year the eight engines of class K (Nos. 87, 88, 92, 93, 94, 95, 96, 97,) have averaged 34,308 miles a piece, at a total cost of from 0·103d. to 0·111d. per ton-mile; while the two of class Q (Nos. 17 and 51) have averaged 26,377 miles each, at a cost of 0·103d. per ton-mile.

Nevertheless, I must confess myself still unconverted as to the need of sending to America for these engines at a materially increased cost; because it seems to me that either the English "Moguls" (Class J), built by Messrs. Dübs and Co., Neilson and Co., Stephenson and Co., and by the late Avonside Company, or the single-boiler Fairlies, are capable of doing all that is required in the way of speed, while able to pull a greatly superior load. In my last letter, I quoted some notes made by myself on the working of these engines with express trains, and as showing that an almost equally good average speed was maintained as by the American express engines, if a lower maximum was reached. I have several times seen both of these classes working the expresses; and while they kept time just as well as the regular express engines on light trains, they ran with equal punctuality on trains greatly heavier than the K or Q class could have hauled at all in time. For instance, J 107 and J 108 (Dübs), and J 117 (Neilson), kept time strictly on the express with 12 coaches on a heavy road; and J 83 maintained an average rate of 30 miles an hour for 15 miles, including starting and stopping, with no fewer than 20 coaches, the maximum speed being 40. The work of the single Fairlies has already been adverted to. I believe these two classes, with perhaps one lighter type for shunting and branch traffic, would meet all our present requirements; but instead of these three classes we have 23—20 too many. I am strongly persuaded, too, that the double Fairlies have never been quite "fairly" treated in this country. They were worked under distinct disadvantages, with inadequate loads, and then abused for costliness. When they might have been tested with full loads, they were ignominiously relegated to shunting and branch traffic. When engines of special haulage power and flexibility were required for the goods traffic on the heavy grades and sharp curves of the Dunedin—Oamaru section, recourse was had to the American "Consolidation" engines, which to eight coupled wheels add ten more, carrying the pony truck and the double-bogie tender. I am convinced that the twelve-wheeled double Fairlies, double six coupled, with similar tractive force, would have been much more suitable and profitable. They would have utilised their entire weight for adhesion, and would have carried ample fuel and water for the comparatively short runs. But there is undeniably a prejudice against these engines, and so they have never had a really fair trial out here.

Our latest locomotive importations are the heavier single-boiler Fairlies, weighing 32 tons instead of 29, and with 13in. cylinders instead of 12in. These are doing capital work. An order is also under execution in England of additional "Moguls" (Class J), which will differ from the others of their class only in being without flanges on the driving wheels, after the style of the "Consolidation" engines. So far as I can learn, it is intended in future to confine orders to classes D, F, J, and R (see Vol. XXXIII. p. 64), these having proved the most useful types, and capable of performing the utmost variety of work involved in our service as at present carried on, and as likely to be conducted during the next few years.

Reverting for a moment to the double Fairlie engines, and carrying out my previous practice of giving *both* sides of the case as impartially as possible, I think it worth while to quote the remarks of a friend who was formerly in the loco. department on one of our N.Z. railways, and had experience with three of the double Fairlies. He writes:—"In a reply to you (in the English Mechanic, Vol. XXX. p. 118), Mr. Robert Fairlie gave some very low figures as the cost of repairs to his engines, and it at once struck me, on reading them, that he had in mistake treated the two ends of the engines as separate locomotives. Now the Fairlie engines had each *two* numbers (the makers'), and of those which I had to do with one was numbered 1066 at one end and 1067 at the other; the second was numbered 1068 and 1069, and the third 1070 and 1071. At the time of which I am writing they had no other distinguishing, so that a fitter, for instance, in giving in his time would put it something like this:—"Connecting-rod brasses, No. 1071, 4 hours; new piston rings, No. 1070, 4 hours, &c." And so it would appear in the books that the man had been working at *two* engines instead of *one*. I have no doubt that the double Fairlie shows at its best on a line like the Wanganui section, with gradients of 1 in 38 both ways; but on a more favourable line, the single-boiler engine is in every respect more economical." These observations are interesting as coming from a thoroughly practical man, wholly unbiassed. I cannot, however, state, of my own personal knowledge, whether the favourable figures quoted by Mr. Fairlie were or were not based on these somewhat misleading data. Individually I am disposed to believe that the double Fairlies will compare satisfactorily with *any* engine under the conditions stipulated by their inventor—that is to say, full loads and proper expansive working.

I fear my letter is exceeding due limits: my excuse must be the engineering interest of the subject. Our N. Z. experiences are those of a practically new national system of narrow gauge, cheap construction and light rails, steep gradients and sharp curves, with engines specially built—some experimentally—to suit the special characteristics of the road. I feel sure that the results will not fail to be interesting to many readers at home. I may just mention in conclusion that at the close of the last official year (March 31st) we had 1,370 miles of Government railways open, in addition to some 84 miles of private line. The total cost of the Government railways was £10,478,000; the gross receipts for last year £953,000, of which working expenses absorbed 62 per cent., leaving £360,526 as net profit, equal to 3½ per cent. on construction cost. The completed main trunk line of the South Island paid 4⅛ per cent. During the year the N. Z. railways carried 3,283,378 passenger; 1,564,793 tons of goods; 341,186 parcels, horses and dogs; 477,075 sheep, cattle, and pigs. Not a bad result for a population of only just half a million. As to locomotive work, on the South Island Main Line (Hurunui—Bluff), 848 miles, 118 engines ran 2,520,744 engine-miles, at a cost of 9·05d. per engine-mile; and hauled 155,378,070 tons, at a cost of 0·105d. per ton-mile; the 118 engines being 25,294 days in steam.

Charles Rous Marten, F.R.G.S.

Wellington, New Zealand, July 20.

THE PARKER-SMITH BRAKE—TO "IMPRIMATUR."

[21949.]—Having been an *impartial* contributor to the English Mechanic for nearly thirteen years, it is quite unnecessary for me to take any notice of the personalities which have been imported into this correspondence; it should, however, be mentioned that the sole reason why I am *unfavourably inclined to mechanical brakes* is that during the past fourteen years I have had ample opportunities of examining them and seeing their defects in actual practice.

Your correspondent, page 132, devotes the greater part of his letter to an attempt to find fault with air, vacuum, and Heberlein brakes, and some of his statements are very incorrect; but what has this to do with the present correspondence? Even if all the statements of "Imprimatur" were correct, it would not alter the fact that in the Board of Trade Return the Parker-Smith brake is stated not to fulfil the necessary conditions. Several objections have been raised by engineers to the Parker-Smith system. "Imprimatur" claims that the brake is always on, and that a train cannot start till it is taken "off." In practice, however, it would be necessary to have some means provided to keep the brake out of action during shunting operations, and of course there would be the risk that when the train was made up the servants might forget to couple the brake-chain.

There is a great defect in all systems which are applied by the slackening of a chain or wire rope. In *theory* it is supposed that the instant the chain is released the brake will be simultaneously applied, but in *practice* this is not the case; rust and dirt very soon cause the pulleys to work badly and the chain to stick; in winter-time snow and ice frequently render brake-chains and communication cords perfectly useless.

In cases of breaking loose, it is necessary that the brake couplings between the vehicles should part without injury, so that when again connected the brake may be in working order. Now, suppose a Parker-Smith train divided, what would be the result? The chain would be broken, and possibly a portion of it pulled away from under the vehicles.

I was unable to accept the invitation of the Institution of Mechanical Engineers to attend and take part in the discussion upon the Parker-Smith brake last November. Had I been able to do so, it was my intention to have asked for information upon these and other points.

It may be well to mention that many automatic mechanical brakes have been invented, tried, and afterwards removed on account of inefficiency. For instance, in 1869—70, I was invited by Messrs. Wilkin and Clarke to attend trials of their improved system on the Metropolitan and Midland Railways. The retarding force was mechanically developed from one axle on each carriage, and the brake was kept "off" by tightening a chain and applied by slackening it. About five years ago I saw a train on the London and North-Western Railway fitted with a very similar apparatus, but a steel-wire rope was used in place of a chain. In the Parker-Smith system a screw is employed instead of a friction wheel or other appliance, but the principle remains the same.

Mr. Parker-Smith in his paper, and "Imprimatur" in his letter, express the opinion that the "simplest means of securing a result is the best." This may be very true *if the result is secured;* but I cannot for a moment think that the *efficiency* of a brake ought to be sacrificed to so-called *simplicity*.

A continuous brake is a life-saving apparatus, and therefore the great point is *efficiency*. If the only thing wanted was a *simple brake*, surely that can be obtained at once. The old lever brake on coal waggons or the hand screw in guards' vans are as *simple* at possible.

In conclusion, I still maintain that mechanical brakes have had their day, and must now give place to better inventions, but if your correspondent can bring forward any *facts* to disprove this opinion; I shall be happy to consider them.

Clement E. Stretton.

Saxe Coburg-street, Leicester, Oct. 15.

WHAT IS THE BEST OIL LIGHT FOR THE MAGIC LANTERN?

[21950.]—During the winter months I am often occupied in giving popular scientific lectures in the country, and I find the magic lantern most useful in illustrating these lectures; the movable slides in my astronomical lectures seem to be highly appreciated, for the fact is still the same—

> "Segnius irritant animos demissa per aurem
> Quam quæ sunt oculis subjecta fidelibus,"

that is, "seeing is believing."

There is no doubt that for exhibiting pictures on the screen the oxyhydrogen light is by far the best, next comes the oxycalcium; but in both these cases bags of gas are necessary, which in the country are both a trouble to fill, and a nuisance to carry about; but the petroleum and paraffin oils now afford a safe and useful means of illumination. The question is, are we now getting all the light from them that is possible?

We have in the market, two, three, and four-wick lanterns, the light of which is infinitely better than the old sperm oil lamp; but yet I think that possibly if some of those of your contributors who make "lantern optics" their *spécialité*, would give their attention to the matter, the light obtained from these oils might still be improved.

I have been lately using a lantern with four wicks, the light of which is better than any I have had before; but it claims "to give the light of 200 candles," which, as every scientific man knows, is utterly ridiculous.

The puffing advertisements of the "shoptician" do much harm to real science, and in asking for a discussion on the following subjects (as the lantern season has now returned), I should like, with your kind permission, to keep the "shop" out of it.

1. Which is the best of the petroleum or [illegible] oils for use with the magic lantern?

2. What form of lamp, and what wicks, the width of the wick also bein gives the best light in both quantity whiteness of light, and perfect com brought into account?

3. What amount of light in sta really given by the very best oil li able circumstances?

4. In arranging distance of li according to the principle of

source of light is considered as a *point*: how does the fact of the oil light covering a large area affect this?

5. In a lantern with 4in. condensers, is not much light lost by the usual circular slides of 3in. diameter being placed too close to the condenser? Is it not advisable that there should be a means of placing the slide at such a distance from the condensers that all the cone of rays from condenser should pass through it? In square slides this is not necessary. **Rector, F.R.A.S.**

THE BERTHON POWER GAUGE.

[21951.]—It is very desirable that those who use astronomical telescopes should have a ready and accurate means of determining the powers of their eyepieces. Berthon's power gauge is excellent in principle, but my experience of the working of those which have come under my own notice is far from satisfactory.

As I was anxious to know how my 8½in. Calver would stand a very high power, I asked an astronomical friend, who had recently become possessed of an eyepiece which he told me he had measured with his Berthon power gauge and had found to magnify about 830 on a mirror of 6½ft. focus, to lend it to me. This he kindly did, and my mirror, in a good state of the atmosphere, bore it admirably on the moon, δ Cygni, ε, and ε₂ Lyræ, and other objects which I tried. But I thought it did not appear to magnify anything like twice as much as my own highest power, which my Berthon power gauge made 450. So I measured it carefully and found that its power, according to my gauge, was 530. I reported this to the owner. He, fancying that the great difference might be due to some "personal equation," asked me to try *his* power gauge, which he sent me. My result with this agreed closely with his own. Evidently the difference was due to inaccuracy in one or both of the gauges. By placing pieces of wire between the jaws of the slit and noticing the measures of the diameters as given by the two gauges, I found that the results were very different. I next sent the two gauges to my friend; he borrowed a third, and also a Birmingham wire gauge, and found that none of the three power gauges agreed, as the following table of a few corresponding measures will show:—

Gauge A.	Gauge B.	Gauge C.
·200	·188	·188
·100	·104	·094
·120	·026	·014

Gauge A, which was supplied by Horne and Thornthwaite, agreed most closely with the B.W.G.; gauge B I procured of Tuck, of Romsey; gauge C is marked J. T., and was said when purchased to be by Tuck.

Would any correspondent compare his gauge with that of some friend, and see if he finds them agree or not. A gauge to be of use should be correct. Persons possessing gauges which underrate powers would naturally blame their telescopes for not bearing certain powers so well as they should do; and also might accuse the maker of eyepieces of not sending the powers ordered.

T. Perkins, M.A., Shaftesbury.

THE SUEZ AND SIMILAR CANALS.

[21952.]—All are but anticipation of the work of time. Man's agency will but hurry forward that which must come. The ceaseless action of the waves wears away the land in one place to add to it in another. By reference to the map of America, it will be seen at a glance, the approach of the Pacific and the Atlantic, when they join (the two largest seas in the world), it may make a difference to the whole globe. The Pacific may never be so calm, nor the Atlantic so rough again. The British Channel is but a natural one, formed, in the course of ages, by the action of the waves. The similarity of the opposite soils of Dover and Calais, proving, in the opinion of geologists, that they once joined. What change that natural canal has caused to our island history will prove.

H. F.

Product of the Hen.—The hen has in her ovaries, in round numbers, more than 600 egg germs, which develop gradually and are successfully laid. Of these 600 the hen will lay 20 in her first year; 135 in her second, and 114 in the third. In each one of the following four years the number of eggs will be diminished by 20, and in her ninth year she will lay at most 10. In order to obtain from [illegible] the [illegible]

REPLIES TO QUERIES.

◆

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[51203.]—**Music.**—By the reply to the querist "G. F. H." given by Mr. Wm. Jn. Grey, I presume he (Mr. Grey) is unacquainted with the science of acoustics, for it is evident that he does not understand the proper use of mutation stops in organs. Mr. Grey says:—"When we play full to fifteenth, the principal and fifteenth give consecutive octaves with the foundation stops and with each other; and the twelfth yields consecutive fifths with the principal and consecutive fourths with the fifteenth. All these progressions are forbidden by the rules, but the result of them (the progressions, not the rules) is very good." Mr. Grey then concludes that there must be something wrong about the rules of harmony. Now, to understand the proper use of such stops as the principal, twelfth, fifteenth, &c., it must be known that musical tones or sounds are divided into two classes, simple tones and compound tones; that a compound tone is one which has harmonic upper partials more or less present, and that a simple tone is one which has no upper partials; that very few musical sounds are really simple sounds, the majority having upper partials present with some degree of intensity; even the tone of the human voice is classed as a compound tone. It is the presence or absence, and the intensity, of these upper partials which give different qualities to different sounds, and these upper partials are in the same ratio to the prime tone as the numbers 2 to 1, 3 to 1, 4 to 1, &c. That is, supposing the vibration number of the prime to be 16, that of its first upper partial will be 16 by 2, that of its second 16 by 3, that of its fourth 16 by 4, and so on. In tones where the upper partials are absent—that is, in simple tones—the quality is dull and poor; as, for instance, the tone of a tuning fork. In tones having the first two or three upper partials present, the quality of tone is sharp and full. Where the upper partials, especially the first two or three, are loud in comparison with the prime tone, the quality is nasal and poor. Where the higher upper partials are present largely, as in reed pipes of organs, the tone is crisp, sharp, and cutting. It is to strengthen these harmonic upper partials, and so add brightness to the tone, that mutation stops are introduced into organs. Thus the principal strengthens the first harmonic, the twelfth strengthens the second, the fifteenth the third, and the mixtures according to whatever sounds they produce. Perhaps "G. F. H." will see now that Mr. Wm. Jn. Grey's illustration of the mutation stops producing consecutives is erroneous. It is consecutives between primes that are forbidden.—Wm. Archbutt Taylor. Dundalk.

[51228.]—**Deflection of Girder.**—There seems to be no generally acknowledged formula for finding the deflection of girders, so far as I can find: indeed, I do not remember having seen one for iron. But if "J. F.'s" girders are in wood, the following approximate rule may suit his purpose: Multiply the weight (in cwts.) on girder by the cube of its length in feet, divide this by 54 times the breadth in inches, multiplied by the cube of the depth in inches, and the product will give the deflection in inches.—Engineer, Dewsbury.

[51242.]—**Secretary's Liability** (**U.Q.**)—I am rather surprised at this question being left unanswered by the legal correspondents of "ours," as it fairly belongs to them, and is, moreover, of very general interest. I think that "Ireland" would not be liable for the rent of the room; but it might depend upon the form of the receipt. He should take care to have the name of the society (and not his own) mentioned in all receipts. The receipts so made out are good enough for him as against his auditors, and I am of opinion that no personal liability would be incurred. At the same time I do not profess to speak with certainty on the matter, and would like to hear the views of our legal men.—Wm. John Grey, Hon. Sec., Newcastle Rifle Association, Quayside, Newcastle.

[51249.] — **Killing Mice by Electricity** (**U.Q.**)—If ordinary traps will not do, I think matters would not be improved by trying to use electricity; and as the querist is not an electrician, he might get a shock from the apparatus himself. Some people just now seem to have a mania for using electricity for all sorts of possible and impossible ends.—Wm. John Grey, Quayside, Newcastle.

[51251.]—**Sulphuretted Hydrogen** (**U.Q.**)—There is no better way of making this than by FeS [illegible] SO₄ or HCl; I prefer the latter. If a large [illegible] is needed, use a large quantity of material. [illegible]y manage to avoid the smell.—Wm. [illegible]side, Newcastle.

[illegible]**etted Hydrogen** (**U.Q.**)—[illegible] Nai[illegible]" will find a better or cheaper way of making H_2S than the ordinary one—i.e., by the action of H_2SO_4 on FeS. The gas which escapes from the solution submitted to its action may be conducted by means of a tube into liquid ammonia, or any other absorbent; it might also be burnt, forming SO_2 and H_2O, when the SO_2 would destroy any H_2S in the atmosphere occurring from leakage in the apparatus. Chlorine also instantly decomposes H_2S into HCl and S; it can readily be generated by the action of *strong* HCl on potassium permanganate, heat being unnecessary.—W. E. Haden.

[51253.]—**New Zealand.**—The information supplied by "London Stone" is no doubt cheerfully given, but in every case misleading. He apparently never left Auckland, and then makes the ridiculous statement that "his remarks, applying to the colony as a whole, are founded on experience purchased in Auckland." In the north of Auckland the soil is formed mostly of clay, but of such a quality that it only requires cultivation and drainage, which I believe are sometimes necessary in England. The southern part being in a volcanic district, the soil is not the best to be had; whilst in the region of the Thames Valley, where "L. S." seems to have resided, and principally in the region of the Waikato, the soil is very fertile; in fact, from the mouth of this river down the west coast the country only requires opening up. The rain, it is true, carries off the "soluble salts" from the mountains; but instead of taking them to sea, leaves the most of them on the flat lands at the mouths of the numerous rivers. The following may be interesting:—

In 1881, in N.Z.,	
Wheat under cultivation....	324,933 acres.
Bushels produced	8,147,705.
Bushels per acre............	25·07.
The whole six colonies of Australia—	
Wheat under cultivation....	3,051,151 acres.
Bushels produced	23,421,223.
Bushels per acre............	7·64.

Giving at least 200 per cent. better results to New Zealand. In the same way, 75 per cent. oats; 60 per cent. barley.—*Wellington Chamber of Commerce.* As for cold, during an experience extending over 26 years, snow has never remained for an hour on any part of the north island, except on the mountain ranges. Also, whilst on tour over the whole of that island in 1881, from Jan. to Sept., not ten days rain were experienced. This, however, is not always the rule. The houses in the Thames Valley are very likely to be "rocked," as people there go in mostly for gold, and not for building. The weather in Auckland seems to have completely "enervated" "L. S." Why do tree ferns require such "coddling" when brought to England? This climate is too cold, and their sufferings are very evident. Has "L. S." ever met with the native red pine, used all over the colony for indoor work; also, the yellow pine, the strongest woods in New Zealand? Kauri grows only in Auckland, and not below the region of the Thames Valley, where it forms the principal part of the wooded land. Puriri also only grows in Auckland. Totara is used for building purposes, bridges, wharves, fencing, and sleepers. Fences made of it have lasted for 25 years without decay. Seasoning timber for any length of time is considered unnecessary in N. Z., and accounts for the warping. What do the "thin panels" fail to protect one from? The rabbits have had one peculiar beneficial effect; they induced several runholders to break up their property into small farms, or runs, which are sold to settlers. The thirty lines of print about birds, &c., is mostly contained in the quarter column of extracts, which, however, being in a local paper, refer to that district alone, I infer. The exact locality of the writer is not told by "L. S." Finally, he seriously bemoans the fate of New Zealand in being so "splendidly adapted, &c." Now, being a reflective person, and knowing what carriage costs, I am able to inform "L. S." that a ton of goods can be taken by sea, 15,000 miles (England to N. Z.) whilst the same goods would only be taken 500 miles, or less, by rail for the same amount of money. In support of this, how is it that Australian growers find it pays them to send wheat to England, in competition with America, which is far nearer? I think this shows that "L. S." knows little or nothing about the subject. As is the case with other colonies, N. Z. suffers from the affliction of having all kinds of people sent out; to try and get employment in some cases, in others to be rid of a nuisance. The latter are always known by having a profound contempt for colonials in general, and show their profound ignorance of anything in attempting to run down a country which does nothing for them. Even labourers earn from 5s. to 8s. per diem of eight hours; but being better fed, better paid, and better treated, are expected to work well. Moreover, from the mildness of the climate, and the small proportion of population to land, there is always labour for those who are willing to work. Capital is not a necessity if outfits are brought out, but is useful for land investments, which become more valuable every year, as the Crown land decreases and the land passes into private hands.—Joulad.

[51290.]—**Making Glass Impervious to Steam** (U.Q.)—It is news to me that glass lets steam through. I thought it was used for the boiler gauges of locomotives. Will "Edgar" explain more clearly what he wants?—Wm. John Grey, Quayside, Newcastle.

[51398.]—**Black** (U.Q.)—As no one else attempts to answer this, I beg to submit the following recipes taken from a book entitled "New Facts" in my possession. I send it for what it is worth. "Another process for dyeing black, which also produces good results, is the following:—Prepare a bath containing 1lb. of logwood extract and 5oz. fustic extract, which is sufficient for 10lb. of yarn. The yarn is to be boiled with this compound for about 15 minutes and left to stand overnight, next morning the yarn to be lifted out, wrung, put into a bath containing 4oz. bichromate of potash and 20oz. bluestone and worked therein for about 15 minutes; it is to be lifted out again and wrung. To the above logwood bath 2oz. of crystal soda are to be added, after which the yarn is put in and worked about for half an hour and lifted out and wrung, and again put into the bichromate bath for 15 minutes, to which is previously added 2½oz. copperas. The yarn is to be wrung as before, and, lastly, it is to be returned to the logwood bath, wherein it remains for half an hour. After being well saturated it is to be lifted out, wrung, and dried without washing. To give this black a nice bright finish, it has to be passed once more through the logwood bath, to which has been previously added 1oz. of olive oil mixed with half a quart of water and 1oz. soda ash." The article from which this extract is taken is headed "A bright and very deep Black for Cotton," and another process is given which I abbreviate:—8lb. logwood extract, 1lb. quercitron, boiled for half an hour. In this liquor dissolve 1lb. bluestone. Put yarn in this dye bath while hot, work about for half an hour, then raise temperature of bath to boiling point; let yarn remain in half an hour longer. Prepare second bath: 1lb. bichromate of potash, ¼lb. stone salt; put prepared yarn in this, work well about, and when cool wash yarn well in water. The second bath should look a nice brown colour, and if too black a small quantity of bluestone must be added to it. Bluestone is sulphate of copper.—Codadad.

[51520.]—**Granule Carbon Battery.**—The Grove or Bunsen battery is about the best "Nill" can use to light his window if he must light it with electric light, or he might try a bichromate with Trouvé's solution and very large negative plates; but it will be expensive, whichever battery he uses.—Watt.

[51543.]—**Reversion** (U.Q.)—If querist will state his case more clearly, I will try to reply.—R. Hannen.

[51559.]—**Tonnage of Steamers.**—I am not sure that I understand this query—as to the information required,—and as I mistrust my recollection of the difference between spar-decked and awning-decked vessels, I would point out to the querist that he can see "Lloyd's Register" at the "Jerusalem," or at the office in White Lion Court, Cornhill, or for the matter of that, at any shipping office almost, or marine insurance brokers. A reference to the regulations will give him all the information he requires, whatever that may be.—Nun. Dor.

[51570.]—**Blacking Machinery.**—None is required.—J. M.

[51576.]—**G. E. R. Engines.**—Presumably "Buff" means what are called "Mogul" engines. They have been described in back numbers. These queries about locomotives are really very interesting to about six people; but they take up an awful lot of room, and must, I should imagine, be expensive. Take the cut on p. 131 for instance. Possibly the improvements in engine 611 are something wonderful, but as they are not stated, and the drawing resembles engines I saw on the G. E. line certainly ten years ago, I would ask what purpose is served by Mr. Brewer's sketch. The details that would be useful are missing; it is, however, satisfactory to have Mr. Brewer's assurance that the engines are "very neat and well finished."—N. E. Child.

[51578.]—**Rhinoceros Horn.**—Very doubtful whether the walking stick is made of rhinoceros horn; but horn can be softened by steaming or soaking in boiling water.—N. E. Child.

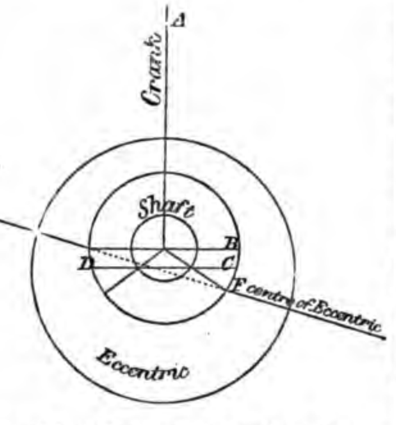
[51584.]—**H. P. of Engine.**—This query is answered in every back volume, and in the text-books and pocketbooks. "Exon" will have to assume a speed, as the number of revolutions is an important item in the calculation. If by "baffle-plate," he means bridge, it is to help heat the gases and prevent them flowing direct into the tubes without combining with oxygen.—Nun. Dor.

[51586.]—**Windmill for Pumping Water.**—What is the difficulty? Connect the pumps direct to the shaft, and make the windmill horizontal or vertical to suit the situation.—Nun. Dor.

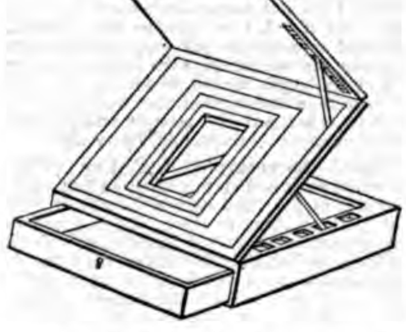
[51594.]—**Crystoleum Painting.**—Look on p. 597, No. 936, and refer to the index of the last volume.—J. M.

[51632.]—**Vaccination.**—"W. M." has omitted to state if his child has been vaccinated with cow-pock virus, or with a scab taken from some kind (?) fellow-being. If vaccinated with the latter, then "W. M." better inquire in what state of health the party from whom the scab has been taken was at the time of vaccination, and report.—Animo Complecti.

[51645.]—**Positions of Eccentric Sheaves.**—To "T. F."—Thanks for your reply. There are a few points I am not sure I understand you about. The inclosed sketch, I hope, will help to explain. (First) Ought not the crank to be on top centre or bottom, to commence with? (Secondly) You say I am to draw centre line through eccentrics. I have shown one eccentric on shaft cutting line at F—is this as you mean? Now, it seems to me there must be a proper place to draw the lines through eccentrics, either the widest or the narrowest part; and that this line must of necessity be marked through both eccentrics at the same place, else the one eccentric will work differently to the other. Would you kindly explain positions, &c., and oblige; also say what is the best kind of link motion?—A. S.

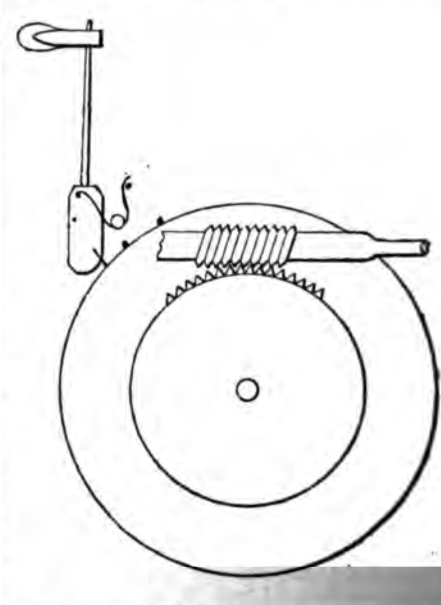


[51733.]—**Retouching Negatives.**—In the first place you require something in the shape of a retouching desk, a sketch of one of which is annexed, but which may be simplified by the omission of the drawer which is intended for the reception of the leads and other etceteras, and by the substitution of a sheet of finely ground glass for the frames for holding the negatives. A sheet of white paper, cardboard, or other material should be placed on the bottom to reflect the light upwards through the negative, and an opaque cloth thrown over the head of the operator, and the top of the desk to keep out light from the sides. You will also require an assortment of lead pencils of various degrees of hardness, some fine sand or glass paper to sharpen them upon, a small sable or camel-hair brush, and some Prussian blue. If you use gelatine plates the retouching may be done on the surface of the gelatine, but on the whole I think it is best to varnish them first. If a soft, retouching varnish be used, no further preparation should be required, but an ordinary hard negative varnish usually requires some preparation either with one of the retouching mediums sold for the purpose, or by roughing the surface. The latter may be accomplished as follows:—Take an old or spoiled plate and rub up the varnish with a piece of glass paper, then take a little of the fine powder thus produced on the tip of a finger and rub it gently over the part to be retouched. The pencils should be ground to a very fine point, the wood being cut away and some half inch or more of the lead laid bare. Then having struck off a proof from the untouched negative, note carefully what marks require removal, what shadows softening, and high lights strengthening, and work on the negative accordingly. Should there be any pinholes, or other marks too deep for pencil to remove, touch them out with the brush and a little of the Prussian blue.—W. Robinson, Jun.



[51756.]—**Cartridges for Martini H. Rifles.**—Weigh out 85 grains with any weights at hand, be sure that 85 grains are in scale, pour into case, strike the case slightly on a piece of board to settle down powder, put in a cardboard wad, then a disc of wax, place two cards on top and press all gently home; put in a papered bullet and seal firmly on the wad and the thing is accomplished. I see that "Artillery Man" states in last "E. M." that the cases are not solid drawn. He is mistaken: they are solid drawn brass shells, and these are the only description that can be successfully manipulated for home filling. The Government cartridges are lapped latteen brass for the sake of cheapness. All small bores are fitted with solid cases, and the Martini is no exception. My cases for Sharp, Remington, and Martini are of this class, and can be used over and over again. If "T. H. H.'s" cases are solid, he will be able to remedy a grave defect which exists in the Government cartridges—viz., the absence of a felt wad, such as used in other better served Sb.'s I punch out of ordinary shot gun wads a wad to fit bore of rifle ·450, and place it on top of powder before I put in cardboard wad. This wad, following the wax wad, effectually cleans out the fouling, leaving the barrel in as good condition after a hundred rounds as it was the first shot. Another advantage the solid case has over the Government case is, the bottle shape of the solid perfectly fits the chamber in the reduction from ·577 to ·450, the mouth of the solid drawn also fits the papered bullet, and no creasing tool to tighten the cartridge is required. Curtis and Harvey's powder, of the brands I mentioned before, is the proper powder to use. Buy all requisites if you can get them; if you cannot, then get a punch to fit bore of rifle, and proceed as follows:—Punch your wads out of hardest cardboard; get two penny candles—one wax, the other tallow—melt, and pour into a tin tray, cover the bottom about ⅛in. thick, and with punch or solid case cut out the lubricating discs. I hope "T. H. H." will now have no difficulty in filling his cartridges. Should he be in any doubt, if he advertises his address I will send him sample of case, wads, &c.—Eccentric.

[51774.]—**Piano Hurdy Gurdy.**—"R. E. S." has set himself a somewhat difficult task, and one which I think, before he has accomplished it, he will consider worthy of a more euphonious title. The action of a mechanical piano is not easily illustrated, but perhaps the accompanying sketch (drawn to a scale of about 1 in 6) will be useful. The position and length of strings should be the same as in a piano, though he may humour the scale to suit the number of tunes required. There ought to be nine notes to the octave—viz., the diatonic with the sharps of F and C, other accidentals being added where necessary. The lower two octaves may be bichord, the next two trichord, and the two top octaves with four and five strings respectively.



(which number prove, as was done at D in the foregoing example), then the 4th wheel must be 72. Now prove the whole train thus: $\overset{c}{64} \times \overset{3rd}{60} \times \underset{4th}{72} \times \underset{Escape}{30} = 8,294,400 \div \underset{Pinions}{8 \times 8 \times 8} (= 512) = 16,200$, as should be. If 4th wheel should not be seconds, work the numbers as before. Should they be, for example, c 80, 3rd 64, escape 15; 3rd and escape pinions 8 each, then 80 × 64 × 30 = 153,600, ÷ 64 = 2,400) 16,200 (6·75 = the ratio or times the 4th pinion is contained in 4th wheel; now 8 is the most likely, so try it:—8 × 6·75 = 54 for the 4th wheel, and gives 16,200 per hour, when by the product of the 3rd wheel, 80, 64, and 30 ÷ the product of the three pinions of 8 each. The next thing to do is to find the diameters of the missing wheel and pinion. Now this is very easy when you know how, but you want two very necessary instruments—a depth tool, and a vernier inch gauge, usually called a thousandth of an inch gauge; it will measure to $\frac{1}{1000}$ of an inch (every watchmaker should have one). Now with the depth-tool take the distance from 3rd to 4th hole; this is called the pitch line, and knowing the numbers of the wheel and pinion, from the P. L. can be calculated their diameters. Rule: Add the teeth of wheel and pinion it drives together, take half the sum, then say As half sum : P. L. : : wheel teeth + 2·25 : to its diameter; and for the pinion, put its number of leaves + 1·5 in the third place, and its diameter will be the fourth term. Ex. Let 3rd wheel be 60, 4th pinion 8, P. L. $\frac{4}{10}$in., then 60 + 8 = 68 ÷ 2 = 34; then as 34 : ·400 : : 62·25 : 73,235 = 3rd wheel's diameter; for pinion say as 34 : ·400 : : 9·5 : ·1111 = pinions diameter; the 4th wheel and escape pinion is worked the same way, only the P. L. must be taken from escape hole to 4th. Note: Three places of decml. will be quite near enough; then, if the 4th be an 8 or 9, increase the 3rd decml. by 2 or 1 $\frac{10}{1000}$. The number and diameter of a pinion can be found to suit a wheel when it has been pitched or geared, for, having the P. L. number of the teeth of the wheel, also its diameter, the rule is, as the number of the wheel teeth + 2·25 is to its diameter, so is the P. L. to half sum of wheel and pinion. In the last case the 3rd wheel is 60, P. L. ·400, diameter of wheel 73,235. Now, ·73,235 : 62·25 : : ·400 : 34, and as this is half sum, and wheel is 60, the pinion must be 8, as 60 + 8 = 68 ÷ 2 = 34.—R. E. B.

[51854.]—**Legal.**—As you have covenanted and agreed not to carry on, or be engaged in, the trade or business of a hot-water engineer, you cannot do so in any way whatever. If you do, you render yourself liable to action for breach of covenant, of which the purchaser can claim specific performance.—G. Russell Pridham.

[51857.] — **Mushroom Bed.** — Procure fresh horse droppings from day to day till enough has been collected to form a bed of the required size. Spread the manure out under cover, and turn frequently, so as to prevent the manure from overheating; if it is found that the centre of heap has become so hot as to turn white and mouldy, turn twice a day, bearing in mind that this appearance is an indication of the manure becoming spoilt. Only the short droppings should be collected—the straw should be carefully shaken out. When enough of the droppings have been obtained to make the bed (which can be made in a cellar, stable, or any outbuilding, by standing up some planks on edge for the outline of the bed), the manure should be firmly trodden or beaten to a depth of 15in. or 18in. The bed in a few days will begin to heat; place a thermometer in the bed; when the temperature has declined to 85° Fahr., break up the spawn into pieces about the size of hen's eggs, and dibble them in about 6in. apart; cover with about 1in. of any good soil, and place a covering of hay to the depth of 4in. over all; if in a place where the bed is likely to become dry, examine from time to time, and water if needed. In about six weeks, if you have carefully followed instructions, the mushrooms will begin to show as white threads of spawn, with small clusters of the fungus. Keep covered, and from day to day examine, and gather when large enough. If in the winter season, the shed or outbuildings should be kept as warm as possible. The temperature recommended is as near 60° Fahr. as can be maintained; but this temperature is only possible in a properly-constructed mushroom house. If the correspondent wants genuine information and details of the profitable cultivation of the mushroom, let him get "Mushroom Culture," *Journal of Horticulture* office.—W. B. Wicken.

[51866.]—**Wimshurst's Influence Machine.**—Put 12 or 14 sectors on each plate, ¾in. broad at their wide ends and ¼ at their narrow ends; length about 3½in. Cut them out of thick tinfoil and stick on with shellac varnish. I use shellac to stick the plates on to the wooden bosses. Electrical cement is also used. A metal spindle is quite as good as an ebonite one. Varnish the plates with shellac varnish, after having carefully warmed them till they are just hot enough to hold easily. The rod carrying brushes would do screwed on to the frame, but would not be so convenient. The collecting combs should be 3½in. long, and three-eighths of an inch from the plates. I think it is hardly necessary to occupy space with a drawing of the sectors. They should be the shape of isosceles triangles with the corners rounded off.—Oudeis.

[51872.]—**Bees.**—(1) Transferring is often done after September and before April if weather is warm and circumstances make it advisable; but it is better done before the former time or after the latter for general reasons; one is that after September they will not be so likely soon to fasten combs into frames, not being inclined to wax-making, and winter coming on, and early in the year they should be breeding fast and combs heavy. (2) From May to October. I should say it would with bees you name, as queens are to be got cheaper now; but care will be necessary in introducing her caged for 48 or 56 hours. (3) I do not know if you could get them in Ireland, but they are advertised by bee dealers, in England, at 5s. or 6s. this month. (4) They do, if not required for comb building. (5) Bees do not under any circumstances change syrup into honey. They will store it and after evaporation seal it up like honey, but although it seems to answer their purposes as well as honey, it always remains the same syrup. (6) To prevent it recrystallising, I do not know if cream of tartar will do better. I have never used any combs sagging. This was my experience last year. My remedy is, secure the foundation well at top, and put in bars of comb in alternation with foundation. (7) I never found eggs in extra-sized cells (by which I suppose you mean drone cells) other than drone, which are considerably larger than workers. Do you mean drones? (8) Red deal, I think. (9) I have not been to Manitoba, but should think it a good part for bees. Write to the Editor of *British Bee Journal*, where you will get this query answered.—J. I. S.

[51873.]—**Fir and Deal in Specification.**—The reason why all fir should be "best crown Memel" is because it is considered to be the best for the purpose, and the same may be said with respect to the deals mentioned. To know "the difference" you must go through the mill.—W. Hopper.

[51874.]—**Stone in Specification.**—This simply means what it says, and says what it means. Any mason will show better than one can tell you. The specification appears a very proper one, and is correctly expressed. What is it that you really want to know?—W. Hopper.

[51885.]—**Wages.**—The agreement, not being stamped, is not binding. He is a weekly servant, and a week's notice is sufficient on either side therefore. After he has entered the service of another person, he cannot claim free use of the land. Now that he has given notice, the crops, as they form parcel of his wages, become the property of the first master, and his right has ceased and become void.—G. Russell Pridham.

[51885.]—**Wages.**—In this case the use of the land, which is distinctly stated to be potato ground, is part of the wages, and obviously it does not count as wages until the crop is lifted, the time of lifting being known to a fraction of a year. "Diago" has the simple remedy to pay the proportionate value of the crop in wages, plus the cost of seed and manuring; or the alternative. He should not make such agreements, or if he does, should distinctly state on what tenure the land is used. It is preposterous to talk of the ploughman "getting wages while working for another man"; his crop is simply wages not received until it is lifted.—Nun. Dor.

[51889.]—**Hammering Cast Engine Rings.**—In answer to query on the above, "A. S." says you cannot hammer cast piston rings. I beg leave to differ, having hammered scores out to the extent of 1½in. or more. Experience in a loco. running-shed will convince anyone that he must find a way to make rings fit the cylinder after a few months' wear, without getting new ones, even if the cylinder is not round.—Griffiths.

[51892.]—**Substitute for Beeswax.**—The best substitutes for this are ceresine and ozokerit waxes. They are about half the price of beeswax. But if "J. R. W." used a small percentage of this in his dressing, and can buy in good parcels, say one cwt., I should advise him to stick to the real article, as he will find it more than doubly effectual in the properties he speaks of. Bleached beeswax is now about 160s. per cwt. It is, however, easily adulterated, and the adulteration is hard to detect. If he finds any difficulty in obtaining pure wax at price named, I will communicate with him if he publishes address.—Guernsey Cave.

[51895.]—**To Soften Old Files.**—Place them in the hollow of a clear fire till they are at a dull red heat, then take them out and bury them in the ashes underneath the grate till they are cold.—S. Austel.

[51899.]—**Medical Coil.**—Many thanks to "Os." for his kind offer to let me see his coil; but I think I know the instrument he refers to. Opticians say a smallest bottle battery will excite it sufficiently to knock a horse down: but a trial brings the power down to a very small figure. What size zinc in a bichromate battery do you require to make the power mentioned? "Watt" and "Sigma" contradict each other, but I suppose the latter is, unfortunately, correct. With regard to the thermopile, I omitted to state in the original query (page 117) that it was for a missionary and physician in tropical Africa, where heat is more abundant than bich. of potash, and it would be very difficult to get the bichrome from England. Therefore, if "Sigma" will give a short description (and cut if needful) of a pile that would give sufficient power (or the names of a few books on the subject), I shall be much obliged.—Thor.

[51904.]—**Lead Keel for Model Boat.**—The practice is to place most weight at the rudder post, which cocks the bows up in a calm, but when under a breeze it has a tendency to rise at the stern. A matter for experiment.—S. Austel.

[51905.]—**Tool Cabinet.**—Thanks to Mr. Best for his offer, and in reply to his query, the tools are carpenter's.—Wave.

[51908.]—**Shakespeare and the Stars.**—Permit me to hazard a conjecture. The "wat'ry star" alluded to seems to me an astrological allusion. This being the case, reference may perhaps be made to the planet Venus, to which the astrologers ascribed a particularly moist and fertile influence; or it may be, one of the "watery" signs is meant, either Cancer, Scorpio, or Pisces. In the former case, the "nine changes" might betoken the apparition of Venus as morning and evening star respectively, the Copernican doctrine having been promulgated before Shakespeare's time. If, however, one of the signs of the Zodiac is intended, the "changes" may refer to their periodic appearance in the nocturnal heavens. Shakespeare is not destitute of what smacks of astrology. For example, a personage in "King Lear," descanting on celestial influences, exclaims, "Tut, I should have been that I am, had the maidenliest star in the firmament twinkled on my birth."—Arthur Mee.

[51912.]—**To Violinists who are Mathematicians.**—No, nothing of that kind has been invented yet. All instruments are tuned by ear. I have tried for many years to find out some means to enable me to construct what I will call an indicator, but have not got any nearer as yet. I thought those telephone inventors might give me a hint towards its realisation, but it has not come about. What I mean by an indicator is a little instrument which would sound or show quite plain when the string vibrates the note required. It is well-known that a tuning fork or other things in a room sound when a certain note is produced, but are not affected by other notes of a different pitch. Although it seems very easy to construct an instrument of this kind, yet I have not been able to do it. I hope that some of "ours" will take it up and be more fortunate.—J. H. Schucht.

[51927.]—**Boilers.**—To "Boswell."—"Young Engineman" will find the formulas given by me to "The North" are as simple as they can be, but I will try to further explain. The tensile strength of boiler plate-iron is generally taken as 20 tons per square inch, 1 ton being = 2240lb. Now the formula is

$$\frac{\text{Tensile strength of the plate in pounds}}{\text{diameter of boiler in inches}} = \text{bursting pressure per square inch.}$$

Now in this particular case it is $\frac{20 \text{ tons} \times 2 \times \cdot 5}{83}$ = bursting pressure of solid plate, or, in other words, ½in. multiplied by 2 × 44,800 = 44,800lb., the total power required to burst the boiler longitudinally, supposing the joints to be as strong as solid plate; but as we know that joints single-riveted are only 56 per cent. the strength of solid plate, and double-riveted joints are 70 per cent., we must again multiply the above result by strength of joint. As particulars of joints are not given, I will suppose them to be double riveted, and then the formula is as follows:

$$\frac{\left\{\begin{array}{l}20 \text{ tons, or } 44800 \text{ (strength of plate)} \times 2 \text{ (two} \\ \text{sides of boiler)} \times \cdot 5 \text{ (thickness of plate)}\end{array}\right\}}{83 \text{ (diameter in inches)}}$$

$= \frac{44800}{83} = 539$lb. (pressure per square inch to [illegible]
solid plate) and 539 multiplied by ·7[illegible]
joint = 377·31b. (strength of joints), [illegible]
strength of boiler shell longitud[illegible]
weakest direction. Again, this [illegible]
get safe working pre[illegible]
would divide by 8, [illegible]
ance companies by 4, [illegible]
land b[illegible]
sure [illegible]
safe [illegible]
one [illegible]
ma[illegible]

must be reduced 10 to 20 per cent., as 94¼lb. would be allowed in case boiler was new, well constructed, and of reliable brand, as all makers brand good plates: "Best," "Best Best," or "Best Best Best," according to quality. Particulars of furnace tubes are too vague to make reliable calculations from; but supposing they are not strengthened at the seams, the collapsing pressure would be about 140lb., much weaker than shell we have been calculating, as 140lb. collapsing power must again be divided by 4 to get a safe working pressure, which would only be 35lb. for a tube 24ft. long by 2ft. 10¾in. diameter, made from ⅜in. plate, when it naturally follows that 35lb. is the strength (or safe working pressure) of the whole boiler, unless the furnace tubes are in some way strengthened. The strength of end plates can only be calculated after being either seen or minutely described on sketch, showing mode of staying. I have written so much recently on horse-power of boilers, that I feel almost ashamed to waste more time or valuable space in giving what I have repeatedly shown to be worthless, and now refer "Young Engineman" to "E. M.," August 31st, page 608, also several other numbers of last volume. The book I recommended to "The North" is in plain figures, with examples worked out in each case. It is published by S. Nicholls, Yorkshire-street, Blackpool, price 7s. 6d., and is a really good book, to be had only of the author, who I may here remark is an old correspondent to this paper. Should "Young Engineman" require further information on boiler queries or the above book, I shall be glad to correspond if he will advertise his address, as often a lot of valuable space is taken up for the interest of two or three only.—Boswell.

[51921.]—**Model Steamer.**—If you are intending to make a good working model, I should advise you to build your hull out of zinc strips, say No. 11 gauge and 1in. wide on wire ribs about 3in. apart, which are fastened to a wrought-iron keel. The details as to the arranging of the ribs and laying on the plates I could not very well explain without giving sketches which would take up too much room in "ours" if given all in one week. If you think a detailed description of my own 5ft. model would give you what you require, I shall be pleased to send it to "ours" for the benefit of all. My experience is, Don't have a wooden hull, as this soon warps and cracks with the heat.—S. Austel.

[51930.]—**Teazles.**—There are, or used to be, several fields of teazles grown in the neighbourhood of Polegate, Berwick, and Eastbourne, in the county of Sussex, and came to great perfection; but it is ten years since my last visit to that neighbourhood.—Ruby d'Or.

[51932.]—**Parasites on Bees.**—Unite weak one at once to next one to it, and spray all with dilute salicylic acid; also feed with syrup containing saltspoonful of acid to 5lb. of sugar and 1 quart of water. Spray combs in each hive and bees as well. J. I. S.

[51934.]—**Legal.**—To "W. T."—I am of opinion that the Married Woman's Property Act, 1883, does not apply to the case in question, as it relates only to questions arising since the 1st January, 1883. I presume the husband referred to was husband of M., as the wording of the query is vague. He died in January 1883, and M. would be entitled to the legacy in the ordinary course.—G. Russell Pridham.

[51938.]—**Musical.**—There is no actual reason why modern professors of music differ in naming the interval C to G flat. This, like other intervals, has different terms applied to it by different writers on harmony, some naming it an "imperfect fifth," others a "false fifth." The general name for it is a "diminished fifth." A fourth is dissonant except when an inverted fifth, that is, in the chord 6-4, and even then, according to Sir F. Ouseley, it should, in nine cases out of ten, be treated as a dissonance.—W. A. T., Dundalk.

[51940.]—**Waterwheel.**—The querist does not say whether the wheel is under or overshot, and does not give any particulars of the quantity of water available. These are required before an answer can be given.—Labor Omnia Vincit.

[51941.] — **Compound Locos.** — The high-pressure gearing is Joy's.—Vulcan.

[51941.]—**L. & N.W. Engines—Joy's Valve Gear.**—The compound locomotives on the London and North Western Railway *are* fitted with Joy's valve-gear. The two high-pressure outside cylinders have the valves placed below; but the inside [illegible] cylinder has the valve upon the top. [illegible] will again examine one of [illegible] the gear is of [illegible] positions.

acidulated with sulphuric acid, the wire will be instantly covered with copper, which will not rub off. Steel goods, such as scissors, &c., can be covered with copper by rubbing them with a rag wet with this solution.—R. A. R. Bennett.

[51944.]—**Coppered Wire.**—Iron and steel can be made to look copper-coloured by dipping the articles of of these materials into a solution of copperas. Copperas can be bought at any oilshop. You can also electro-deposit the copper on the goods; but I presume from the wording of your query that this process would be too complicated. —S. Austel.

[51945.]—**Boiler.**—By well-known formulæ both boilers would stand the same pressures; but I should say the less the number of riveted joints, the less the possibility of danger through joints giving way.—Engineer, Dewsbury.

[51945.]—**Boiler.**—Supposing the boilers were identical in every respect excepting the number of shell rings, I consider that the boiler with eight rings preferable to the boiler with eleven.—Labor Omnia Vincit.

[51945.]—**Boiler.**—Practically, the boilers are of the same strength. The chances are that the boiler with the eleven plates will give out first if tested with the other one to destruction. Everything in your case would depend on how they were set in the brickwork, and how they were used.—S. Austel.

[51947.]—**Link Motion.**—In "Allan's Link Motion," for reversing and for effecting variable expansion, both the expansion link and the valve rod are shifted by one movement of the reversing shaft in opposite directions—one upwards, the other downwards. By this means reversing may be effected with only half the vertical range of movement necessary when the movement is applied to only one of the pieces. In this case, the link is straight, and, therefore, the gearing is called "straight link motion."—Vulcan.

[51948.]—**Sanders-Bolitho Vacuum Brake.**—"To Physis."—The Great Western and Midland Railway Companies use the Sanders-Bolitho vacuum brake with modifications, or as more generally known, "*the two-minute brake.*" It has been fully described in back numbers, to which I refer your correspondent. The Midland or Clayton cylinder was illustrated, Vol. XXXII. p. 591. The steam brake on engine and tender, Vol. XXXIII. p. 68. The ejector, Vol. XXXIV. p. 548. The Midland or Clayton hose-coupling, Vol. XXXV. p. 265, and the Great Western pattern of brake cylinder, Vol. XXXV. p. 312. The defects in the system and details of failures will also be found in the same volumes.—Clement E. Stretton.

[51949.]—**Zoophyte Trough.**—Use marine glue. Heat the glass before applying. Recipes for marine glue I have seen in back numbers of the "E. M." It can be bought at any microscope shop.—S. Austel.

[51954.]—**Cement for Indiarubber Slips.**—Solutions of rubber or guttapercha, marine glue, or an ammoniacal solution of shellac.—Nun. Dor.

[51956.]—**Incandescent Lighting.**—I am not prepared to say that the EMF does remain the same. There is a good deal of misunderstanding about this matter, which is not altogether one of mere formulæ. I think that the current generated in a dynamo, even if separately excited, is modified by the external conditions to extent varying according to whether the limit of power is approached. The current in the armature modifies the polar state of the field magnets, and so the EMF produced; also, the total resistance has different relations to the external, as the number of lights is varied and the same current does not pass through, say, 3 lamps as would be passing when another circuit of 3 others is open.—Sigma.

[51957.]—**Weak Magnets.**—To "Sigma."—The weakness of the magnets is the cause of deficient action. The best way to strengthen them will be to take them apart, make a coil of wire which will slide freely over one of them, and pass a strong current in the direction to produce the proper magnetism. If you make a coil of about an inch in length and the same in thickness of No. 16 wire, and use either a Grove or 2 or 3 Smee cells, you will find how and when the desired strength is attained. The magnets should have an armature on when not in use. They ought to carry, at all events, twice their own weight. The strength might be got up by hanging weights on them singly and increasing the weight by degrees, and then using them to magnetise each other by the process of rubbing; but it would be a long job.—Sigma.

[51958.]—**Electro-Plating.**—The cause of the trouble is the not having sufficient free cyanide in the solution. Probably, also, you use anodes which are not pure silver.—Sigma.

[illegible]61.]—**Electric Testing.**—The description [illegible] confused: but it appears to indicate that [illegible] cells are wound with fine wires and the battery has not power enough to send so much current as is necessary to overcome the armature spring. At all events, the resistance is too great for the battery power.—Sigma.

[51962.] — **Water Company's Charges.**—Water rates are always payable in advance. "O." does not say when the water was cut off, and I suspect the water company were within their powers. As your correspondent is a householder, it should be a lesson to him to do his share in electing members to Parliament who will attend to their duties. As it is, the only way to compete with the water companies is to reduce the assessment for rates and pay more per pound, or to obtain a competing supply.—T. K. L.

[51963.]—**Electrical.**—With a small bichromate you might deflagrate a short piece of very fine platinum wire; but such cell would not last long whatever battery he uses, it is too small.—Watt.

[51963.]—**Electrical.**—A good battery for you. Get a glass jar and a porous jar to match; have ready, for a half-pint jar, about ¼lb. of bichromate of potash, take a leaden colander and hang on glass jar, so that when jar is half filled with water, colander is about a quarter covered, then put in ¼lb. of bichromate and pour on sulphuric acid to the extent of ½lb., which will dissolve the bichromate. Pour slowly, and stop when the liquid boils up. Put in the porous pot one part of sulphuric acid in eight of water. Two carbons go in the bichromate solution, and one zinc in the acid solution. The zinc should be well amalgamated. The carbons must be placed close to, without touching, the porous pot. A couple of thick rubber bands around each carbon, and one around both carbons holding them tight, to the porous pot, are useful. When not using the battery for (say) ten hours, the zincs and porous pots must be taken out. This battery can be used for lamps or motors. —C. R. Heap.

[51965.]— **Rash.** —Bathe the part night and morning for half an hour with soft soap and hot water, and afterwards apply the following ointment—viz., sulphur, ¼oz.; borax, 1oz.; vaseline, 4oz.; beeswax, ½oz.—The Kent Hermit.

[51966.]—**Making Small Drills.**—One way is to make the drill so that it does not go through the hole in the screwplate, but goes in the size larger easy. For example, making one for No. 10 it must not go through No. 10, but go through No. 9.—Watt.

[51972.]—**Valuation.**—You can work the sum thus:—Annual rent, less outgoings (taxes, repairs, insurance), multiplied by 12. Probable value £1,100; but depends on terms, state of repair, situation, &c.—R. Hannen.

[51972.] — **Valuation.** — Nineteen years' term from Jan. 1, 1884. Rent, £100 yearly. Query, value?

At 3 per cent. = 14·3 y.p. nett.
„ 4 „ = 13·1 „
„ 5 „ = 12·1 „
„ 6 „ = 11·2 „

Deduct 25 per cent. for all outgoings, and multiply residue by, say, 14, 13, or 12 y.p. as rate prefixed of interest. Or, say—

100 = [if nett, of course no deduction for
less 25 empties, repairs, collection, &c.]
—
75
12 y.p.
——
£900 as fair price.

(See "Investor's Tables" (2d.) to be had at 70, Lincoln's Inn-fields.)—X.

[51975.]—**L. & N. W. R. Locos.**—To "Vulcan."—In my query I asked when 148, 1012, &c., were rebuilt, not when they were built. I also asked who designed the class to which 1012 belongs only. No. 1012, 1074, 1075, 1056, and 1057 are of exactly the same class, and are stationed at Birmingham. 1012 was built in Feb. '62. The class to which 304 belongs was built from '66 to '73, by Ramsbottom; the "Lady of the Lake" class from '59 to '65, by Ramsbottom: and the large and small Bloomer classes, to which 1005 (Achilles) and 980 (Vandal), respectively, belong, from '51 to '62, by McConnel. The class to which 1888 belongs was built from '47 to '53; the date of 1888 being Sept. '47; and the class to which 148 (Penguin) belongs, by Trevithick, from '53 to '58. If interesting to any reader, I will give dimensions, stations, &c., of any engine of the above, or other classes of L. and N. W. engines; though I do not know in what year Mr. Trevithick's, McConnel's, or Ramsbottom's engines were rebuilt.—J. E. Spencer, Birmingham.

[51976.]—**Piano Wrest Plank.**—The best thing you can do is buy a set of pins. Leave the old pins in the plank, and bore the holes for the new pins ½in. above and ½in. below the crack. See that the pins fit very tight in the holes. Do one by one—i.e., put a new pin in, then uncoil the wire from the old pin and put it on the new one, pull it up in unison with the wire still left on the same note, then put that one on in the same way. This is the cheapest and most effective way to repair your piano.—J. H. Schucht.

[51977.]—**Defective Ejector.**—An ejector to work properly must have at the end of the suction pipe a very fine copper strainer, say, the holes no bigger than the eighth of an inch, and plenty of them. The discharge pipe to the sea must be straight from the ejector for, say, a foot, and then a bend, if necessary, to go through the hull. There must be no sharp angles either in the suction or the discharge. Now, in your case examine the suction and see if there are any bits of coal or coke in it by ramming a stout wire down. See if the entrance to the discharge pipe is chamfered off as well as the inside of the ejector at that part. Arrange for the discharge to come straight away from the ejector, and then carry it out above the level of the sea if possible. Of course you have a full-way cock to prevent the return of the sea.—S. Austel.

[51978.]—**Hyposulphate of Soda.**—By the term "hyposulphate of soda," I presume this querist means hyposulphite of soda, now more correctly called sodium thiosulphate. This salt can be prepared from common washing soda by saturating a strong solution of it with SO_2, and digesting the solution of sodium sulphite thus formed with flowers of sulphur for a few days, filtering, and crystallising. The SO_2 can be made by heating together charcoal and H_2SO_4, or from the combustion of sulphur or pyrites; when prepared by the action of charcoal on H_2SO_4, it is contaminated with CO_2; but this does not interfere with the above process.—W. E. Haden.

[51982.] — **Electro - Magnetic Machine.** — "A. C." will get very little from his machine if he makes it, certainly not enough to produce an electric light. "A. C." had better wait a little and read the papers by Mr. S. R. Bottone on the "Dynamo" now appearing in these pages.—Watt.

[51984.]—**Dissolving Guttapercha.**—Guttapercha is insoluble in "spirits." The solvents are bisulphide of carbon, mineral naphtha, oil of turpentine, benzol, and chloroform; but the last two are expensive and the first two those most commonly used.—Nun. Dor.

[51986.]—**Electric Currents in Dynamos.**—No effect can be greater than its cause; therefore, the polarity in the armature must be weaker than in the field; it cannot reverse, but does weaken and displace the field poles. As to my book, it is getting on, and 400 pages printed off; I suppose the printers will have it out of hand soon.—Sigma.

[51988.]—**Tapering Corks.**—There is no way of using a lathe for tapering corks. I make a machine specially for that purpose, and should be glad to give "C. W. F." information if he sends me his address. I advertise mine in this number. —J. Lowman.

[51991.]—**Astronomical.**—In reply to "Stella," I find that according to the star catalogue published in the "Encyclopædia Britannica," 8th ed., and confirmed by this year's *Whitaker*, α Andromedæ, α Coronæ, and α Ophiuchi are each of 2nd magnitude; γ Ursæ Majoris is mag. 2-3 (*Whitaker* 2), δ Ursæ Majoris 3-4 (*Whitaker* 3). Webb makes α Capricorni a wide double, giving α^1 as 4th. mag. and α^2 as 3rd. In Hubbard's *Directory*, 1882, I find amongst other publications, more or less astronomical (but none exclusively so), the following issued in Paris:—*Journal du Ciel*, issued twice a week; *La Nature* (illustrated) weekly; *Bulletin des Sciences Mathematiques et Astronomiques*, monthly. The prices are not given.—Arthur Mee.

[51993.]—**Engine Query.**—Undoubtedly your engine has either too much lead on steam side, or too small an amount of cushioning for such a speed. Close exhaust at about one-eighth of stroke if possible.—Engineer, Dewsbury.

[51994.]—**The Heliostat.**—I am afraid "M. T." will not find the instruments now being described sufficient for his purpose. Foucault's "Siderostat" is the instrument generally used in connection with a fixed telescope. The principle is exactly the same as that of the Heliostat, except (1) that the mirror must be a true plane, and silvered on the front; (2) the clock should be one with a conical pendulum, or the image will be unsteady; (3) means must be provided either with long cords acting on endless screws or long rods, to enable the observer to set the instrument while at the eye-end of the telescope; and (4) the whole construction of the instrument must be as faultless as the skill of a good optician can render it. "M. T." will find a description of the siderostat with an engraving on p. 290 of Captain Abney's "Photography."—A. T. Hare.

[51995.]—**Extracting Dust and Lime from Wool.**—A shaker, such as the Yorkshire shoddy makers use for dusting new cloth cuttings, would suit. You can buy them for hand or steam. I can show him a steam one, or I will give name of makers if you advertise your address.—R. A. J.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list and send what information they can for the benefit of their fellow contributors.

Since our last, W. J. Grey has replied to 51242, 51249, 51251, 51290; W. E. Haden, 51251; "Codadad," 51398; R. Hannen, 51543.

QUERIES.

[51997.]—**Induction Coil.**—Would Mr. W. J. Lancaster kindly answer the following queries?—(1) I am making an induction coil. When finished it will measure 6in. between inside faces of reel-ends and 3¾in. diameter. For primary, two layers No. 16 silk-covered copper wire soaked in paraffin. A cylinder is formed over primary with beeswax and resin—1 to 4 resin (common)—then two thicknesses of first quality printing paper, demy white 24lb., which is thickly coated with shellac varnish. For secondary, 13 layers of No. 36 silk-covered wire. Insulation for do.: After a layer of wire is wound on it is coated with shellac varnish to the depth of double the thickness of a leaf of the "E. M.," or perhaps rather more. Four thicknesses of the printing paper (soaked in paraffin) are then carefully and tightly wrapped round. Then another coat of varnish (like one before), then layer wire, coat of varnish, paraffin paper, varnish, &c., till all the wire is on, when eight layers or thicknesses of paraffin paper will be put on and coated with varnish (shellac). What is the greatest number of one pint and also half-pint bichromate of potash cells above coil will stand with the larger of the two condensers mentioned below? (2) I propose to have foils for condenser 7in. by 6in. If I had them 5¼ by 4in. (half area) would I have to double number of cells to get same length of secondary spark? (3) Is paraffin paper (as above) a good insulator for condenser plates? Is it better than varnished paper (same quality in both being used)? (4) Finally, what is the maximum length of spark that I may expect from the secondary of such a coil, by using maximum battery power, when condenser is fitted to coil and complete?—A Recent Subscriber in Australia.

[51998.]—**Brass Whistle.**—Will some of our musical friends favour me with the fingering of the brass whistle seen in most of the windows of the vendors of musical instruments. They are constructed and holed the same as the tin whistle, but are much better finished, and in the hands of a professional yield excellent music? Full scale required with various fingerings.—Flute.

[51999.]—**Steel - facing Copper Plates.**—Will some of ours inform me how copper plates are steel-faced and the chemicals used, and oblige?—Brass.

[52000.]—**Dynamo.**—Will "Sigma," S. R. Bottone, J. Sutcliffe, or any kind reader, assist me with the following?—I am making a small dynamo. The armature is 2¼in. long, 2in. in diam., composed of 14 iron plates, having 8 coils, wound with No. 20 wire, each coil containing 9ft. I want to know what number wire, and quantity, will be required for the field-magnets, which are cast iron, having two coils each, part of magnet to receive coils 1½ long by 1¾ wide by 5 1-16 thick? Also how many lamps it would light?—Spark.

[52001.]—**Wheel Grease.**—Can "Engineer, Dewsbury," or other of your numerous correspondents, give me a recipe for wheel grease suitable to use on a spur and pinion wheels, both iron, and running at a good speed? The usual heat of engine-room is 100° F., and upwards.—Simplex.

[52002.]—**New Inman Steamer.**—Can any one give the size of engines and any other leading dimensions of the new steamer *City of Chicago*? Also builder's name.—Simplex.

[52003.]—**Defective Coil in Galvanic Battery.**—The following are the instructions for the connections: Battery to screw C and Z handles to screw No. 1 and 2. Should this power be found too weak, remove the handle to screw 3 and 4. Different degrees of power may be obtained by connecting the handles to any pair of screws; but the strongest power is when the extreme screws are employed. Would any kind reader inform me how to make a coil? Also the quality and quantity of wire to be used, and what would be the more suitable battery for the same?—J. D.

[52004.]—**Silk for Flour Dressing.**—Having an order for a silk, seven sheets in length, and only being a country joiner, I am rather at a loss as to what the probable cost of making one would be (time only), having all material found me by the party it is for? Also, would like a sketch if any of ours could oblige me.—Amateur Millwright.

[52005.]—**To Mr. Allen.**—Will Mr. Allen kindly describe the kind of apparatus that is required (and is at present in use) for the determination of the albuminoids in milk, in which use is made of a funnel and cooler?—A would-be Fat Extractor.

[52006.]—**To Mr. Lancaster.**—Ellerbeck remarks—"Length of camera should be 50 per cent. more than the length of plate, although cameras as a rule are seldom more than 25 per cent." Kindly explain exact meaning of this. What I want to get at is exact utmost length required for bellows of ½-plate camera?—Alpha.

[52007.]—**To Mr. Wetherfield.**—A sick and death society, registered under the Friendly Societies Act, 1875, some twenty years ago made some investments in freehold property. The original loans, with accumulated interest, amounted to more than its value; consequently, the property was thrown on the hands of the trustees, who have since been receiving the rents, but no separate accounts are given on balance sheets showing what is being received for rent, or what is being paid for repairs, rates, &c., but simply stating in a lump sum what is received as interest on the whole of the society's investments. Are the trustees justified under the Friendly Societies Act in holding property fifteen or twenty years, to the detriment of the society?—Bilston.

[52008.]—**Poor Rates.**—I build a house of four rooms similar to adjoining houses, having the same frontage—viz., 20ft. When the rate collector first calls he rates me like my neighbours—at £12—but verbally says he will make it 10s. more next half-year. When the next half year's rate comes it is at £15, which I refuse to pay, when others are only rated at £12. The only satisfaction I can get from the collector is the house is better built—not a jerry house. What I wish to know is if I can be compelled, only on these grounds, to pay the increased rate, and my best course to pursue?—T. T.

[52009.]—**Improving Draught of Chimney.**—Would the exhaust of an engine led into a chimney stalk improve the draught and not injure the brickwork?—T. B.

[52010.]—**Lifting Water.**—I have an unlimited supply of water with about 5ft. fall, and want to lift about say 3,000 gallons 80ft. high per day. Could you tell me what power turbine I require, and what quantity of water will it require to work it, which water, I suppose, runs to waste?—Richmond.

[52011.]—**Wads.**—Could I get the sheets of luff, which the soft wads which are put between the powder and shot in cartridges, are made out of, cheaper than buying the wads cut out?—and what composition are they made of?—F.

[52012.]—**Bicycles at Night.**—Can any reader enlighten me as to the law regarding bicycle riding at night? The other night, not having my lamps on, I carried a flaming torch in my hand, and was stopped and thrown off by a man (not a policeman). Was he justified in so doing? Could the law touch me in any way, were he to summon me, either for carrying a torch or for riding "without a light"? Must a lamp, if used, be fastened to the machine?—G. Newman.

[52013.]—**Bees.**—I shall be much obliged if some of the readers of the "E. M." kindly answer the following—viz. (1) Is it a fact that foul brood is such a terribly fatal disease among bees, as stated in the "Modern Beekeeper"?—if, so, I am surprised it does not destroy nearly all the bees in the country, where the cottager, generally leaves his skep to take care of itself as best it can, and never dreams of salicylic acid being in the world at all. When it breaks out in a hive, we are told we can distinguish it by the rotting grubs in the cells. I ask, can it be known by any other signs? Has the hive a bad smell, or can it be distinguished any other way?—and in hives which have no brood, and which takes the disease from an infected one; how can I discern it?—(most hives have little or no brood now). Is it likely to come on at this time of the year, and what time is it most general? When it sets in in a hive, is it likely to destroy it, if left to itself? If some of the many readers of the "E. M.," who must have much experience of this sadly destructive disease, would give some information about it and its cure, also an occasional letter on the modern arrangement of bees, it would be a great boon to many beginners. (2) Is flour cake better than barley sugar, or sugar cake, for winter feeding? (3) When I take out the bars for the winter, is there any fear of honey and pollen souring in the cells (surely not if sealed), having unfortunately got no extractor on account of its high price? (4) What's the difference between Woodbury frame hive and the Abbott frame hive?—J.

[52014.] — **Sawmill Waste.**—Can any of our readers inform me what is the most profitable way of utilising saw mill waste? I have a quantity of pieces of ash, beech, elm, and oak, some of which would run from 12 to 20in. long, and square from 1½in. to 2½in. It seems wilful waste to have to burn all of it.—Sawyer.

[52015.]—**Photometers.**—To Rev. T. E. Espin.—Will the Rev. T. E. Espin kindly oblige the writer with a full sketch of telescope showing precisely where the stops, prism, and light are placed?—also give the inside diameter of hole in stop for a 2¼in. object-glass, give a drawing of prism, give its position in instrument? Of what use is the prism? I have absolutely wasted several hours every day, ever since it appeared, in trying to find out the use of the prism. I know it ought to reflect, but if it is in the telescope or not makes no difference. I placed it behind the large stop, midway between the object-glass and small stop; I use for a prism a piece off a chandelier drop, about 1in. long—is that the right thing? Give also the size of hole in matchbox? When the light just peeps over the bottom of object-glass, will not the matchbox stop off a greater portion of the object-glass?—Eta Orionis.

[52016.]—**Depositing Platinum.**—I am desirous of depositing the above metal in a reguline state upon copper foil. Will some practical correspondent kindly give me the method of making a solution, and the battery power required?—also the temperature at which the solution should be used?—E. T. M.

[52017.]—**Heating Water.**—It is proposed to heat water by steam for bathing purposes in a cylindrical tank, a coil passing through the centre; it could not be brought into the house, it is 20 yards from the boiler. The water when heated has to go to about 40 yards at each side of it—that is to the extreme ends of the building. The water is highly charged with lime, and consequently will block up the pipes in a short time. Would it not be better to run the steam all the way to both ends of building and heat the water there in open tanks? I should be very thankful if any of your readers would give me wrinkles of the advantages and disadvantages of the above.—Bernard.

[52018.]—**Portable Engine—one Cylinder.**—Will some kind experienced hand inform a new subscriber, and a young hand, how to reverse his engine to make the fly-wheel run the reverse way? I understand by shifting the eccentric, it is done; but I want to find out the proper and perfect way to do it. The eccentric is now keyed on, and there is no mark on shaft where to fix it for reversing. Also explain full particulars, giving lead to engine, what is meant by it and how to do it?—New Subscriber.

[52019.]—**Gas-Engine.**—In a late number of "ours," 50108, May 11th, "R. A." gave some valuable figures relating to gas-engines, and the distribution of the heat generated in the cylinders of the better class of silent engines. The figures relating to the waste of heat from the water-jacket seemed to me to be so astonishing, that I venture respectfully to ask "R. A." if he will favour us with his authority for the figures he uses, and if he will look over the answer he gave "Carbon," and confirm it?—W. Ainsworth.

[52020.]—**Right of Entrance**—In order to reach my backyard door, I have to enter a large gateway past two people's doors, and then go up a long passage, therefore never use it, but always use the front. I have been told that after a certain time I shall lose the right to use it at all; is this correct, and how long would it have to be closed? We have the place on a lease, if that makes any difference.—W. D.

[52021.]—**Raising Lid of Iron Box.**—I am constructing for a lady a strong wrought-iron box, the lid of which will be too heavy (about 2cwt.) for her to lift. Can anyone suggest to me a simple plan by which the lid can be easily raised and lowered? It must be so arranged that it will remain stationary at any height; and its own weight not cause it to come down with a rush. I should like sketches if possible.—Vulcan.

[52022.]—**Light Waves.**—It appears to me that light waves must have altitude as well as length; and that there must be a forward motion, as well as rocking from side to side as described in textbooks, or else how can light travel? Will some kind reader inform me whether both the altitude and the length of waves are known?—and if so, what they are, for, say, red.—No. Sig.

[52023.]—**Apprentice's Overtime**—To Mr. Wetherfield or "Lex."—I am an apprentice at the office of a newspaper, where we have a daily task set us, and as soon as we have finished that task, it has been our usual custom to leave work; but now the foreman says that my master could compel us to work overtime after that task is finished. Myself and the rest of the apprentices in the office have refused to work the overtime, on account of the money they pay us being insufficient. What I want to know could they compel us to work overtime after our task is finished?—A Comp.

[52024.]—**Recovery of Sulphur.**—Can any readers give me any information as to the recovery of sulphur from spent oxide from the manufacture of coal gas, by means of carbon sulphuret? A brief but concise description of the plant necessary for the operation would oblige.—A. S.

[52025.]—**Afterludes.**—As the organist of a large chapel, I am requested at the conclusion of the hymns, chants, &c., to play what (I believe) is termed an "afterlude." As my extemporising capabilities are somewhat limited, I should be glad if any reader could recommend a book or books, containing something after the style of Smart's preludes and interludes, but more varied.—Gamba.

[52026.]—**American Clocks.**—Of two small American spring clocks, the one goes tolerably well, although the regulator has to be set rather more frequently than is agreeable; the other runs always too fast, and, when lengthening the balance-spring, it stops very soon. I have sent it two or three times to a clock doctor, who charges invariably 2s. 6d.; but does not cure the evil. Could any of your correspondents say how it can be put right? The clock seems to have sufficient vitality in its power spring, and I don't see the reason why it could not be made to run approximately right. Cheap clocks are expensive.—Dux.

[52027.]—**American Egg-Boilers**—I have bought successively two American egg-boilers with sandglass and balance weight, which tip over and sound a small bell, when the sand of the upper part has filled the lower part. The sand sometimes stops running and the eggs get uneatable. Why does the sand stop running, and how can it be cured?—Dux.

[52028.]—**Wimshurst's Induction Mac** [illegible] Will any of "ours" kindly inform me h[illegible] the above machine is made?—how are the [illegible] revolve so near one another and in opposit[illegible] wish to have particular directions as to [illegible] glass discs to the axle.—Exo.

[52029.]—**Ebonite.**—I have a[illegible] electrical machine, and accidentall[illegible] too near the fire, by which it beca[illegible] to flatten it by placing between [illegible] Can any of "ours" lead me ou[illegible] give me instructions how to flatte[illegible] that its diameter is 18in.—Exo.

[52030.]—**Photographi**[illegible] room for dry-plate work, [illegible] window to open into the o[illegible] by 11in., opening into another room. Have glazed this with deep ruby; but now find in consequence of the window getting no direct light, that it would be quite impossible to see to develop a negative—in fact I cannot see my own hand unless held up to the glass. Under these circumstances, will it be best to procure deep yellow, orange, or pale ruby glass? I do not wish to use a lamp if it can be avoided. The plates I propose to use are Edwards' extra sensitive. Also, how long will hypo. solution for fixing keep, and can it be used more than once?—Ruby.

[52031.]—**Dynamo.**—I have fitted up a dynamo, and wish to ask for a little advice from "Sigma," "S. Bottone," "W. P. A.," and others. The amature H section, soft cast iron, is 10in. long, 2¼in. diam., and is wound with No. 18 double c.c. wire. I varnished the iron first of all with shellac varnish, then put round a strip of glazed brown paper and varnished that, and then wound on the wire tightly and varnished over all. By calculation (from rules obtained from last Vols. of "ours" and Sprague's "Electricity") the R of armature is ·5 ohm. The c.i. F. M.'s are wound with same kind of wire, in a similar way, and the R is 3 ohms. There is no leakage. The commutator is a brass cylinder split diagonally, one part driven on spindle, the other insulated from it on ebonite bush; the halves of commutator are insulated from each other by vulcanised fibre 1-64in. thick. Wire from armature coil secured on commutator by a screw. Brushes, of copper wire, are arranged to swivel round commutator so as to get best position. Clearance between A. and F.M.'s, 3-32in. With a Leclanché cell in circuit, and a galvanometer connected to the brushes, I get a deflection of 90°. On taking the cell away, and running armature at 3,000 revs., I get a deflection of 15° Will some one kindly point out where I have gone wrong? I made the galvanometer according to S. Bottone's directions. The brushes are insulated from each other, and the galvanometer shows the change of current when the cell is connected to terminals, and armature turned slowly. Are the F. M.'s not sufficiently magnetised?—Labor Omnia Vincit.

[52032.]—**Leather Stains.**—I have a pair of rollers covered with leather, through which I pass certain goods in a damp state, and have latterly been bothered with the tanning from the leather staining the goods. Can I extract the tanning by immersing the roller in any liquid compound, or by any means whatever? Shall be pleased to have the opinion of "ours" on the subject.—Bothered Again.

[52033.]—**C.R.**—Wanted chief dimensions of the new C.R. locos of Mr. Drummond's designs?—J. E. Spencer.

[52034.]—**G.N.R.**—Wanted particulars of the small single-wheel engines 101A and 102A, also of 644, 678, 30, and 598.—J. E. Spencer.

[52035.]—**Copying Tracings.**—In copying tracings by Willis's aniline process it is necessary to vaporise the aniline colours. Can any correspondent tell me how this is managed? I have tried dissolving the aniline crystals in methylated spirit, and heating by a spirit lamp; but the spirit appears to evaporate and leave the aniline all in the dish. What is the proper method of procedure? I may add I coat the paper with bichromate solution as follows: Water 1oz., bichromate ½drachm, phosphoric acid (B.P.) 3 drachm. Is this a proper proportion of acid, &c.?—Ditton.

[52036.]—**Street Medical Coil.**—Will Mr. Lancaster, "Sigma," or some other electrician, kindly say if it is best to build up the coil on the bundle of wires forming the core? If so, how am I to get the brass tube to slide over same when the secondary is wound on, after the manner of a coil described in "E. M.," No. 469, 1874, as I cannot clearly understand how it is done from the description there given?—Electric.

[52037.]—**Freehold Property and Building Societies.**—A man dies, not having made a will, leaving a widow and an only son (a minor). Amongst other is a freehold property mortgaged to a building society, part of the amount advanced having been repaid in the usual way. After the lapse of about four years (the son being still under 21) the administratrix, who is the widow, wishes to pay off the balance on the said property, but the society say there is no one to whom they can legally give a release until the son attains his majority. I want to know if this is correct. If not, could you kindly quote a precedent, and greatly oblige?—A Minor.

[52038.]—**Boiler.**—Will any reader tell me which is best? I have at present two boilers working with 70lb. with reducing valves on. Would it save coal if I took the reducing valves off and work the boilers at 30lb.?—H. P.

[52039.]—**Scagliola?**—In the new "school of art" here I observe a number of columns—square and round—presenting the appearance of, say, highly-polished porphyry; but on examination they are found to consist of of a cast-iron tube covered with this material. How is this put on, and how is such a high polish attained?—A., Liverpool.

[52040.]—**Apprentices and Housework.**—Would "Lex," or any legal correspondent, answer the following?—Can a master legally compel an apprentice to do his housework, and is an apprentice obliged to obey his (the master's) wife's commands? If he is not, what means (legal) could he use to get out of doing it?—E. H. Gutteridge.

[illegible] **Dynamo Electric Machine.** [illegible] me to make my machine [illegible] structed it from instruc- [illegible] Feby. 7, 1879, also [illegible] this time. The [illegible] divisions, having [illegible] m wire in each [illegible] way, and [illegible] cted [illegible] 'e to [illegible] of [illegible] fect; then I put the current through all the machine, and this gave good results; then I tried the inner poles with a compass and found two norths facing one another and two souths. On running the machine at from 1,000 to 2,000 revs. per min. only got a very weak current. Can any reader inform me where my mistake is? If any one will, I shall feel greatly obliged.—Williams.

[52042.]—**Faulty Telescope.**—I should be glad if any of your able readers versed in telescopic matters could set me right on the following: Mine is a 3in. o.g. of two lenses, one a double convex and the other a plano or, at any rate, as near as I can tell, a plano-concave. It might be convexo-concave, but I think it is plano-concave. Whichever is outward, the following phenomenon happens: When high power e.p. is used (say 250 diam.) on first mag. star I get a good disc, but round it are some peculiar rings, alternately light yellow and dark chocolate. They are perfectly circular, and don't agree with me, I can tell you. With lower powered e.p. it is the same, but not so marked.—R. I. N. G. S.

[52043.]—**Limelight for the Lantern.**—I want to make a simple and yet effective apparatus for communicating a slow rotary motion to the limes used in lantern oxy-hydrogen limelight. The clockwork arrangement sold by opticians is beyond my purse, and the bevel wheels or coil used (in lieu of this) troublesome. Can Mr. Lancaster, or any of "ours," suggest how one with a fair amount of mechanical skill could make such an apparatus?—A sketch would greatly oblige.—Iota.

[52044.]—**Induction Coil.**—Will any of ours tell me the length and diameter of core, also size of wire, and number of layers for primary most suitable for a coil where the secondary consists of about 11oz. of No. 36 silk-cov. wire? What length spark ought it to give with one pint bichromate?—L. W. Willis.

[52045.]—**Checks upon Tramway Fares.**—Can any of "ours" describe the check upon fares adopted by the different tramway and omnibus companies, both English and foreign, and oblige?—Lletram.

[52046.]—**Midland Express Engine.**—Will some kind reader give me details of a fine new express engine just turned out (last week), No. 1602, also Nos. 1603 and 1604, which have been turned out to-day?—Historian.

[52047.]—**Midland Ry. Engine.**—Will "Meteor" oblige with details and numbers of 10 very powerful shunting engines lately built? Also what traffic the little engines Nos. 1322, 3, 4, 5, 6 are intended for?—Historian.

[52048.]—**Oxychloride Mercury.**—Wanted very badly a simple test for the purity of this preparation. I am told that a pure sample should completely volatilise over a Bunsen burner, and that any residue would be an adulterant. I get a considerable residue from my consignments. Will our analysts, with their usual kindness, please assist by saying if this test may be relied on?—R. W. J.

[52049.]—**Railway Gate Hinge.**—Can some correspondent kindly give sketch and dimensions suitable for a railway crossing gate 20ft. long? Also for occupation gate 10ft. length?—Railroad.

[52050.]—**Rolling Stock.**—Wanted some information as to dimensions, tires, &c., of different sorts of passenger and goods rolling stock in America and Canada; sketches will oblige.—Railroad.

[52051.]—**N.B.R. Locomotives.**—Could any friend oblige by giving dimensions of the N.B.R. Co.'s, four coupled bogie express locos.? They take the Midland Scotch expresses between Edinburgh and Carlisle.—N. B. R.

[52052.]—**Spectrum, Temperature of.**—I want to show the difference of temperature in the different bands of a spectrum, thrown by a limelight through a bisulphide of carbon prism, on to a screen about 8ft. from nozzle of lantern. Would the best way be to use a thermo-electric pile and galvanometer multipler bearing a small reflector to magnify deflection? If so, what would be the best form of thermopile?—and also the best size of wire for coil of galvanometer?—L. U.

[52053.]—**Valve Spindles.**—Will someone kindly favour me with instructions how to prevent indiarubber sticking to valve spindles? I intend using a piece of tube made of fine rubber for packing—will it do?—Elela-Rath-Vera.

[52054.]—**Flute.**—"Vulcanite" or "Old Blowhard" would much oblige by the method used to find the proper places on a flute of any given length and bore. (1) For distance from top to aperture for blowing. (2) The distances of the other holes from said blowhole, and the length of pipe to be left below the lowest hole. Also the usual diameter of bore at present considered best, and whether cylindrical or taper, and what form of tool is best for cylindrical, and what for taper boring, with any hints for finishing smoothly, &c.?—Constant Reader.

[52055.]—**L. and Y. Locos.**—Would some correspondent kindly give principal dimensions of the above company's bogie engines, as 669? Also of tanks like 111?—Vulcan.

[51056.]—**To "Sigma."**—I have an acquaintance who has been confined to bed for about five months. His right foot and knee are very much swollen. If the knee gets any less the foot will get as much thicker, and *vice versa*. A medical man has been attending him during this time, and the only treatment has been to paint it with iodine, which seems to do no good whatever. As an amateur mesmerist, I should like to try the effect of mesmerism upon it, but never having mesmerised any one in bed before, or for any complaint, I should like some advice in the matter. It has been my intention to draw it from the knee to the foot and outwards at the toe end.—Student.

[52057.]—**Imitation Glass.**—There is a method of treating pasteboard advertisements to give them the appearance of having a glass front. I think gelatine is the substance used. I have tried gelatine alone, and also one part gelatine to four parts glycerine; but have failed. I should feel very grateful if anyone would tell me what is the real substance used, and how applied?—Advertiser.

[52058.]—**Liquids Immiscible with Oil.**—Would any reader of ours kindly name any liquids heavier than water, which would not mix with oil? (mercury excepted).—Conical Plug.

[52059.]—**Telephonic.**—Can any of our readers inform me concerning the new telephonic transmitter alluded to in the *Standard* of Oct. 16th, which will transmit both loud and soft sounds?—also the following details concerning the Blake transmitter? (1) Of what material and thickness should the diaphragm be? (2) What form of carbon answers best? (3) What quantities and sizes of wire should be used in the induction coil? (4) Will two No. 2 Leclanché cells be a suitable battery for a short circuit (20 ohms)?—St. Barto.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* Editor *of the* English Mechanic, 31, *Tavistock-street, Covent Garden, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

Pattern Making.—It may interest "Orderic Vital" (letter 21912) and others to know that we have in preparation a series of papers by the author of "Pattern Making," which anticipate all that "O. V." asks for. Further articles on cognate subjects will also appear by the same author.

The following are the initials, &c., of letters to hand up to Wednesday evening, Oct. 17, and unacknowledged elsewhere:—

J. T. Chapman.—McCowen and Heald.—F. C. Farrow.—Jones Bros.—D. Fraser.—A. S. Gladstone.—J. D. Morrison.—P. J. Davies.—J. E. A.—Bow.—H. N.—G. W. W.—J. P., Stafford.—Boswell.—P. M.—Cork Wood.—L. M. B.—W. H. C.—J. Johnson.—Pressure.—P. A. D.—L. S.—Arthur R. Hallett.—Pantograph.—Cyclist.—F. Wetherfield.—S. Austel.—A Fellow of the Royal Astronomical Society.—Meteor.—T. G. Elger.

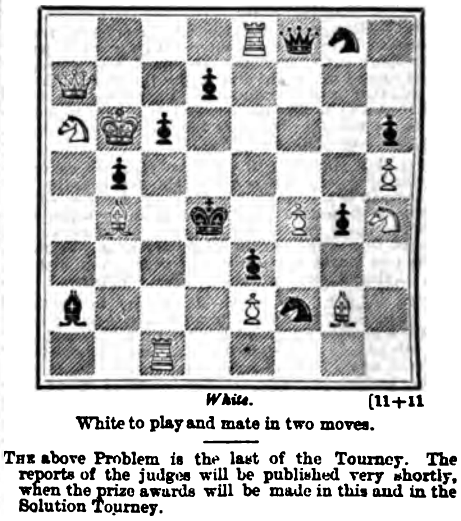
Combustion. (It depends upon the conditions in which it is burned. Twelve times the weight of coal is the short answer; but if a chimney stack is used as a draught producer, about twice that quantity. See pp. 329, 338, 360, 458, Vol. XXXV.)—Alif. (The process has been described many times in back numbers, but "full instructions" means so much, that we doubt whether you will find them anywhere. See pp. 74, 125, Vol. XXVII., and the indices since. You will find one process described on p. 580 of the last volume.)—Luminous. (You will find a recipe in No. 739, p. 256; but you can buy it cheaper than you can make it on a small scale.)—E. J. A. B. (Refer to p. 5, No. 859, for the principle of one, and p. 326, No. 763, for illustrated description of Cowper's writing telegraph.)—F. B. (Look through the indices. It is impossible to answer such a question without giving a list of alloys. Perhaps you will find something to suit on p. 134, last week.)—Belto. (We must refer you to back numbers. They are usually made of pieces of zinc and copper. There is a description of a good one in No. 301, p. 348.) G. R. K. (See the indices of the last seven volumes, or p. 95, No. 914.)—Nemo. (We have given several electric engines in recent volumes. Perhaps you might find one to suit you.)—Workman. (You do not say "foreman" of what; but presuming you mean of mechanics, you will find Templeton's "Workshop Companion," Lockwood and Co., and Molesworth's Pocket-book, E. and F. N. Spon, useful.)—Jaquis. (You should have looked through back numbers. We cannot afford space for working drawings of interest to only one or two correspondents, and in your case you can get what you want from Mr. Hallewell, of Hanover-street, Manchester.)—Another in a Fix. (Look up the subject in back numbers. You do not mention what is the composition of the solution, and yet expect somebody to guess what is the matter with it. Probably the best thing to do will be to recover the silver and make up a new bath. For methods of recovering, see p. 168, No. 917. In all probability, it is spoilt by the rosin.)—X. Y. Z. (You should have said how you "put it together," or, preferably, have referred to back numbers, where the construction is described very fully. It is briefly manganese and coke in a porous cell, and zinc outside, sal-ammoniac being the excitant. The order may be reversed.)—G. Fryer. (You do not appear to understand that the idea of using tubes is a very old one, although we have already called your attention to that fact on p. 98. If you will attempt to make an instrument with such tubes as you show in your drawings, you may possibly discover the reason why they are not adopted. You should look at the specifications at the Patent Office and consult our back volumes, or, which is perhaps the more crucial test, submit your notions to a practical man with a view to sharing in the profits.)—Nicaragua. (It is a Chiton, but of what species we do not know. We believe you will find a collection in the British Museum (Natural History), and a number of figures in L. Reeve's "*Conchologia Iconica.*")—A Puzzled Beginner. (Star charts and star maps are now within the reach of everybody; but if you look in Vol. X. you will find some articles that will help you. Possibly if you hold your map above your head and and study it in that position, you will cease to be puzzled.)—E. B. F. (You cannot make one unless you can produce an almost perfect vacuum. Your idea of corking a bottle after exhausting the air will never do. The motion is due to the action of radiant heat in causing rarefaction of the air near the surface of the vanes. Surely you remember that all the explanation possible has been given in back volumes—see index to Vol. XXIV.)—Ignoramus. (We believe there are some old-fashioned devices on the French coast, but we have no particulars. They are scarcely motors in the sense you mean.)—T. Edge. (Yes, we believe so; but under the circumstances you should consult an ophthalmic surgeon.)—W. Chapman. (If the articles are not so opaque that light cannot reach the glue, a little bichromate of potash added to ordinary glue will render it insoluble after the light has had time to act on it.)—J. F. Smith. (We have quoted the words of the Act, and can do no more. If the officials of the Patent Office will not act in the spirit, and, for that matter, according to the letter of the law, that is a question for patentees and the officials to settle between them. We know nothing of a fee of £8, and cannot understand why you should expect £7 to be refunded; but imagine that you will find the total fees are practically reduced, or section 45 is an absurdity. The fact is, it would puzzle the whole bench of judges to say what is really meant by the sub-section.)—W. Cahill. (1. No. 2. Can it, by any possibility, become inorganic?)—John S. Abbott. (You could try boiling a solution of caustic soda in it, or, if you do not mind running the risk of cracking it, you could heat it and plunge it while hot in a tub of water.)—Oudeis. (Clean with solution of washing soda, wet them with turpentine, and expose to the sun under glass. It is doubtful whether you will do much good with them. You will find several recipes in back volumes.)—Water Drinker. (Quite right; there are plenty in the market in which the filtering medium can be cleansed. See, however, p. 61.)—Per Mare. (Illustrated instructions on p. 618, No. 884.)—Butler. (No book published on the subject. There are several articles in back numbers, and several patent specifications.)—Elliot. (The *Electrical Review*, 22, Paternoster-row, would, perhaps, suit you best.)—J. F. (We suppose you mean No. 892; but surely you can look through the indices. 2. The best way to obtain a thorough knowledge is to read up the textbooks and practise the art.)—F. W. (Query answered many times. Coat with varnish, and when tacky, dust on bronze powder, or else paint with Bessemer paint.)—Pharmaceutical. (You do not explain what you mean by "chemist," and the signature suggests "druggist." You will find the question answered in both aspects in back numbers.)—N. C. (Would Mitchell's "Manual of Practical Assaying," Longmans, suit your purpose?)—A. S. (The query is indefinite—transferring what? You will find a number of recipes in back numbers.)—H. H. B. (You will find one answer on p. 462, No. 930, and several others by searching the indices. The best way in the case of small animals is to carefully bury them near an anthill or where scavenger beetles can get at them, bleaching the bones by exposure to the sun under glass.)—R. J. J. (You may find something to suit on p. 216, No. 841. The ordinary form contains a mainspring and escapement.)—B—M. (We believe the correspondent gave all available particulars, but there may be more in the *Lancet*. You have seen what Dr. Edmunds said about it.)—Correctness. (Unwin's "Elements of Machine Design" would be a suitable book, but Molesworth's Pocket-book would answer the question.)—Little Eaton. (It is a remarkable fact that such queries as yours always come from "total abstainers." A medical man must examine you, and find out if possible the cause of the symptoms you describe.)—Ham. (It depends on the cement. Try running spirit round the edge and gently prising with a knife. If that does not appear to dissolve the cement, try benzol or sulphuric ether.)—G. C. (Hoare's "Iron and Steel," 6s., Crosby Lockwood and Co., Stationers' Hall-court, E.C., is the book you require.)—A Young Mechanic. (We suppose you can use an old boot with a hole cut in it, and as the "hard substance" is not a corn or a bunion, you had better let a surgeon see it.)—A New Reader. (The best way to set about it is to hire an instrument and examine its construction. Directions for making the American organ were given in Vol. XXVI., and notes on harmonium construction throughout nearly the whole of the thirty-seven volumes completed.)—Les Dents. (Place them in a coil of wire, and pass a strong current through it.)—W. R. S. (No doubt you want a pair of suitable spectacles; but no one can give a useful opinion without examining the eyes.)—W. Brown. (We forget the publisher's address; but you can get the book of Mr. Calvert, Great Jackson-street, Manchester.)—F. A. F. (The fresh-cut surfaces of indiarubber will adhere if pressed tightly together; but the pouches are usually moulded and cured.)—A. Craig. (Without a specimen we cannot say; but oxalic acid will discharge most black inks.)—New Beginner. (Get a catalogue from Mr. Calvert, Great Jackson-street, Manchester, and see if you can find any books that are likely to be what you want.)—Ignoramus. (If the bubbles are blown by mixtures of coal-gas and air, or hydrogen and oxygen, they will explode when a light is applied.)—Moddler. (Use bleached wax for the first; but modeller's wax is made of equal parts of beeswax, lead plaster, olive oil, and yellow resin, with sufficient whiting. Colours can be added to suit. Vermilion, or any of the red pigments will answer your purpose.)—L. S. (The simplest would be a good red ink; but you could use one of the aniline colours.)—Gwalia. (You will find a number of formulæ in the "handbooks" and in back volumes; but the following keeps a long time, and is fit for use in twenty-four hours. Chloride of gold 1gr., acetate of soda 30gr., distilled water 5oz.)—Y—Cymro. (Carron oil or liniment of lime is made by shaking together equal parts of lime water and linseed oil. Use olive oil if you like. Make the lime water by slaking a piece of quicklime, and shaking it up well with water. Allow it to stand in a covered vessel, decant, and mix with the oil. Half a pound of quicklime is enough for six quarts of water.)—Bookcase. (Not too much if properly made.)—S. Boswell. (Anything that has not appeared, except a post card to hand this morning, has not reached us.)—T. E. Lingwood. (Nonsense, we have had to do it long ago on much less. You will find what you want in the advertisement pages of the *Daily Chronicle*, or any of the London local papers.)—W. H. L. (The registrar *can* claim a shilling if he calls at the house to register the birth. In one or two cases that we have met with, the registrar's "office hours" seem to have been so arranged that the above arrangement is in most cases a compulsory one. How far this is justifiable we do not know.)—J. D. D. (You had better patent it first.)—A Young Engineer. (We know of none; but a good series of articles on "Bridge Construction and Design," with plenty of illustrations, is now appearing in the *Building News*.)—E. D. Cooke. (You can sue the young lady in the County-court, but you will probably get laughed at for your pains.)—Perplexed. (It is not a question of law, but convenience. Better ask a respectable solicitor; he may perhaps himself suggest a trustee.)—A Mother. (Keep a light knitted cap on the baby's head, just reaching the tips of the ears.)—A. S. Williams. (Too late this week, and will be unfortunately valueless next.)—A., Liverpool, G. H. Lancaster, Scotus, L. O. Vincit, Salvo Jure, and others. (In type.)

CHESS

All Communications for this department must be addressed to J. Pierce, Bryn Rhedyn, Llandwrog, Carnarvon.

PROBLEM DCCCLVII.—R. I. P.

Black.



White. [11+11

White to play and mate in two moves.

The above Problem is the last of the Tourney. The reports of the judges will be published very shortly, when the prize awards will be made in this and in the Solution Tourney.

Solution to 855.

White.	*Black.*
1. Kt-K 4	1. P takes Kt (*a*)
2. Q-R 4	2. K takes B or P moves
3. Q mates	
	(*a*) 1. P takes B (Q) (*b*)
2. Kt-Kt 3 (ch)	2. K moves
3. Q mates	
	(*b*) 1. P takes B (Kt) (*c*)
2. Kt-B 2	2. K moves
3. Q mates	
	(*c*) 1. K takes B
2. Q-Q 4 (ch)	2. Anything
3. Mates	

NOTICES TO CORRESPONDENTS.

Correct Solutions to 853 by F. P. P.; to 854 by D. Mackay, F. P. P., Dicky Sam; to 856 by R. A. Bennett, Dicky Sam, C. Planck (a charming and accurate little puzzle), J. B. of Boxford.

S. Seymour Follwell.—Your solution to 855 is not correct: if 1. $\frac{\qquad}{\text{P-Q 7}}$ 2. $\frac{\text{Q-K R 4}}{\text{P-Q 8 (Kt) (ch)}}$.

H. Vivian.—Thanks for game.

Mac.—In 849 if 1. $\frac{\text{R-R 4 (ch)}}{\text{B covers}}$, Kt can't move to Q Kt 6 mating, as W K would be in check. We were not aware that the works in question were out of print. You would probably find the help you want in Miss Beechey's "Chess Blossoms" recently published. The price, we believe, is 2/6; the authoress's address, 16, Prince of Wales-terrace, Dublin. We are always glad to see attempted solutions, even if incorrect.

W. Anderson.—It is impossible to mate if 1. Kt-K B 3; but see solution above.

English Mechanic Tourney game between Mr. Jowett (*White*) and Mr. Clothier (*Black*):—

The English Mechanic
AND WORLD OF SCIENCE AND ART.
FRIDAY, OCTOBER 26, 1883.

THE FUTURE OF THE TELEPHONE.

IT cannot be doubted that the action of those holding the telephone patents in this country and in the United States has done much to check invention; but there are signs that before very long such companies as hold control of existing patents will be ready enough to adopt any really useful improvement, instead of buying it up and practically burking it. Mr. Preece, at the recent meeting of the British Association, in the course of a paper on telegraphic intercommunication, described the telephonic system adopted by the Post Office, which has been brought to so great a degree of perfection that London telephone subscribers, who are debarred from its advantages, envy their provincial brethren who are fortunate enough to have the Post Office telephone system at their service. Mr. Preece expressed the opinion that when attacks as to the validity of the patents ceased and things settled down, the companies, finding the Post Office had a better system, would adopt it; but with a touch of irony he explained that the Post Office switch board would probably not be used, for the simple reason that it is not patented. Whatever may be the ultimate fate of the telephone companies, it is quite certain that they do not satisfy Londoners, the majority of whom would willingly see the whole telephone exchange system handed over to the monopoly of the Post Office. For the sake of progress in connection with the telephone, one might hope that neither the Post Office nor a company will be able much longer to practically crush invention, for as we have pointed out before, the inventions of Reis show that no one now living can claim to have discovered the principle on which the telephone acts. On p. 542 of the last volume we gave an account of the decision of the examiner of "interferences" in the United States, which introduced an opportunity for long-continued litigation between Bell and McDonough, and the decision in our courts, though not quite so sweeping or confusing, it will be remembered, still leaves the monopoly of the receiver practically to Bell. Whether that monopoly will be broken down by the best of all means—other inventions—remains to be proved; but there are at least a few coming forward, which in the event of a less sweeping judgment in the appeal cases now pending in America, may have a chance of being developed in time into public favourites. For instance, Prof. Dolbear has invented what he calls the static telephone, which is not much affected by induction or bad weather. The instrument is tolerably well known; but it formed the subject of a discussion at the late meeting of the American Association. The instrument consists of a ring of ebonite, within which are two metal plates, parallel to each other, and separated by a body of air, a non-conductor. The line carrying the current is connected to one plate, and the other is caused to vibrate, when what may be considered the enlarged terminal of the wire is electrified. This system dispenses with magnetism and a return circuit (the body
the equivalent); but it re-
electromotive force, and
There
transmitter and sounds can still be heard across a room. Instruments that have been used for some time work better than new ones. Whatever may be said by special pleaders, and those who have to administer the law, there are few scientists who will not agree with Prof. H. A. Rowland, that such an instrument as Dolbear's static telephone is entirely different in principle to the magnetic telephone. When the plates are charged one hears better, and the explanation is the same as that which applies to the Thomson electro-meter, which is more sensitive when the jar is charged, in consequence of the attraction then being proportionate to the square of the difference of potential, instead of only the simple difference. Prof. Dolbear says that the instrument is a most delicate electro-meter, and when fully charged and in good working order one can apply the instrument to his ear, and hear himself speak, even when the two plates are connected with each other through the induction coil. Trials made with this telephone on a line between Boston and New York show that it is scarcely, if at all, affected by bad weather for insulation, and that, probably in consequence of the high electromotive force, any induction from neighbouring telegraph lines is very slight, and does not interfere with work. It will be seen from this brief account that the static telephone is deserving of more attention than it has yet received, for it seems especially well adapted for work in such crowded towns as London.

Another new telephonic system is that of Mr. A. F. St. George, by means of which the inventor claims that messages can be transmitted long distances, with very little interference from inductive action, and with much ease in working. The transmitter in this system consists of a disc of carbonised wood (or other suitable organic matter), which is resonant and capable of conducting electricity. This disc is supported in a frame having an aperture to direct sound-waves on to one face, while behind it hangs by a fine metallic wire a ball of very hard carbon. This ball touches lightly against the disc, and when the latter is vibrated by sound-waves, the former makes little excursions over the disc, thus bringing fresh points of contact into use. The connections are made in the usual manner with a battery and the primary wire of an induction coil. So far, there is nothing very novel in the arrangement, nor in the receiving instrument, which consists of two or more discs of mica, arranged parallel with each other in close order, and mounted at their edges in such a way that they are free to vibrate. One side of each disc is coated with metal, preferably silver, and it is advantageous to perforate the discs at the centre. The discs are arranged with their metal faces looking in one direction, and are connected alternately with each other, one set being attached to one wire of the circuit, and the other set to the other wire. This condenser arrangement is believed to increase the audible effects produced by the receiver. The remarkable feature of Mr. St. George's invention is the recording receiver, which is intended to reproduce at any distance and at any time, the sounds originally transmitted to it. We do not know whether any experiments have been made with this receiver or not; but as the newspapers have had paragraphs about it, and several correspondents have inquired as to the truth of the statements made, we give the following description:—The novel apparatus consists of a flat transparent disc of glass, which revolves at a uniform speed. One surface of this disc is coated with a
lm sensitive to the action of the light
ordinarily known and used in photogra-
processes," and the whole arrangement
ed in a dark chamber. An aperture
is provided, through which a beam of light can pass and fall upon the surface of the sensitised plate in any desired position, and the aperture is so arranged in connection with the sensitised plate that a beam of light is made to trace a spiral line on the surface of the latter. This spiral line will, so it is said, vary in width in exact proportion with the character and strength of the vibrations of the telephonic diaphragm. The sensitised plate is developed and fixed in the usual way, and is then ready to reproduce the message at any time. That is done, or is said to be capable of being done, by passing a beam of light through the glass plate to a selenium receiver, by means of which undulations are produced in an electric current and reproduced as audible sounds in a telephone receiver. By some means or other the newspapers have been persuaded to publish a note of this invention; but it may be doubted whether any really successful experiments have been made with the apparatus, though it is not impossible that in the future something of the kind may be utilised; but we are afraid it is not the direction in which to look for that improvement in the telephone service which is so much needed.

There are other improvements which await only a favourable opportunity for introduction; but at present the "opportunity" of the inventor is confined to offering his instruments to the Post Office authorities, and experience teaches that that is not at all a wise thing to do. Nevertheless, it must be confessed that the department having decided on adopting the system has completely beaten the companies who, by permission, supply a telephonic service to Londoners; but at the same time the present aspect of affairs is crushing invention, and that in a direction which promises to become very fruitful, if only a possibility of adequate reward can be observed in the distance. Something depends on the result of the cases now awaiting decision in the United States, for besides the appeal of Bell against the decision which gives McDonough the patent for a receiver combining a magnet and a diaphragm, there is Drawbaugh's case, which reopens the whole subject. Unfortunately, these cases drag out to such a length that there is a probability of the patents running out before the final and irrevocable decision is given. All of which tends, as we have endeavoured to show, to discourage invention in a direction in which just now it is most needed.

HOW TO MAKE A CHEAP LATHE.—I.*

The Patterns.

IN this and successive papers I purpose giving such information upon the above subject that any one moderately skilful in the use of engineer's tools, as I presume most of the readers of the ENGLISH MECHANIC are, shall be able to construct a serviceable lathe capable of doing wood or metal work at pleasure. It will be very nearly, though not quite in every detail, a description of one in my own possession which I made several years since. I wanted a lathe for general wood turning chiefly, but capable of being adapted for plain metalwork also, and I did not want either to spend a lot of money or to make too protracted a job of it. Possessors of Holtzapffel's lathes and members of the Amateur Mechanical Society would, perhaps, scarcely bestow more than a glance upon it. But for the majority of English Mechanics, those who, like myself, gain their living in the pursuit of a trade, high prices are prohibitory, and a tool that will do rough woodwork as well as light metal turning is the most useful.

---

* The writer of these articles desires to say, for the information of "Orderic Vital" (letter 21912), and possibly of others also, that the outline of the present subject was sketched, and the earlier papers written, before the letter of "O. V." appeared. Without, however, departing from his original intention of describing a "cheap lathe," the writer will throw into a supplementary chapter the special information relative to the gap bed, which "O. V." desires.

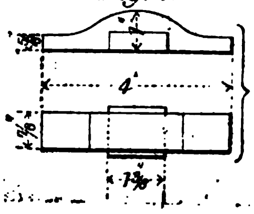

Fig. 8.

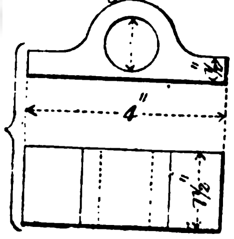

Fig. 9.

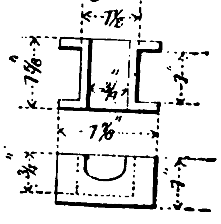

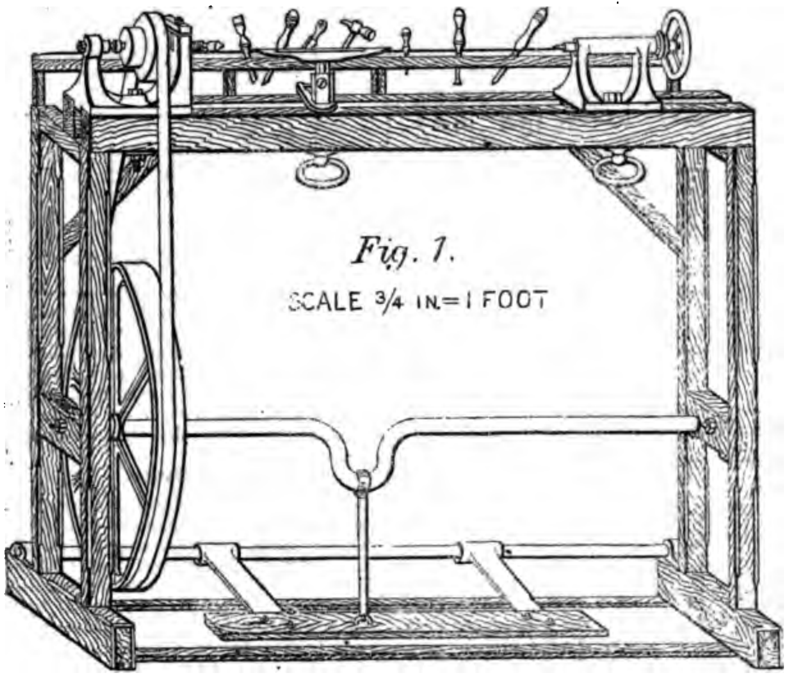

Every one, moreover, of a mechanical turn likes to possess a lathe, and a fairly substantial article is like a good microscope stand—once procured, an almost unlimited number of accessories can be added subsequently. In describing this, my lathe, I write for the benefit of my fellow craftsmen, and of apprentice youths, who often possess more ambition and ingenuity than loose cash, rather than for those wealthy amateurs to whom the outlay of a few pounds, more or less, is of little consequence. It possesses strength, lightness of motion, fair capacity, being neither a toy on the one hand, nor unwieldy on the other, and is alike suitable for wood or metal work. It is suited to the requirements of the wood turner, the pattern maker, the amateur electrician, and student of mechanics who wishes to construct his own apparatus and models, as well as for home amusement, the making of fancy articles, furniture, repairs, and so forth.

It has wood standards and a wooden bed. The poppets—5in. centres—are of cast iron. The headstock has a wooden rigger to receive a strap, and the mandrel runs in parallel brass bearings—not so good, of course, as conical steel bushed bearings, but good enough for ordinary work, and much easier for the amateur to fit up. The movable poppet carries a hollow mandrel, traversed by an internal screw (the neatest method), and the dead centre is removable at pleasure, to allow of a drill plate being slipped over the mandrel nose. The driving wheel is of cast iron, and the crank is of wrought iron throughout, casehardened at the ends, where it runs on steel centres. The bed is 4ft. long and stands 3ft. 3in. high. There is a T wood-turning, and a slide rest, besides various chucks. Fig. 1 gives a correct representation of the appearance of the lathe, as well as of the relative proportions of its parts, being drawn to a uniform scale.

We assume that our patterns are to be home made, in which case they will cost little or nothing, the material required being so small that almost any odds and ends of stuff can be rendered available. Fig. 2 represents the headstock; Fig. 3, the poppet. Both headstock and poppet will be jointed longitudinally, not because that is the only way to make them, but because it is as good as any other in the present instance.

For the headstock, then, get out two pieces for the foot, finished to 7in. by 2⅜in. by 1in., and dowell them together by corresponding edges. Also two pieces for the front of the headstock 4¾in. by 2in. by ⅞in.; connect with one dowell, and cut out the curved portions *a a*, to relieve the heavy appearance which would be produced by the upper portion (enlarged for the reception of the screws of the cap) being continued straight down to the base. Prepare two pieces for the hinder portion of the headstock. 5¼in. by. 2in. by 1in., connect with one dowel and cut curve and boss as drawn. Rebate the foot to a distance from each end equal to the thicknesses of the front and back, and to an ⅛in. below its face. Screw front and back into their respective rebated recesses, being assured that they stand at right angles with the base. Into the inner angles glue square blocks *b*, *b*, indicated by dotted lines, and when dry strike out and work 2in. radii with gouge and round plane. The boss for the back centre will be thickened up with two thin facings *c*, *c*, turned and sawn in half with a dovetail saw and fastened one on each face.

The facings for the mandrel bearing will be prepared, four pieces 1½in. by 1in. by ⅜in., and fastened in position. Two prints, also in halves, requiring four pieces 1⅛in. by 1⅛in. by ⅛in. bradded upon the facings. The boss for the tightening bolt *d*, and the guidepieces *e*, each in halves, will complete the pattern, save that the sharp edges should be taken off all round the upper portions to a $\frac{3}{16}$in. radius, to aid in giving a graceful outline to the casting. The corebox F is made to the dimensions over the prints. No hole should be cast for the tightening screw, nor for the reception of the back centre.

We will make the poppet, Fig. 3, similarly. It is as often, however, made without the longitudinal joint, the barrel being turned solid and jointed loosely to the ends. Two pieces for the base, 6in. by 2⅜in. by ⅜in.; two for each end, 4in. by 2in. by ⅜in., cut out to radii given, the barrel turned in halves to figured dimensions and notched to fit on the ends. Boss for tightening bolt and also for set-screw will be required for this pattern. Work the hollows *b b* as in the headstock, fasten on the guide pieces, and round the edges as before. In making these patterns, it is better to give a shade of taper in the direction of their draw, just a couple of shavings, say, thinner on the down side than on that next the joint, to aid in their withdrawal from the sand. This, which is very important in patterns having a deep lift, is often neglected, however, in these smaller ones, the rapping alone usually being sufficient to insure easy delivery.

For the rest, prepare the base to dimensions given (Fig. 4), cutting out the slot in the pattern to deliver itself. Turn the socket with a long print on the end, and secure to the base with a stud. Put on the boss for the tightening screw loosely with a wire *a*. For the T-piece, prepare a piece of stuff 10in. by 1½in. by ½in., and work to shape, half-sized sections being given at middle and ends A A, the shank being turned and fastened to this.

The hand wheel, Fig. 5, can be cut out of a solid piece of hard wood, exactly like the casting, to dimensions given.

In reference to the driving wheel, it will be advisable, first of all, to have a look into the secondhand dealers' shops for the chance of picking one up, with possibly a crank attached. Then if the quest fails, proceed with a pattern—in this case made flat for a belt rather than grooved, a grooved pulley involving perhaps more metal turning than many amateurs could accomplish with the appliances and tools at their disposal. Make it thus (Fig. 6):—

Build and glue up three courses of segments out of, we will say, the four of which the rim is to be composed. Full instructions for building up the rims of wheels are given in the "E. M.," Vol. XXXVII. p. 143. When built up, turn their inside diameter to finished size. Leaving the partly-made rim for awhile, plane up three strips of stuff 1ft. 11in. by 2¼in. by ⅝in. for the arms, and lock them together in the manner described on page 191 of Vol. XXXVII. On these pieces so locked together, mark out the six arms to dimensions given, leaving the portions which are to be let into the rim the 2¼in. wide to include the radii. Now, returning to the rim, recess it in six places to dimensions corresponding with those at the ends of the arms, and drop the latter into the spaces thus prepared. Lastly, over the ends glue up the last course of segments and complete the turning of the wheel.

This assumes the use of a lathe large enough to take 23in. diam., and as many persons might not be able to obtain the loan of one so large in capacity, it is well to mention that the wheel can be made well enough without a lathe at all, by striking the circular portions with trammels, and cutting carefully with paring gouge and chisel, as is sometimes done at a push, even in workshops, if the engine happens to be stopped, or all the lathes are preoccupied.

Turn two bosses 2¼in. diam. by 1¼in. thick and fasten them, one on each side of the wheel arm, putting a 1in. core print on the centre of one of them; round the edges of the arms, and put on double ribs to give rigidity and elegance of appearance.

There will be a cap for the headstock to dimensions, Fig. 7, having facings corresponding with those on the headstock; also a couple of small castings, as Fig. 8, for the treadle bar. We shall want also a pattern for the brasses, Fig. 9. For this, cut a bit of wood 1½in. by 1in. by ⅝in., also two thin pieces 1⅜in. by 1in. by $\frac{1}{16}$in. Brad these latter on the first piece as indicated, and cut out the bearing to ⅝in.

Not to be bothered with too many matters of detail at one time, and being, moreover, anxious to see some of our metalwork under way, we will get these, the chief parts, cast at once, and give our attention to chucks, slide-rest, and minor matters afterwards.

Now what about expense? The headstock and poppet will together weigh 30lb., the flywheel 70, and the rest, with the other castings, 10lb.; total, 110lb. From 12s. to 14s. per cwt., according to locality, is a fair price for this class of work, so that 15s. at the most will tide us thus far, reckoning 1s. for the two brass bearings, about a pound in weight.

ASTRONOMICAL NOTES FOR NOVEMBER, 1883.

The method of finding the Sidereal Time at Mean Noon at any other Station will be found on p. 373 of Vol. XXXVI. The Zodiacal Light may still be looked for in the East before sunrise during the earlier part of the month. Watch should as usual be kept for spots, faculæ, &c., on every day when the sun is visible.

The Moon

Enters her First Quarter 4·4 minutes after midnight on November 7th, and is Full at 4h. 37·3m. p.m. on the 14th. She will enter her Last Quarter at 1h. 43·6m. in the afternoon of the 21st, and be New at 6·h. 54·2m. p.m. on the

Occultations of (and a near approach to) Fixed Stars by the Moon.

29th. Higher tides than usual may be looked for about the 14th and 15th.

Day of Month.	Moon's Age at Noon.	Souths.	
	Days.	h.	m.
1	1·5	0	52·4 p.m.
6	6·5	4	55·4 ,,
11	11·5	9	9·4 ,,
16	16·5	1	6·8 a.m.
21	21·5	5	41·9 ,,
26	26·5	9	19·7 ,,

The Moon will be in conjunction with Saturn at 5 p.m. on the 15th; with Jupiter at 7 p.m. on the 19th; with Mars at 6 p.m. on the 20th; and with Mercury at 10 p m. on the 29th.

Mercury

Is a morning Star (in the sense of Southing before Mean Noon) during the whole of November, but comes into Superior Conjunction with the Sun at 6 a.m. on the 26th. He may be probably be caught with the naked eye before sunrise during the first week of the month; but his approach to the Sun will render his detection dubious after this. His angular diameter decreases from 5·4″ on the 1st of November to 4·6″ by the 30th.

Mercury.

Day of Month.	Right Ascension.		Declination South.		Souths.	
	h.	m.	°	′	h.	m.
1	13	31·6	7	31·1	10	50·1 a·m.
6	14	1·3	10	44·3	11	0·0 ,,
11	14	31·9	13	53·6	11	10·9 ,,
16	15	3·2	16	49·1	11	22·5 ,,
21	15	35·1	19	25·1	11	34·6 ,,
26	16	7·6	21	37·5	11	47·4 ,,

It will be seen from the above Ephemeris that, starting from the constellation Virgo, Mercury will travel right across Libra, and will be found at the end of November in the South-Western part of Ophiuchus. His path lies through a region destitute of any conspicuous stars.

Venus

Is an Evening Star, but is most indifferently placed for the observer through the entire month, her increasing Easterly elongation from the Sun being quite nullified by her great and rapidly-increasing South Declination. Her angular diameter increases quite insensibly from 10″ to 10·4″ during November.

Venus.

Day of Month.	Right Ascension.		Declination South.		Souths.	
	h.	m.	°	′	h.	m.
1	15	8·6	17	20·5	0	26·8 p.m.
6	15	33·9	19	7·6	0	32·3 ,,
11	15	59·7	20	41·8	0	38·4 ,,
16	16	26·0	21	1·4	0	45·0 ,,
21	16	52·7	23	5·0	0	52·0 ,,
26	17	19·8	23	51·5	0	59·3 ,,

Venus's path this month commences in Libra, and after crossing that constellation and the Southern part of Ophiuchus, finishes where the last-named constellation and Sagittarius are conterminous. As we remarked above in connection with Mercury's very similar route, this lies in a part of the sky destitute of stars of any size.

Mars

Souths in the Early Morning during the entire month, but rising between 10 and 11 at night at the beginning, and soon after 9 p.m. at the end of it, may be fairly well seen after midnight. His angular diameter continues steadily to increase from 9·1″ on the 1st to 11·2″ by the 30th; and a sufficiently powerful telescope will now begin to show traces of markings on his disc. He is in Quadrature with the Sun at 7 a.m. on November 1st.

Day of Month.	Right Ascension.		Declination North.		Souths.	
	h.	m.	°	′	h.	m.
1	8	45·5	19	38·9	6	4·7 a.m.
6	8	54·4	19	12·1	5	54·0 ,,
11	9	2·7	18	46·6	5	42·6 ,,
16	9	10·4	18	22·8	5	30·6 ,,
21	9	17·5	18	1·4	5	18·0 ,,
26	9	23·8	17	42·9	5	4·7 ,,

The path indicated above carries Mars from Cancer into that absolutely blank part of the sky in the Western Confines of Leo.

Jupiter

Rises between 9 and 10 o'clock at Night at the beginning of November, and about 8 p.m. at the end of it. Hence he is coming into view during the later working hours. His angular diameter increases from 36·5″ on November 1st to 39·6″ by the 30th.

26	8	27·8	19	31·8	4	8·8 ,,

This short arc lies wholly to the W.S.W. of the Præsepe in Cancer.

Saturn

May now fairly be regarded as an Evening Star, inasmuch as he is above the horizon during the greater portion of the working hours of the night. The nearer, of course, to midnight he is observed the more favourably will he be placed for the observer. His angular diameter increases insensibly from 18·2″ to 18·4″ during the month: the opening of his rings being equally imperceptible. He will come into opposition to the Sun at 4 a.m. on the 29th.

Day of Month.	Right Ascension.		Declination North.		Souths.	
	h.	m.	°	′	h.	m.
1	4	29·6	19	47·1	1	49·5 a.m.

11	4	26·7	19	40·4	1	7·3 ,,
16	4	24·8	19	36·0	12	41·8 p.m.
21	4	23·1	19	32·3	12	20·5 ,,
26	4	21·4	19	28·6	11	59·1 ,,

The short arc thus indicated lies above Aldebaran, with which Star Saturn will be in conjunction at 5 a.m. on November 2nd at a distance of 3° 30′ North of it.

Uranus

Is still invisible.

Neptune

May be seen all night long, and coming as he does into Opposition to the Sun at 9 a.m. on November 12th, is in a very favourable position indeed for the Observer.

Day of Month.	Right Ascension.		Declination North.		Souths.		
	h.	m.	°	′	h.	m.	
1	3	12·1	15	59·4	12	28·3	p.m.

26	3	9·3	15	48·3	10	47·3	,,

So that Neptune will still be found in that void region of the sky to the S.E. of δ Arietis.

Shooting Stars.

The strange tale of the identification by Prof. Adams of the long-known meteoric shower of November 12—15th with the little Comet discovered by Tempel in 1866, has been so often told in these "Notes" that bare reference to it here will suffice. All, then, that will be necessary is to reiterate the caution that it is useless for the observer to begin his watch for this meteor stream until its radiant point to the North and West of γ Leonis appears above the horizon. This does not happen until about midnight, prior to which it is useless to look out. The Maximum display occurs on the Night of the 13th; but straggling members of the stream appear a night or two on each side of this date. Other displays from Andromeda, Perseus, and Ursa Major may be expected between the 24th and 28th: the night of the 27th being one on which the observer should be on the alert. Suspicions exist, too, of showers on the 19th and 30th.

Greenwich Mean Time of Southing of Fourteen of the Principal Fixed Stars on the Night of November 1st, 1883.

The Method of finding the Greenwich Mean **Time** of Southing of either of the Stars in the **above List** for any other night in November, will **be found** on p. 375 of Vol. XXXVI.; as will **also** the mode of determining the Local Instant **of its** Meridian Passage at any other Station. **It is** to be noted that the rules there given are not **rigidly** accurate when applied to Polaris or any **other** close circumpolar star; although they **will** doubtless prove sufficiently so for all practical purposes.

LIFE UNDER THE OCEAN WAVE.

UNDER this title Mr. P. H. Carpenter gave on Tuesday week the third of the series of Penny Science Lectures now being delivered at the Royal Victoria Coffee Hall, Waterloo-road, S.E. The chair was taken by the Rev. W. Copeland Bowie, who introduced the lecturer as the son of Dr. W. B. Carpenter, C.B., and brother of the gentleman who had addressed them on the two previous Tuesdays, Mr. W. J. Carpenter. The lecturer said he within the last five-and-twenty years, it was generally believed by scientists and zoologists, that a depth of 300 fathoms, or 1,800ft., was about the extreme depth at which any living organisms could exist beneath the sea, and that beyond this depth all was barren, owing to the great pressure of the water. It was recognised that near the shore the sea abounded with animal life; but the number of living organisms was supposed to rapidly diminish at about 200 fathoms, and from that to 300 fathoms to disappear. This belief was not, it was true, universal; but those holding a contrary opinion were but a small minority of scientific observers. Notwithstanding this generally received opinion, certain facts had been ascertained which tended to the supposition that it was wrong. So long ago as 1818, during Sir John Ross's Arctic explorations, living creatures had been brought up from depths of 1,000 to 1,200 fathoms in a perfectly fresh condition, and when people began to sound the ocean for the purpose of finding suitable beds in which to lay telegraphic cables, the prevalent belief was rudely shaken and had to be abandoned. The first proof of deep-sea animal life was given during the repair of the cable between Sardinia and Africa in 1860, so that telegraphic engineers, and not scientists, were the pioneers in this field of study. The Sardinian-African cable had to be taken up for repair in that year, and there were found on the broken pieces of cable many living organisms, some of which, from their rooted base and mature structure, had evidently been anchored to the line, and had lived on it for several years. In the year 1868, both on this and the other side of the Atlantic general interest was awakened in the problem of the conditions and character of deep-sea life, and commissions of inquiry and investigation were sent out by both the British and United States Governments. The result of these and subsequent expeditions has been that scientific observers have gradually come to the conclusion that the bottom of the sea differs as much in various parts as do similar tracts of land, that it teems in most places with animal life of the most varied kind; that there are mountains, valleys, and many undulations on the surface of its bed, covered by many different classes of soils, and that the ranges of climate are great, varying from moderately warm currents to others where the cold exceeds the freezing point in spring water, and that each of these varieties of depth, soil, and temperature is marked by its peculiar classes of organic life. He would now, with the aid of the oxyhydrogen light, turn over a few pages of the new book of submarine life which, though only revealed by these recent explorations, had been foreshadowed more than three centuries ago by the poet Spenser in one of the opening passages of an early book of "The Faërie Queene."

The lecturer then explained and illustrated the means by which deep-sea explorations were carried out. The vessel was provided with many miles of rope, marked so as to denote the distances payed out. This was coiled up along the side of the deck and was wound in after a sounding by means of a donkey engine. It was found better to drop the five or six half-hundred weights, by which the rope was loaded so soon as it touched the bottom, than to haul them up several thousand fathoms, and the manner in which the circular weights were detached from a clip by the slight shock of grounding was shown. The actual tools used were a dredge and trawl – the former in earlier expeditions was a tube provided with a leather valve opening upwards, so that the tube was open as it pierced the mud and was kept closed during the winding in. A later plan was to employ a gripping appliance, which seized a small portion of the mud and closed upon it, and this Bailey sounding apparatus, with detachable weights, was that used on the *Challenger*. Besides the dredge, there was a strong net, set on a strong iron frame and having attached to it by rods two swabs of frayed out oakum; the latter were frequently the most effective portion of the instrument, and even when the dredge, after being drawn along the bottom, came up empty, had numbers of specimens adhering to them. To prevent strain on the dredge or gripping appliance from the pitching of the ship, indiarubber accumulators were fastened to the upper end, and these yielded to the pressure; one of the sides of the dredges was also tied together with rope, so that if any great destruction were encountered in the drawing it up the rope would break and the dredge be saved. The lecturer proceeded to show on the screen enlarged pictures of the animals brought up by the tube and dredge. The most common find, both as skeletons and living examples, was an elementary organism about the size of a pin's head, consisting of a hard limestone porous base filled and covered with gelatinous substance, through which numerous sharp spicules protruded. The jelly-like substance, or protoplasm, exuded through pores in the central shell, and its arms as minute points, which were continually in movement died, their skeletons fell to the bed of the sea, and lay there closely compacted in masses resembling loose chalk. Indeed, it was found that similar structures constituted the bulk of our chalk deposits, and anyone who, remembering this, looked at the cliffs on our south-eastern coast could not fail to be impressed with the vast numbers of these minute creatures, which had gone to build them up, and this process was continually going on at the bottom of the ocean. These organisms had many varieties, differing chiefly in the arrangement of the spiny processes or arms. Some classes absorbed flinty and not limy particles from the water to build up their skeleton; many of these which had not projecting arms adhered to rocks and grew in large masses, the skeletons being familiar to all of us as sponges. One of the most beautiful examples of this class was the form called "Venus's flower-basket," originally found near the Phillippine Islands, but now known to exist in many parts.

Passing on to consider corals, the lecturer exhibited several varieties, and explained their method of growth and reproduction. Of starfishes there were a very large variety and number found in deep seas. They were symmetrically divided into five hollow rays, the centre containing a mouth on the underside opening into a capacious stomach; from apertures in the rays protruded a number of small tentacles, by which the animal moved and brought food to its mouth. A curious feature was that the young were carried, while immature, in cavities on the starfish's back. A variety frequently met with at great depths was the slenderly-formed brittle or sand starfish, and it was one of these animals, brought up in 1818 by Sir John Ross's expedition, which first set scientific men thinking that probably the deeper parts of the ocean were inhabited. Several other varieties, including the hair starfish, were shown, and the lecturer passed on to exhibit specimens of sea cucumbers, which he explained were closely allied to the well known and very abundant fossils familiarly termed sea lilies or encrinites. When mature they had annulated stems set with root-like processes, by which they fastened themselves to rocks, and a large head from which a fringe of tentacles protruded. In an immature state they swam about freely till they found a suitable anchorage. The extinct species were much larger than the modern ones; the annulated stems of some of those more numerous would, if they had remained unbroken, have been from 70 to 75ft. in length. The living species has a great range, and were found in 1867 by the *Porcupine* expedition in the Bay of Biscay and off the Norwegian coast, and had since been brought up from depths all over the bed of the Atlantic. In conclusion, Mr. Carpenter said he might be asked of what good was all this knowledge of the deep seas to the working man? It would not, he must admit, lower his baker's and butcher's bill, nor increase his power to earn money, but tended to increase our knowledge of the completeness and perfection with which the world has been made. The consideration of the wonderful way in which the deepest seas were teeming with beautiful and complex living organisms led our thoughts up from the book of nature to Nature's God.

Last Tuesday night a lecture was given by Mr. E. B. Knobel, hon. sec. of the Royal Astronomical Society, on "Comets."

HARTLEY'S DRY PLATE PROCESS.—

I.*

BEFORE giving a formula for making emulsion, I wish to state the theory upon which I base my formula, also several of the experiments I made which led me to adopt the same. Sensitiveness of a gelatine emulsion depends upon the fineness of the bromide of silver in the gelatine; the finer it is, the more rapid.

Weak solutions give finer precipitates than strong solutions. Acid solutions give finer precipitates than alkaline solutions.

Some have said that the sensitiveness of an emulsion depends upon its being more or less alkaline—the more alkaline, the more rapid—therefore they use ammonia to make it alkaline. Now, ammonia partially dissolves the bromide of silver, making it finer, therefore more rapid. It is not because it is alkaline. Anything that will dissolve the bromide of silver and not decompose the gelatine, whether it is acid or alkaline, will do the same thing. By boiling an emulsion the heat partially dissolves the bromide of silver. The more bromide that is used in excess of what it actually takes to precipitate the silver used, the less boiling it will take, because the excess of bromide will dissolve the bromide of silver, and the heat will hurry it along. The more acid an emulsion, the longer you can boil; the more

You all, no doubt, have made ammonia-nitrate of silver, by adding ammonia to a silver solution until the oxide of silver formed has redissolved. I tried this with bromide of silver, and I found by adding bromide of ammonium or bromide of potassium to a precipitate of bromide of silver, that the excess would redissolve the bromide of silver, making a clear solution, same as excess of ammonia redissolves the oxide of silver in making ammonio-nitrate of silver.

When the bromide of silver is all redissolved, it is in the finest possible state of division. I added this to the gelatine, which makes a clear, transparent mixture, and when I began to wash it, it began to emulsify. The longer I washed it the quicker it would work. I thought I had just the thing required; but on a trial I found that it was too rapid, and the plates would have to be made and handled in absolute darkness in order to work them successfully. Besides, the bromide of silver added to the gelatine in this state decomposed it, so that it was difficult to get it to set. I therefore got my fineness of bromide of silver by the same theory, but in a different way.

I also found by numerous experiments that the intensity of a negative depends upon the proportion of silver to the gelatine. The more silver, the less intensity and more detail. One half-grain of silver to each grain of gelatine will make a very intense negative, while two grains of silver to every grain of gelatine will make a very thin but full detail negative. When gelatine is boiled it refuses to set without a cooling slab, and when not heated above 140 to 150 degrees, and then only long enough to flow the plates, they set and dry without any trouble. I also find that it is not necessary to use the gelatine so thick as recommended in published formulas (namely 30 grains to the ounce), as it takes longer to set and dry, and is a waste of emulsion, as intensity can be regulated by the proportion of silver to the gelatine, and not by the thickness of the film. I also have proven, by repeated experiments, that a gelatine solution, when acid and in a jelly state, will hold 200 per cent. of silver, and when it is alkaline it will hold sometimes not more than one half-grain of silver to each grain of gelatine; this depends upon how alkaline the gelatine is. Mr. Driffield, on page 93 of *British Year Book*, 1883, states that gelatine in a jelly state will hold but a small amount of silver, and then only as a sponge holds water; that if you attempt to cut or squeeze it, the silver comes out in solution. This is only the case when the gelatine is alkaline and never when acid. Acid gelatine will hold 200 per cent. of silver, and can be cut or squeezed without danger of losing a drop of silver.

I also have proven that bromide of silver formed from alkaline solutions is not as fine as when formed from acid solutions; and that the weaker the solution of bromide, the finer the precipitates of bromide of silver.

Pure bromide of silver is not sensitive to light, but only becomes so when in combination with organic matter, such as gelatine gives to it. My formulas are based upon the above facts.

I will give my formula in detail, just as I proceed, step by step, in the making of the emulsion, and will afterwards describe the apparatus used.

Formula.

Take any hard gelatine—Swiss or Heinrich's—soak it for twelve hours in water, changing the water three times during the twelve hours. Do not cut it up. Take it out of the water and lay it on clean paper to dry. No matter how much of this you fix in this way, as when dry it will keep as before.

Take 75 grains of carbonate of soda (not bicarbonate) and 60 grains of citric acid, and put into three ounces of warm water in a quart pitcher; when the citric acid and carbonate of soda are dissolved and all effervescence ceases and carbonic acid gas has passed off, add 16 ounces cold water and 720 grains of the soaked and dried gelatine and let it stand thirty minutes; now dissolve 720 grains of silver (prepared according to formula given) in six ounces of water. Place the picher containing the gelatine in hot water—do not let the temperature exceed 110 degrees. When the gelatine is all dissolved, which will take about fifteen minutes, add the silver solution to the warm gelatine; rinse out the vessel you dissolve the silver in with two ounces of water, and add it to the gelatine solution; when the silver is added it will immediately turn white (if it turns brown the gelatine is not good, and must be discarded). Stir well. Now take a bowl large enough to hold the emulsion, wax it inside with beeswax, being careful not to leave an excess of wax; this is to keep the emulsion from sticking to the bowl. Pour the silvered gelatine into the bowl and set away in a temperature of 40 to 60 degrees to set. When this becomes a jelly, which will take about four hours, cut it into strips about one-fourth inch square, using a silver knife or horn spatula. Put strips of silver gelatine into a half-gallon [illegible] into the washing box (described [illegible]) solution through the pipe into the pitcher on to the gelatine:

Soda carbonate	150 grains.
Ammonium bromide..........	720 ,,
Alcohol	4 ounces.
Water (about 60 to 70 degrees)	12 ,,

Stir this every half-hour for two hours. When you stir it, take washing box into dark room, shut the door, and by red light only take off the cover; give it a good stirring with a glass rod and replace the cover. To tell when the silver is all formed into bromide of silver, take a small piece of the jelly to the light and cut it in two; if it is all alike, the action has taken place, if it is not the same colour all the way through, there is still free silver present. Do not put the piece back into the pitcher, as it would fog the balance. When the silver has all been formed into bromide of silver, the emulsion could be washed, melted, and plates prepared, but they would be slow. Now leave the emulsion standing in this brine of bromide of ammonium, &c., from one to five days or more, according to rapidity you want. Three days makes a rapid plate, five to six days makes a very rapid plate. The reason of this is the excess of bromide of ammonium partially dissolves the bromide of silver. The longer it remains in the brine, the finer it becomes; also, the weaker the brine, the finer the bromide of silver. But by making it weaker than is recommended here takes too long for the bromide of silver to form.

To Wash the Emulsion.

Let the water run through the tube to bottom of pitcher and off at faucet below. To tell when the emulsion is sufficiently washed, take some of the waste water running from the faucet into a two-ounce bottle and add a few drops of silver solution; there will be a precipitate of bromide of silver. In an hour take some more of the waste water, and add a few drops of silver solution, and if there is no precipitate of bromide of silver, the emulsion is washed enough. If there is still a precipitate of bromide of silver, continue to wash until, upon trial, there is no precipitate formed. Stirring the emulsion several times will hasten the washing. Never take off the cover to the washing box, except in red light after you add the brine.

The emulsion is now ready to be preserved for future use, or to be used at once.

To use at once, tie a piece of coarse canvas over a large bowl, pour the emulsion on to canvas and let it drain free of excess of water; put back into pitcher and place into hot water in apparatus described hereafter. Melt at a temperature of 140° to 150°. Add two ounces alcohol and two ounces pure albumen. (To prepare the albumen, beat the white of eggs to a stiff froth and set aside to go back to liquid.) Add two drops of a saturated solution of chrome alum in water to each ounce of emulsion: this is to keep the gelatine from frilling. There should be 35oz. of emulsion when finished; if not, make up with water. Make smaller quantities in proportion.

To Flow the Plates.

Filter the emulsion through a piece of moist flannel in the glass funnel, placed in the tin funnel as described hereafter; filter into a small pitcher that will hold about six ounces. You can have several of those small pitchers in hot water; as you empty one you can be filtering more while you use the others. The small pitchers are for flowing out. Have your plates cleaned as described hereafter, and have them about as warm as when you varnish. Hold the plate with the left hand, the long way towards you, pour some emulsion on the centre of plate, let run to the farther right-hand corner, then to farther left hand-corner, then to corner you have hold of, and off at the nearest right-hand corner; leave sufficient on the plate to make a rather opaque film. Practice will guide you in how thick to have them. If they come out too intense, you have too much on: if too thin you have not enough on. Move the emulsion on the plate until it is smooth, and then place upon screw-eyes as described hereafter. When you have six flowed, the first one will be ready to put upon a rack to dry. As soon as a plate is coated it must be put in a dark place to dry—not even a red light should get to the plates after they are flowed. The place you put them to set should be shaded from all red or white light; a dry plate on a negative exposed for five minutes to a red light will make a transparency; so, of course, will fog if exposed too long to red light in making and drying. The plates will dry in a few hours and are ready for use.

The alcohol and albumen are added to hasten the setting and drying, and also to aid in the flowing. Gelatine and albumen flows more readily than gelatine alone; the albumen also helps to keep the silver in suspension in the gelatine.

To Keep the Emulsion.

Take the emulsion strips and put them into a wide-mouth fruit jar; pour enough alcohol on to cover the emulsion, screw on the top, and the emulsion will [illegible] you wish it, take up what you want to use, wash it to free it of alcohol, let drain and melt. Add albumen, alcohol, and chrome alum as before, and flow the plates.

If you are in a hurry and do not wish to wait the three to five days to gain rapidity, you can take emulsion as soon as all free silver has been formed into bromide of silver. Melt the emulsion, heat to 140° to 150°, add 480 grains of bromide of potassium, and let stand in the water at 140° to 150° for 30 minutes. Set aside in temperature of 40° to 60° to set, and then wash and flow the plates. But if this way is chosen, the emulsion must be washed in a different way than described above, as the soluble ammonium nitrate left in the emulsion will not wash out as in the other process of washing. When the bromide of silver is formed in the gelatine, by placing the silvered gelatine in the brine the emulsion does not take up the soluble nitrate of ammonium, so only needs sufficient washing to free the outside from the nitrate of ammonium. But in the latter case the nitrate of ammonium is all through the emulsion and must be treated as follows:—Squeeze the set emulsion through a piece of coarse canvas into a large bowl of water, take another large bowl, tie a piece of coarse canvas around the top, pour emulsion and water on to the canvas, so as the water will filter off, take emulsion with a silver spoon off of the canvas into another bowl of water; wash this way three times, let drain, melt, add the alcohol and albumen as before stated, and flow the plates.

(*To be continued.*)

DECORATING ZINC.

According to Puscher, a beautiful and permanent dark or light green coating, resembling enamel, can be applied to all kinds of zinc articles, especially those made of sheet zinc, in the following manner:—Fifty parts of hyposulphite of soda are dissolved in 500 of boiling water, and the solution poured at once, in a fine stream, into 25 parts of strong sulphuric acid. The milk of sulphur that separates will soon ball together in lumps and settle. The hot liquid containing sulphate of soda and sulphuric acid is decanted, and the cleansed zinc put in it. In a short time it will acquire a very brilliant, light green coating of sulphide, and only needs to be washed and dried. By exposing it repeatedly and for a longer time to this hot bath, the coating grows thicker and the colour darker and more brilliant. The temperature must not fall below 145° Fahr.; when it does, it should be heated up to 190° Fahr., to obtain a fine and brilliant deposit. By dipping these articles in dilute hydrochloric acid, one of acid to three of water, suphureted hyrogen is evolved, and this enamel-like coating loses its lustre and gets lighter in colour. Aqueous solutions of aniline colours have little effect upon this dull surface and none on the gray brilliant coating. The effect of marbling can be obtained by moistening the gray zinc and applying hydrochloric acid in spots with a sponge, then rinsing it off, and while still wet flowing over it an acidified solution of sulphate of copper, which produces the appearance of black marble. As the zinc has generally a dull surface it must receive a coat of copal varnish. If 15 grammes of chrome alum and 15 more of hyposulphite of soda be added to the above solution, the article will have a brownish colour. The above can all be applied to articles made of cast zinc.

SCIENTIFIC SOCIETIES.

ROYAL MICROSCOPICAL SOCIETY.

The first meeting of the session of this society was held on the 10th inst. at King's College, Strand, the President (Prof. P. Martin Duncan, F.R.S.) in the chair.

Dr. Maddox called special attention to Dr. Steinberg's book, which he regarded as a very great advance upon anything of the kind which had yet been produced. Some of the illustrations, such as plate 12, Möller's typen-platte, were really marvellous specimens of the perfection to which this art has been carried.

Mr. Crisp said that Plate 16 of *Navicula lyra* was also an admirable example.

Mr. Curties exhibited a simple dissecting microscope of unknown American origin (belonging to the Rev. P. Cambridge), which was made exceptionally portable, and was much commended by Mr. Crouch and other opticians present.

Dr. H. Schröder's paper "On a New Form of Camera Lucida," was explained by Mr. J. Mayall, jun., and the instrument exhibited and its construction elucidated by drawings on the blackboard. Mr. Mayall exhibited the camera lucida after the meeting, and it was generally acknowledged to be a marked improvement upon other forms of camera lucida hitherto made.

Mr. R. Brown, jun.'s, description of his object-box was read.

Mr. Crisp called attention to the programme of the 12th annual conversazione of the Chester Society of Natural Science as being admirably arranged.

The President announced that the American Society of Microscopists had informed them that they had elected him an Honorary Fellow of the Society, intimating at the same time that the future Presidents of the Royal Microscopical Society would be considered ex-officio members of the American Society. This compliment was stated to have been conferred in return for the courtesy shown by the Society in electing as ex-officio Fellows Presidents of the American Society.

Mr. Crisp reported the decision of the committee of the American Society of Microscopists on standard eyepieces. He said that he was afraid that the committee had been somewhat misled upon a point of optical theory by the Table of Magnifying Powers published in the *Journal*. This table had now been withdrawn, and he had prepared a paper which there was not time to read at this meeting, explaining the source of the error.

Mr. Squire's paper "On a Method of Preserving Freshwater Medusæ" was taken as read, having been received during the vacation, and printed in the *Journal*. Specimens of medusæ preserved in the manner described in the paper were now exhibited.

Dr. Hudson's paper "On a New Species of Asplanchna" was, for a similar reason, taken as read, Mr. Crisp recalling the fact of the *Times* having placed the letter of the enthusiastic discoverer under the leading articles, and headed it "An Important Discovery."

Mr. E. Lovett read his paper "On an Improved Method of Preparing Embryological and Other Delicate Organisms for Microscopical Examination." A number of mounted objects, as also of the cells in various stages of preparation, were exhibited in illustration of the paper.

The President considered that this was a most excellent process of mounting, judging from the exceptional clearness of the preparations exhibited, which did not show any sign of change whatever. It was also not only a good process, but it was a cheap one, and he had no doubt that many would be only too glad to copy it.

Mr. Stewart said he thoroughly agreed with the remarks of the President as to the beauty of the slides which Mr. Lovett had exhibited. He was also satisfied as to their being proof against leakage; but he thought that it might in some instances be found useful to combine the ground out slide with the cell, because where a plain slide was used the object was apt to get out of the way when placed upon an inclined stage; whereas, if the bottom of the cell was hollowed out instead of being flat, this movement of the object towards the side was often prevented. He should, however, like to ask if any special change had been noticed in any of the objects mounted in this fluid, such as might be due to decalcification.

Mr. Hitchcock said he had been much interested in the paper before them, and having previously seen and examined the preparations, he was able to speak to their excellence. The cement which had been described was certainly very strong. He had been using a very good cement himself for the purpose, though it was not so strong as that which had been described. It was composed simply of common shellac dissolved in alcohol, and though he knew some persons did not like it, he had found it to be most serviceable. After a time it was liable to get rather brittle; but if a mixture of asphalte and gold size in equal parts was applied, it preserved the cement, and at the same time made an excellent finish. He had found this formula very useful in preserving small specimens, kept in bottles. He had also been very much pleased with the preparations of fresh water medusæ exhibited in illustration of Mr. Squire's paper, as there could be no doubt that one great desideratum for microscopists was, some method of preserving those delicate and fragile organisms by which they could be kept in bottles as well as in slides. In preserving this kind of object, at first glycerine seemed to be objectionable, because of its tendency to produce a kind of granular effect; but the alcohol appeared to harden the specimens. He should like to know if this fluid had any effect whatever on the calcareous portions of such objects, and whether the alcohol had any kind of solvent effect upon them?

Mr. Michael said he had been in the habit of using practically the same fluid for some years, and could say from experience that it was a most excellent preservative fluid, and also a very good mounting fluid, when used of various strengths, according to the requirements of the objects to be mounted. If the glycerine was present in any great quantity, it certainly had a decalcifying effect, and he should hesitate to use it for some objects. As to the cell material, he had occasionally used a similar cement, and though he had not used it largely, he had found it very good so far.

Dr. Matthews said that in finishing cells a very good preventive against the oozing out of the fluid was a small strip of the thinnest tinfoil painted on one side with gold-size, and, whilst still "tacky," applied over the junction between the cell and the cover. When this was smoothed down (and it could be done so effectually that it could scarcely be felt afterwards) the result was a perfectly tight connection, which could not possibly break. He might also mention a manner of filling cells with fluid without the possibility of getting any air bubbles inside. It was to have a small trough or cell large enough to allow an ordinary slide to be placed inside it with the cell attached in the usual way; the fluid was then poured into this trough until it filled up to a point a little higher than the top of the cell on the slide. If the object was then placed in the cell and the cover put on, there was no chance whatever of a bubble being included. As regarded preservative fluid, he might also say that he had found syrup a very good substitute for glycerine, as it had no solvent power on calcareous matter.

Mr. Lovett said he had now an experience of three or four years, but had not found any change of form to take place in the objects where proper precautions had been taken in mounting. If very dense fluid was used, it would, of course, be prejudicial to some objects; but if prepared in dense fluid and mounted in light there would be no difficulty. It was important to have the materials good in quality and properly mixed; the best way was to get them prepared by a good chemist, and it was then very easy to mix them with the gold-size. As regarded shellac, he thought it would not do at all for anything containing alcohol. The solution he had recommended would have an effect on calcareous objects if it was too strong; but in the weak form he had mentioned it would be found to have no disadvantage. He had found bubbles in some cells which had been securely fastened down; but he was inclined to regard them as vacuum bubbles, because if they had been air bubbles some of the fluid must necessarily have got out to let the air in. This cement was so perfectly proof against the action of alcohol, that he had used it successfully to stop the leaking of some spirit corks. When an air bubble was caused by the cover being pressed down on the cell so much as to cause some of the fluid to get out, it could be got rid of by pressing it out at the place where the fluid had leaked, and letting the fluid run back again when the pressure was removed, and where there had been any leakage the cement would stop it at once.

Mr. Beck said he had observed from the papers that a strong effort was to be made to establish a Natural History Station somewhere upon our coasts, and he wanted to ask if it would not be possible for them, as a Society, to promote the formation of such a station. Whether this could be done by means of a money grant, or otherwise, was of course a question for the Council, but he should like to see the Society put itself forward in the matter.

The President said he had no doubt that if this proposed station was formed it would be under the control of the Science and Art Department, and, as such, it would be a Government institution. Such an institution would probably imitate the foreign stations already established, but whether their Society could do anything in the way suggested, he was at present unable to say.

The following instruments, objects &c., were exhibited:—

Mr. R. Brown, jun.: Object-box.

Mr. Crisp: (1) Swift's Radial Microscope; (2) Mirand's Revolver Microscope; (3) Pelletan's Continental Microscope; (4) Fol's Compressorium; (5) Möller's Typen-Platte, with 400 diatoms, having the name of each photographed beneath it; (6) Fresh-water Medusæ preserved by Mr. Squire's process.

Mr. Curties: American Portable Dissecting Microscope.

Mr. Lovett: Slides of *Cottus quadricornis* (one day old); Ova of *Doris tuberculata*; young Diadem Spiders; various Crustacea; young of *Asteria gibbosa*; leaf of *Drosera rotundifolia*, with insect and *Bryum hornum*, mounted by the process described in his paper.

Mr. J. Mayall, jun.: Dr. Schröder's new Camera Lucida.

Dr. H. Van Heurck, of the Botanical Garden, Antwerp, was elected an Honorary Fellow of the Society.

In the action of "Otto v. Ashbury, Sumner, and Co.," and "Otto v. Ogden," and "Otto v. Bickerton and Co.," which were actions brought by Mr. Otto to restrain infringement of his patent No. 2081, 1876, the respective defendants have submitted to orders for a perpetual injunction in terms similar to those of the judgment given by Court of Appeal in favour of the same plaintiff, in an action of "Otto v. Linford," brought to restrain infringement of the same patent. And, further, in the similar action of "Otto v. Whittaker," judgment has also been obtained for an injunction.

SCIENTIFIC NEWS.

With the dark evenings towards the end of this month and the beginning of November, observers will have a good opportunity of detecting Comet Pons, and even when the moonlight increases next month, the comet will then have become so bright that good weather will probably enable it to be seen. The ephemeris for Greenwich midnight during the next ten days or so, according to MM. Schulhof and Bossert's corrected elements, reads thus:—

	R.A.	N. Dec.
	h. m. s.	° ′
Oct. 26.	16 54 1	53 40·4
28.	16 57 27	53 17·7
30.	17 1 5	52 55·3
Nov. 1.	— 4 56	52 38·1
3.	— 9 0	52 11·2
5.	— 13 18	51 49·4

The brightness is now about three times as great as at the time of discovery, and by the end of November will be about five times as great, always supposing the comet has not undergone any material change since its last visit. The course indicated will take the comet near Beta and Gamma Draconis, with which it will be in conjunction on Nov. 11 and 20, passing about two degrees south.

It appears that Jupiter was not seen entirely without satellites as predicted for Oct. 15. The third satellite was visible at the east limb at 3h. 56m. a.m., and about the same time the fourth made its appearance on the west limb. Several correspondents send notes of their observations, which show that the times given in the *Nautical Almanac* must be wrong.

The maximum of the sunspots occurred last year; but they have been decreasing much slower than the previous increase, and some very large spots have been visible lately.

According to Profs. Roscoe and Balfour Stewart, the annual value of the sun's heat is greater at Kew than at London, in the proportion of 100 to 58.

The Ben Nevis observatory was formally opened last week. The altitude is stated to be 4,406ft., the United States possesses two observatories of the kind, one Pike's Peak, at an elevation of 14,151ft., and the other Mount Washington, 6,286ft. Italy has three, the elevation ranging from 7,087ft. to 8,386ft.; France four, ranging from 3,989ft. to 12,199ft.; and Switzerland two, of 2,875ft. and 7,505ft. respectively.

The general conference of the International Geodetic Association, held at Rome, to discuss the question of an initial meridian for the unification of longitudes, and for the unification of time by the adoption of a universal hour, presented a report in favour to the special committee, and it is understood that Greenwich as the initial meridian was accepted by six to one. Greenwich time for the universal hour was adopted unanimously, but on the question of noon or midnight there was a division of five against two. The longitudes will thus be reckoned from Greenwich, in one direction from east to west, from zero to 360°; and the mean noon of Greenwich will thus correspond with midnight at 180°, where the date will change. As the United States, Germany, Austria, and Italy use the Greenwich meridian in navigation, Dr. Hirsch was probably correct in stating that 90 per cent. of navigators calculate their longitudes from Greenwich, and as so strong an expression of opinion was elicited, the way is paved for a settlement of the question at the International Congress to be held next year at Washington.

The Meteorological Society have received permission to adopt the prefix Royal. We suppose that in future Fellows will append to their names the letters F.R.M.S., and thus they will be indistinguishable from the Fellows of the Royal Microscopical Society.

The death is announced of the distinguished geologist, Joachim Barrande, at the age of eighty-three. He was a Frenchman by birth, but had resided during the greater part of his life in Prague, the Silurian basin of which he made classic ground to geologists. The Geological Society in 1857 awarded him the Wollaston medal.

The death is also announced of M. Alfred Niaudet, a well-known French electrician, at the early age of forty-eight.

The next meeting of the Institution of Mechanical Engineers will be held at Birmingham on Thursday, November 1st. The following papers will be read and discussed at the meeting: "On the Inventions of James Watt, and his Models preserved at Handsworth and South Kensington," by Mr. Edward A. Cowper, of London, Past-President; "On Fuel Consumption in Locomotives," by M. Georges Marié, of Paris; and "Experiments on Friction," report of the Research Committee.

An electric light worked by primary batteries has been recently exhibited, and the consequence is the appearance of some extraordinary notices. It is stated that 18 lamps, equal to 160-candle power, suffice for a Pullman car, the weight of the battery not exceeding 3½cwt., whilst its duration for a single charge is from 20 to 25 hours. The cost of working is also stated to be not more than that of gas. It is further said that the system is in experimental use on the Great Northern Railway.

Anyone desirous of obtaining an idea of a complete system for the generation and utilisation of electricity will find it in a specification recently published of a patent issued to Mr. J. S. Williams, of Riverton, N.J. It contains sixteen pages of drawings, 96 figures, and 76 pages of matter. The price is 3s. 10d. For such a patent as that, £25 is not too much to pay in fees; but it is not quite complete, as the patentee refers to two specifications of 1881 and nine of 1882, so that he has been a good customer to the office.

By direction of the Board of Trade, Mr. H. Reader Lack has issued preliminary rules for taking out patents, and has appended to them a "note" which settles the dispute as to the "practice" of the office in view of the now famous sub-section 3 of section 45 of the new Act. "Applications for letters patent made during the present year must be proceeded with in accordance with the existing laws and rules." The result of the blunder will now be a rush of would-be patentees in January, and a "block" in the office.

Dr. Hermann Wedding, of Berlin, points to the fact that when melted cast iron is allowed to chill, the first crystals which form are nearly pure iron. He suggests that by repeatedly crystallising the iron a metal of high character may be obtained from poor pig iron.

The Midland Railway Company has just bought all the Pullman drawing-room day cars now running over its line. From 1st November they will be used as first-class cars, without any extra charge being made for riding in them.

The Great North of Scotland Railway Company has adopted the Westinghouse as the brake of its system.

The West Coast Joint Stock vehicles are being fitted with both Westinghouse and vacuum brakes in place of the chain.

Mr. Clement L. Wragge, F.R.G.S., F.M.S., sailed in the steamer *Maranoa* on the 18th inst., for Adelaide, South Australia. He takes with him a valuable equipment of astronomical, meteorological, and surveying instruments, and intends to make the utmost of the voyage, and of all his travels, in a scientific point of view. A fine equatorial refracting telescope is a great feature in his equipment.

Secondary Batteries as "Empties."—In these days of school boards and science departments, of examinations and certificates, it is hard, says the *Electrician*, to realise the following: The Electrical Power and Storage Company had occasion recently to lend a secondary battery charged and ready for use. For the carriage the railway authorities claimed 22s. 6d. The battery was used and returned, the railway authorities now claiming 17s. 6d. A remonstrance was made as to the excess of charge in one direction over that in the other, which was met by the reply: "Oh! but the cells were fully charged going, and returned empty, hence the difference in the carriage."

For an etching liquid for steel the following is given:—Mix 1oz. of sulphate of copper, ¼oz. of alum, and one half a teaspoonful of salt reduced to powder, with one gill of vinegar and twenty drops of nitric acid. This liquid may be used for either eating deeply into the metal or for imparting a beautiful frosted appearance to the surface, according to the time it is allowed to act. Cover the parts it is necessary to protect from its influence *with beeswax, tallow,* or some similar substance.

LETTERS TO THE EDITOR.

◆

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the Editor *of the* English Mechanic, 31, *Tavistock-street, Covent-garden, W.C.*

All Cheques and Post-office Orders to be made payable to J. Passmore Edwards.

⁂ *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

> "I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original."

THE "MIDLAND FREE PRESS" ON ENDOWMENT—THE ATTRACTION OF THE EARTH BY MARS—CLEANING OBJECT-GLASSES — SATURN — MESMERISM.

[21953.]—So effectually has your contemporary, the *Standard*, disposed of Prof. Ray Lankester, that my first idea was to leave that gentleman's "I humbly beg your pardon, Keyind State; but have you got such a thing as a few millions about you to bestow upon a pore biological researcher?" address, at the British Association, wholly unnoticed. Through the kindness of my brother correspondent, Mr. Franks, however, I have received (through you, Sir) a cutting from the *Midland Free Press* of the 29th ult., which illustrates so excellently the way in which journals of all sorts are "got at" by the Endowment of Research gentry, that I feel constrained to devote a few lines to the subject. "Science," the Leicester Mentor tells us, "goes in rags, while superstition flaunts in purple and fine linen. A scurvy grant or two to such institutions as the Science and Art Department and the British Museum, and an occasional subsidy for a Transit of Venus or a deep-sea dredging expedition, represent all the Government can think of doing for the encouragement of scientific research"—and so on. In connection with this, I would venture to point out that, while I verily believe that the nation gets at least twenty shillings-worth for every pound bestowed upon the British Museum, I have no hesitation in affirming that it is simply plundered for the benefit of a clique by the Science and Art Department. Why, it is only in your number for the 5th instant ("Scientific News," p. 105) that you reproduce from Mr. Crowther's letter the most startling statement that "the department annually obtains from Parliament £340,000, or thereabouts, out of which only 5s. 9d. in the pound is given to the direct encouragement of national science and art instruction, the remaining 14s. 3d. being 'absorbed' at South Kensington and Dublin." In other words, 71 per cent. of the sum lavished on this precious "department" sticks to the fingers of the gang of harpies at headquarters before scientific and art education generally benefits by the outlay at all! Furthermore, the Leicester luminary is as vague and wrong in his other statements as he well can be. I somehow seem to remember a certain Meteorological Department for which the Government pays £15,000 a year or so, whereof £1,000 is annually divided among certain Fellows of the Royal Society (to their lasting discredit), who are dubbed the "Meteorological Council," as an excuse for their genteel form of national pocket-picking. I further seem to recollect the subsidising of every one of the more recent expeditions to observe total solar eclipses; and unless my memory is more than usually treacherous, that most paltry and contemptible sham the "Committee on Solar Physics," also robs the Treasury annually. With reference to Transits of Venus, I may remark, *en passant*, that the gentleman who says his lesson in the columns of the *Midland Free Press*, writes as though Venus crossed the Sun's face every six months or so. It would seem, moreover, that the wicked, unappreciative State not only starves the British Museum and the Science and Art Department, but actually sanctions "schemes for plundering" science "of valuable property, which private beneficence had bequeathed for its exclusive benefit"; an illustration of which is found in the (alleged) fact that "nearly the whole of the splendid bequest made by Sir Thomas Gresham for scientific purposes, two hundred and fifty years ago, has been annexed by the Tammany Ring known as the Corporation of the City of London." I am assuredly not concerned to defend the London Corporation; but the idea of any upholder of the Brompton imposture applying the designation of a "Tammany Ring" to the Patres Conscripti of the City, is really "too-too." Then, as a matter of course, we have the example of Germany flourished before our eyes, and are informed—for the *n*th time—how research is "endowed" there. Somehow, though, we are *not* told the amount annually paid to each of the workers in the German laboratories of research; and for a very simple reason. The greedy, pushing, impudent, and noisy clique who are clamouring in this country for their "researches" to be endowed, have no thought or idea whatever of accepting the modest pittance with which a German Professor is content. They want "Solar Physical Observatories," and the like, with salaries attached which would afford a modest competence to at least a dozen of their German exemplars. Plodding on for the sheer love of truth at wages just sufficient to keep them above want, is very, very far from the notion of these gentry. To travel *en prince*, to "borrow" foreign scientific apparatus, or to go forth in luxury with packages labelled "English Government Expedition," to astonish the weak nerves of douaniers and the like—this is the sort of way in which they fondly hope to rob the struggling British taxpayer. But, says in effect, the author of the article on which I am commenting: Take the hard earnings of even the poorest contributor to the Revenue, lavish them in such expenditure as this, and the Millennium will come immediately—or sooner. "Then," exclaims this genius, in a fine burst of peroration, "then, and not till then, will the millions of money at present annually wasted in the propagation of error and barbarism by means of priests and soldiers be devoted to the noblest of all human occupations, the search after truth." Believing, as I do, that if the Church and the Army were swept from the face of the land to-morrow, the resulting chaos would afford but scant opportunity for "the search after" anything but the personal safety of the law-abiding and God-fearing citizen, I am quite prepared to endorse the words with which the *Midland Free Press* concludes: "Professor Ray Lankester, however, will have to wait a long time for the realisation of this pleasant anticipation." The article which has formed the text of my remarks would seem to have elicited a most able and incisive but temperate reply from your own excellent contributor, Mr. Franks, which I will not spoil by attempting to make a précis of, or by picking out disjointed paragraphs from a closely-reasoned sequent composition. Mr. Franks might with great advantage re-write and expand it in a form suitable to these columns.

If "J. M." (query 51951, p. 138) has access to any recent work on astronomy which gives the masses of the planets, he has only to compare the mass of the Earth with that of Mars, and do a rule-of-three sum in the following form:—Mass of Earth : mass of Mars :: Earth's attraction of Mars : attraction of Mars on Earth.

With reference to query 51961 (p. 138), I would say that I see no objection to wiping the inner surfaces of the lenses of an object glass once or twice a year with chemically-clean cotton wool wetted with absolute alcohol, and polishing them with a very carefully chosen piece of clean wash-leather. I use my own telescope at night, nearly as often, I take it, as "Achromatic" himself; and make a point of exposing it to the sun next morning whenever he is shining. It is surprising how effective this treatment is in preventing "speckles"—et id genus omne. I cannot fancy that practical opticians, like Mr. Lancaster and "Prismatique," will view the repeated rubbing and cleaning of a valuable object glass with any more favour than I do.

As Mr. Franks criticises (in letter 21925, p. 147) the reproduction of his drawing of Saturn on p. 126, I should like to ask him further whether it fairly represents the inner outline of the crape ring C? I put this question because the engraver has shown the crape ring as of absolutely equal width all round, in defiance of perspective, and as though he were giving an isometrical projection of it. As a matter of fact, I always see it decidedly wider in the ansæ, its inner edge being much nearer the planet's equatorial limb than the woodcut shows, and, possibly from insufficient optical power, not forming a rigidly continuous elliptical curve with the part crossing Saturn's face. Cassini's division, too, is much too narrow and inconspicuous in the engraving.

And, apropos of Saturn, I shall be delighted to furnish Mr. Mills (letter 21928, p. 148) with an outline of that planet under its present aspect, from which he may cut a stencil plate. I must, however, beg him to wait for another fortnight; inasmuch as I have not even a pair of compasses at the place whence I am writing. I hope to be at home by the day on which this will appear; but that will be too late for my present letter.

I may say very briefly, in reply to the question which "Sigma" puts to me (in letter 21935, p. 149), that I have witnessed exhibitions of mesmerism in which the volition of the operator was (apparently) the sole motive power in the production of various effects upon the subject. Moreover, I have seen a lad in a cataleptic or quasi-cataleptic condition support a pretty heavy chair at arm's length for a time during which I, a powerful man, should have been sorry to have held it, and to endure pricks of a pin with the most imperturbable stolidity. I could, however, never satisfy myself whether these phenomena were not partly the result of training, and partly subjective. They were exhibited for payment, and we know the tendency of those who display such things to "assist nature." Less fortunate than "Sigma" in all the private mesmeric experiments I ever made, I came definitely to the conclusion that every result I obtained was certainly a subjective one, and that beyond exciting the necessary mental condition of attention and expectancy in my patients, my own share in the matter was *nil*. I only give this, however, *quantum valeat*, as my own personal experience.

A Fellow of the Royal Astronomical Society.

STARS IN CAMELOPARDALIS—THE SPECTROSCOPE.

[21954.]—With respect to letter 21930 (p. 148), I would just remark, at the outset, that, because a certain double star does not appear in Webb, it is not safe to jump to the conclusion that it is *new*. Amidst the vast number of doubles at present known, those in "Celestial Objects" only profess to be a careful selection of the most interesting. Possibly the star referred to may be Σ 397, 3h. 24m. + 59° 59′: 8·7, 10·5 : 42·6° : 5·1″. Should this not agree, if Mr. H. will examine it again, and carefully estimate its distance in R.A., and difference of decl., from Σ 385, also some guess at its position angle, I will try to identify it.

The latest measures of Σ 400 that I can find are those by Seabroke, of Rugby Observatory, as follows:—304·9°, 1·56″, epoch 1880·08; and 301·0°, 1·39″, epoch 1880·11. And may I beg of Mr. Holmes, when speaking of Struvé's stars, to always prefix "Σ" to the number? There is, then, no need to give the constellation, or even the R.A. and decl., the Struvian number being sufficient for identification.

I regret to say I cannot see my way clear to sending a description of my stand to the "E. M.," as it would involve a *diagram*, and I decline to let the engraver play tricks with it. But if Mr. Holmes will "hark back" to old vols., he will, doubtless, find something suitable for his purpose.

Would Mr. Pearson (letter 21932) kindly indicate the cause of failure in my attempts to see the solar prominences? My spectroscope is a direct-vision, of 5 prisms (3 + 2); and gives very brilliant star spectra with the 11¼in. telescope. When used on the sun an observing telescope is fitted to it, and it then clearly divides the D line. I have tried on several occasions to catch the prominences, but without success. I carefully followed the usual directions, bringing the slit accurately in the focus of mirror, and focussing sharply on the line which separates the atmospheric and solar spectra; but no bright lines could I detect in the former. The slit was tried both radially and tangentially to the limb, with narrow slit and wide ditto, and with or without a screen of ruby glass—to isolate the bright C line—but all to no purpose. I ought to add that an eccentric stop was used, varying between 2¼in. and 4½in., as I could not endure the intense brilliance of the spectrum with full aperture. Does the fault lie in the smallness of dispersive power, or what?

W. S. Franks.

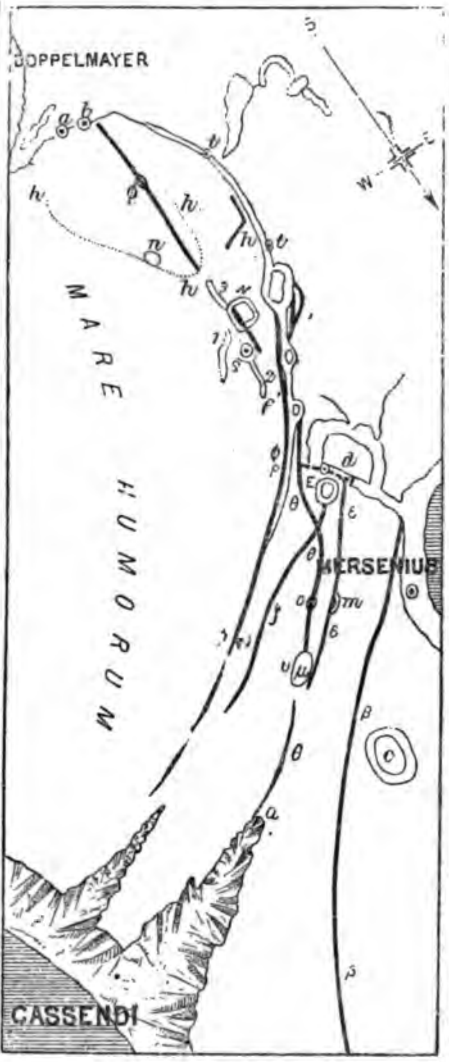
CAMELOPARDALIS.

[21955.]—The double star I referred to following 385 is just 5′ directly following that star. I now add R.A. 25° and distance rather over 3′. Bad weather renders any estimate of magnitude valueless.

Edwin Holmes.

SELENOGRAPHICAL—CLEFTS ON THE E. SIDE OF THE MARE HUMORUM.

[21956.]—These remarkable clefts were well seen between 7h. and 10h. on October 12th, the E. wall of Mersenius being on the terminator, and as published drawings fail to show them with clearness, on account of the necessarily small scale adopted, and omit some which undoubtedly exist, I herewith send a diagram of them made at the telescope, together with a brief description. The longest and most distinct of these clefts is the great Gassendi rill, β, which appears to originate at the foot of the ridge connecting Mersenius with the Ring-plain d, and, passing Mersenius C on the west, to extend far away northwards into the region E. of Gassendi. The cleft ϵ was traced from the N.W. wall of d, in which it makes a very distinct notch, to the ϵ side of a crateriform object V, traversing on its way the craterlet m. Commencing on the N.W. side of the small crater E and proceeding towards the N.W., a third cleft, η, was noted as very delicate. A fourth cleft θ, originating apparently at the craterlet f', was traced across the last, and, after passing through the object c, seemed to terminate at v. A probable N. extension of this cleft (also marked θ) is shown extending to the mountain mass, Gassendi a; but it is not clear whether it does not belong rather to the cleft E. The fifth cleft, ϕ, was observed from Mersenius g almost up to the well-known spur which projects from the S.E. wall of Gassendi. Mersenius g, f, and the craterlet f' are connected by a prominent bright ridge which stretches in a bold sweeping curve towards the N.W., and the cleft ϕ runs at the bottom of a shallow valley on the E. side of it—one of the few instances on the moon's surface of such a close connection between a ridge and a rill. This ridge is prolonged on the S. side of g (but without its accompanying cleft) and forms the E. boundary of a kind of bay in the Mare Humorum, very similar in character to Doppelmayer, and, like the latter, presenting all the appearance of having once been a complete formation. The dotted line h, h, h marks its W. boundary, which under oblique light is plainly indicated by a dark band much deeper in tone than the colour of the surrounding Mare. A low mountain, n, probably represents a portion of the original wall. Crossing this bay in a meridional direction is a distinct cleft, Doppelmayer ϕ, which seems to terminate where it touches the dotted line h. A ridge, 3, prolongs its direction towards the crateriform object Z. Another well-marked cleft cuts through the W. side of Z and ends on the E. side of a small bright craterlet s, which is surrounded by an ill-defined glow. A second ridge, 2, extends from this object towards the N., and a third ridge, 1, lies on the W. side of it. On the E. side of the ridge which connects g and f are two short clefts, δ, δ', which, having a common point of origin S. of f, spread out like the sticks of a fan to the N. wall of g. On the N.W. wall of Mersenius d is a delicate crater-rill which appears to commence at the notch referred to above as forming the S. termination of the cleft ϵ and, crossing the cleft θ at right-angles, to join the ridge and cleft ϕ at the point p. My diagram is on too small a scale to show this interesting feature properly; but it was very distinctly seen.



The instrument used was an 8½in. reflector by Calver, powers 350 and 400.

Thos. Gwyn Elger.

Kempston, Beds, 13th Oct.

THE WEATHER AND THE TIDES.

[21957.]—The effect of atmospheric pressure, both as regards magnitude and direction, in raising or depressing the level of the sea, and by consequence the heights of the tides which traverse it, is a subject of instructive interest and of much practical importance; and yet it is one which few care to investigate thoroughly, and one in reference to which there prevail very widely-extended misconceptions. A cursory acquaintance with the facts warrants people in asserting that "the tides are greatly influenced by the winds," and if by this expression is included and implied that which gives motion and force to the winds, namely, barometric pressure and direction and steepness of gradients, the statement has in it a considerable amount of truth; but a distinction must be drawn between the two effects. The tempest hurrying over the surface of the water has power to create huge foaming billows, to the terror of the mariner, and to that its surface action is limited; but the change in atmospheric pressure, which causes vast currents of air to slip as down an immense inclined plane, has power to alter the sea-level, and thus to produce on our coasts an increased or diminished range of tide. That this is the case will appear at once from the circumstance that very often the tide rises or falls beyond its predicted boundary when no storm is present at all, the only constraining force being the altered pressure of the atmosphere, as shown by the rise or fall of the mercury. It is perfectly true that in this respect the ocean is a water-barometer, and it is to be hoped that the time is not far distant when more attention will be paid to its indications; yet, in order that correct prognostics may be made, it is absolutely necessary that the normal height of the tide should first be correctly ascertained—that is to say, its height under specified atmospheric conditions. Twelve years' experience enables me to say that this can be done, and done efficiently, so that now an estimate can be formed within very approximate limits of the height which will be attained by any tide from the observed number of inches which were required to be added to or subtracted from the tabulated height of the tide immediately preceding. The meteorological aspect of the weather is perpetually varying, and a reference to the charts daily published by the Weather Office is most useful; but in order to get at a practical result, regard must be had to the actual deviation of one tide after another from the specified height, which belongs to a specified height of mercury with a level gradient. For example, I take four tides in succession correctly computed in the Admiralty tables for Liverpool.

Date.		Calcd. ft.in.	Obsd. ft.in.	Bar.	Wind.
1883.—Sept. 3.	Even.	26 9	26 9	29·9	slight.
4.	Morn.	27 5	27 6	,,	,,
4.	Even.	26 5	26 6	,,	,,
5.	Morn.	26 7	26 6	,,	,,
5.	Even.	25 6	25 6	,,	,,

In this case we have a steady barometer at the standard height and a level gradient. But now I produce results obtained with a barometer high, but steady, and pressure from the north, by which, therefore, the sea level is depressed; and it is seen how continuously that depression is maintained so long as the atmospheric conditions are stable.

Date.		Calc. ft. in.	Obsd. ft. in.	Error. in.	Bar.	Wind.
1883. Oct. 6.	Morn.	24 3	23 10	– 5	30·3	N. slight
6.	Even.	23 10	23 5	– 5	30·4	,, ,,
7.	Morn.	23 0	22 8	– 4	30·5	,, ,,
7.	Even.	22 10	22 6	– 4	30·5	,, ,,
8.	Morn.	21 9	21 5	– 4	30·5	,, ,,

Again we select from tides raised by atmospheric action, and the same persistence is still observed when the barometer is low.

15.	Morn.	21 2	22 3	+ 11	29·7	S.W. ,,

A curious circumstance which has been noticed repeatedly is this, that the sea rises several hours before the gale approaches; and yet this is only to be expected, inasmuch as the water expelled from one region of the ocean must at once bend its course to another, and all motion requires time for its accomplishment. On the same principle, at the season of equinoctial tides, the lowest ebb is that which occurs 2½ days before the highest tide, and not the ebb which immediately precedes or follows.

James Pearson, M.A., F.R.A.S.

Fleetwood Vicarage, Oct. 8.

"PRACTICAL NOTES ON PLUMBING."

[21958.]—In reply to Mr. W. Fyfe's letter (21910), I have only to say that I have simply shown a distance pump, and for an illustration I have used the figures, say, 300 yards and 18ft. Here Mr. Fyfe has thought proper to take up quite an unnecessary line of argument for the simple reason that I have not in the slightest degree even hinted, otherwise than approximately, anything about the *proportions*, only as by way of an illustration, taking it *for granted* that anyone requiring such an engine or pump would employ a plumber of sufficient sense and skill to work out the machine in suitable proportion to that required. I contend that I have said sufficient in my articles to enable any intelligent workman to make the pump in question without my having to clutter pages away touching well-known details, and the whole body of physicks. What does it matter if I have not told my readers that the pump and pipes can be filled with a forcepump? Everybody capable of reading the article knows what a forcepump is, and also knows how to fill a pipe (*full too*, without having to resort to force pumps, and I, as a maker of the pump in question, say that such is not wanted; but let this stand. I will speak of the weighted plunger. Here, according to Mr. Fyfe's own writing, it is possible for such a machine to work, and I am certain that I have said sufficient to instruct any thoughtful mechanic. Have I not used these words—that it must be weighted sufficiently to allow for friction, and a fair allowance for putting the water into a *moderately quick motion!* Now, what would Mr. Fyfe have me to say? Would he have me give the weight of plungers for columns of water and pumps ranging from one foot to 100ft.? I contend that if I were to do so my readers would soon be very limited, and my articles (which I now consider too long) would never be ended.

Allow me to tell Mr. Fyfe that he has candidly confessed that the thing can be made to work, and he having seen in the article in question all I required my readers to see (I thinking that the other articles would be taken into consideration), he should not think himself better than others; for if he can work out this simple question as to the size of the plunger, &c., surely others can.

Some of my drawings would be pretty-looking things if they were all drawn to scale, simply because you would not be able to see many of the parts; besides, there is not the slightest reason for such work. The drawings are simply to illustrate the article, and never intended for measurements, nor have I even ever hinted such a thing.

With regard to the figures in No. [illegible], page 47, column 3, which I have not just at present at hand, the column should have been 60ft., not [illegible], and if printed as Mr. Fyfe states, there is not the slightest doubt but that they are wrong; but such a glaring mistake at once suggests itself, and any one capable of doing pumpwork would instantly see that it is a mistake, especially if they look at the figures above and below. The figures [illegible] if niceties are required, [illegible] would reckon 272·5lb. for a [illegible] and 326·30 for a 60ft. column, so that even Mr. Fyfe's figures (viz., "90lb. too much"), are not correct, although he has put it out as a [illegible] the above figures I can prove to be [illegible] yet there is a difference. Can Mr. Fyfe explain this enigma, and tell me where such hair-splitting would be of any practical use to the plumber who is satisfied with the reckoning ½lb. to 1ft. column of water?

Now refer to line 22, right-hand column, page 128 of his letter. He there refers to the suction water column not having time to stop. Why should I give "the exact conditions as to distance, depth, &c."? Sufficient it is for me to state that such is the case; that is, presuming that my readers are acquainted with the common laws of natural philosophy. Say that the column of water is drawn 18ft., horizontal distance of pipe to be 22: 22 + 18 = 40; say that its velocity is 1ft. per second, size of suction-pipe 1½in., which will at this velocity discharge [illegible] gallons per minute. Now, suppose the barrel to be 4in.; here the water travels at a speed of 1ft. per second; but suppose the perpendicular height to be say 4ft., and the horizontal distance to be 2ft., how work the handle of the pump, say, for argument's sake, so as to produce a velocity of 2ft. per second continuously, what time is there for the water to stop, clack to close, water to start, and clack to open? I have distinctly stated in my article referred to, that to effect a continuous stream, the handle must be worked (when giving the back stroke) very suddenly, like so many snatches. This, I consider should have been sufficient for any intelligent plumber's boy to understand, and why the question is here raised is past my comprehension. Speaking of momentum, I see there is a mistake by printing minute for second—this Mr. Fyfe has, I am pleased to say, pointed out. He also very kindly tells us that we cannot get a velocity of 6ft. per second through a suction pipe. I never said we could; but by way of illustration mentioned "a column of 40*lb. weight*, whose velocity is 30ft. *per minute* (which, of course, we all know should have been second) would, if suddenly checked, &c."

Now, with regard to the pump tables, Mr. Fyfe states that "they all refer to products above the hand, not a word on the tail pipes, or what part the atmosphere or friction plays in the matter." Now, with regard to the atmospheric work, allow me to say that the word "lift" of the water is what it signifies—simply the perpendicular lift from whence you bring it to the place where you deposit it, and I have said so in more than one place in my articles, which if I were to be continually repeating every time I have occasion to write upon the subject, I should have nothing else to do.

With regard to fractional parts, I have to say that they are not taken into consideration by the plumber when fixing a pump, nor is it in the least degree necessary for him to do so. Remember, I have allowed sufficient margin for everything, and that which is universally acknowledged by the trade as the working rule—namely, in a column of water 1ft. high, having the square inch for its base, I have allowed ½lb. This is sufficient for overcoming the friction in the vertical length of pipe, providing the sizes are taken into consideration.

We say that a column of water produces a pressure in pounds per square inch equal to about three-sevenths the height, or including the friction in the pipes it may be roughly taken at one-half. Thus a column of water [illegible] will produce about [illegible] [illegible] the temperature of the water, and, generally, for the exact [illegible] we proceed thus:—

A gallon of water at [illegible] weighs [illegible]. A cubic foot weighs [illegible] and contains [illegible] nearly six and a quarter gallons. Now, knowing this, it is a simple enough to get at the pressure of a column of water whose base is one square inch and height one foot.

A [illegible] working [illegible] water [illegible] square, will balance a column of water within a [illegible].

[illegible]

[illegible] Now [illegible] and say the pipe [illegible] through [illegible] which may be calculated by the following rules:—

G = ([illegible] H)

H = ([illegible])

[illegible] = ([illegible] H [illegible])

L = ([illegible] H)

In these rules D = diameter of pipe in inches.
H = head of water in feet.
L = length in yards.
G = gallons per minute.

Mr. Fyfe should know that, when writing articles suitable for the plumber, simplicity is the thing wanted, and I contend I have from time to time made my writings [illegible] suitable for the class of work that I [illegible] I [illegible] my works with algebraic rules and other formulæ requiring the use of [illegible]. Of course, Mr. Fyfe's [illegible] numbers in figures, &c., will always be appreciated by me, as the [illegible] can [illegible] than [illegible] but they would be more useful if given at the time.

P. J. Davies.

LIFE AND MATTER.

[21[illegible]]—Let us give a little further consideration to the dogma offered to us by "F. W. H." ([illegible], p. [illegible]), on the authority of Büchner, who appears to be regarded by him much as the orthodox do Moses or Paul, as he indicates that a quotation from him is to be received with the same humble acceptance as a text of those other authorities. Büchner, it appears, says, in "Force and Matter," p. 185: "Now in the same manner as the steam-engine produces motion, so does the organic complication of force-endowed materials produce in the animal body a sum of effects, so interwoven, as to become a unit, and is then by us called spirit, soul, thought."

Well, if the action of the steam-engine is to explain that of a living thinking man, we must needs first ascertain, *What is a steam-engine?* Is the steam-engine merely an organised mass of matter, iron, brass, &c., vitalised, so to speak, by the steam which conveys to it the energy of the fuel? This is a fair analogue of the animal body converting the energy of the food. But is this all that a steam-engine is? Not by a very long way. How came that "organic complication of force-endowed materials," the steam-engine into existence? Did its parts frame themselves by ever so prolonged a course of evolution? That its present construction is the result of long and gradual evolution we know; step by step it has become more and more complex, its action more and more automatic; just so has man, if we trace his evolution to that ancient marine ascidian, or even further back to a primary amœba. But—was the evolution of the steam-engine from within? *Was it the result of the actions of the matter and the forces which constituted it at each stage of its development?* Where is the "great German scientist" who dare ask us to accept the monstrous notion? and why are we to accept the same idea as to the man, which he tells us is constituted in the same manner as the steam-engine?

The steam-engine is the embodiment of the will and thought of its designer; these—not the matter and the force—are its ultimate source: they are its origin, not its product. But let us go a step further in our inquiry. "What is a steam engine?" The *engineer and stoker are essential parts* of the steam engine, as constituting a complete agent. Their controlling power was taken into account by its designer, and is essential to its working. That "unit which we call spirit, soul, and thought" is to the man just what the stoker and engineer are to the steam engine: if we can truly say that "the organic complication of force-endowed materials produce" in the steam-engine the unit we call the engineer, then—and not till then—we may say the same of that inner agent which all the wisest of mankind have agreed to consider is the true man—the spirit acting through the body.

And so of all life. Never have we yet seen matter and force constitute a living organism. Every supposed case of self-generated life has been traced to blunders of the observer, and not the most ultra-materialist dare assert that non-living matter has become living, except through the action of a living organism, much as he may long to do so. In the face of this, it is not within the lines of justifiable hypothesis to talk of the possible "synthesis of life." When Mr. Grey says to me, "It may not come in your time or mine, it may not come for centuries; but it *might* come to-morrow," I might, with equal propriety, use the same words as to a proposed excursion to the moon. Such an excursion is conceivable: an eminent scientific writer (Jules Verne) has even shown us a mode; still I do not expect ever to make one of the party; but I am quite sure of one thing, that such excursions will be as common as trips to Egypt are now, ages before the first synthesis of life has been effected.

It is very natural for uninstructed people to say "Oh, but you cannot limit the powers of science." But Mr. Grey ought to be above such clap-trap as that. We do know well enough some of the limits of scientific possibilities, and he must know that the step between the organic product and the organised being is so vast as to be nearly infinite; nothing bridges it but the imagination of the materialist who wants nothing but his own presumption to found an hypothesis on.

Organic chemistry may be independent of life; that is to say, we may produce organic substances direct from their material elements. I am quite ready to admit that some day we may make sugar from carbon, hydrogen, and energy; but sugar is a crystalline substance, a product of vital processes, not organised or living. We might make a good silk fibre for all I know; the silk fibre is not organised, it is a viscous substance collected by the worm, and mechanically spun out, just as we make lead pipes by the hydraulic press; we can dissolve silk, and, no doubt, could respin it. We can also dissolve cellulose, say, cotton fibre, and, no doubt, could from it reproduce *a fibre*, but not a cotton or a linen fibre, because these are organised structures; so we might make cellulose itself, the chemical substance, yet be no nearer the formation of a single cell, such as "life" builds out of it.

Have we not, then, the right to conclude that there is some absolute distinction between living matter and non-living matter; or, more truly, are we not bound to admit this by the necessity of honest reasoning? And this applies not only to the human life—endowed with thought, to the animal life—possessed of volition, but also to vegetable life, to the hyacinth bulb, and the ultimate cell capable of subdivision and reproduction. If it is said, by way of reproach, as Mr. Grey has said, the mystery is "not rendered one iota more clear by the assertion that life is a principle differing entirely from matter," I submit that the reproach is unmeaning. I have started with the admission of an unfathomable mystery, before which all wise men and all true science stand silent, in conscious ignorance. But are we bound to have *no mystery?* Are we to invent make-believe explanations, in order to pretend that we understand all things? Say that thought is a motion of matter, that life is a function of matter and energy, that spirit is the result of organic complication of force-endowed materials. What are all these but *forms of words without a meaning?* Do they assist anyone to form an idea of the things themselves? Truly we may say of those who thus wrap up their ignorance in sounding phrases, "Who is this that darkeneth counsel by words without knowledge?" Surely it is truer wisdom to accept a mystery, than pretend to explain it by a form of words conveying no ideas.

For, let us look at this a little closer. That hyacinth bulb, for instance. Why does it develop into a plant? A child might answer, Because God made it to do so; the "great German scientist" might answer, Because it is an "organic complication of force-endowed materials," whose potentiality tends by inherited development to that result. It sounds wonderfully learned, but the scientist's answer, like the child's, means exactly this: it does so because it does. But the child's answer has the advantage of being a humble admission of ignorance, the scientist's is a claim to pretended knowledge—the very worst sort of ignorance.

A great deal of the difficulty surrounding the conception of life is due to our habit of regarding each thing as an isolated individuality. We do the same in physics: in this latter case, however, true science recognises that there is no such thing as an isolated object. Everything everywhere is connected; gravitation binds the universe into one whole, in which every part influences and is influenced by all the rest; light, heat, sound, all the radiant forces are for ever transmitting energy from point to point, so that we may compare the atoms of matter to objects floating in an infinite ocean of energy. Extend the same conception to life, and we may realise that each individual life is not a complete and isolated unit, it is but a cell, a leaf, a flower upon the tree of the infinite life whose streams are the source of its own vitality.

There are four theories of existence which include all the possible doctrines of life.

1. The Lucretian idea of the fortuitous concourse of atoms, drifting endlessly through space, uniting, by mere collision and propinquity, to form the universe.

2. The Gnostic conception of a creative spirit acting on an opposing self-existent matter.

3. The common orthodox notion, very definitely expressed in the Westminster Confession of Faith, "it pleased God . . . . to make *out of nothing*, the world and all things therein."

4. The Vedic doctrine that the infinite, self-contained and all-containing one (implied by their "Om" as also by the "I am" of the Jewish scriptures), "willed to create various beings *out of his own divine substance.*"

It is the first of these which is sustained by such writers as Büchner and other pure materialists who endeavour to convince us that thought, consciousness, and will can arise out of the association and conjoint actions of material atoms having no consciousness or will. This is the school of the purely materialistic evolutionists.

The last is more like that of those evolutionists who recognise the utter incomprehensibility of nature and existence apart from the action of mind and will. They see that the "organic complication of force-endowed materials" of the other schools needs the controlling engineer to make their action conceivable. To them, life, soul, thought are not an incomprehensible product of matter and energy, but an agency superadded to matter and energy, which carries these out of the non-vital domain of physics into the higher order of metaphysics. It is because the so-called science of metaphysics is an attempt to describe and define that which is by its nature beyond our comprehension that it has become a mere wilderness of verbiage.

I had written thus far before the appearance of No. 969, several of the letters in which are thus answered in anticipation. "F. W. H." (21936, p. 150) endeavours to explain Büchner's steam-engine ideas, but his explanation will break down. He says that the meaning is, that "as the engine produces motion, so does the brain produce thought." Even so, that gives no proof that thought is motion. I know that the brain *produces* thought, and must ask "F. W. H." to endeavour to seriously understand what this means in two distinct lines: What is the brain? You see the whole question is begged in comparing it to the steam-engine. We know that by the steam-engine Büchner means the merely physical association of matter and force; but the brain includes the agent about which we are debating, that agent which I have compared to the engineer. But there is a more fundamental distinction: the *steam-engine does not produce motion;* it simply transforms motion. It *produces* nothing; it only directs and applies pre-existing energy to a purpose controlled, as to manner, by the purpose and will of its designer; as to time, by the purpose and will of its engineer—purposes and wills working through, but independent of, the organic complication of materials. But the brain *produces thought*; it possesses a creative power in no way comparable with any action of the steam-engine, or with any material action.

Energy is not matter; energy is not even an action of matter. It appears conceivable only as something impressed upon matter, intelligible only as an effect of will. But energy is conceivable only as manifested in connection with matter. It is motion, and though mathematicians do talk about "pure motion," it seems impossible to conceive of motion except as connected with something moved. Yet we can clearly distinguish between matter and motion, and conceive their separate properties and actions. We can conceive matter *per se*, and apprehend the change in its actions when energy is superadded. But the actions of life involve just such another different set of functions, exerted by combined matter and energy, which it is more reasonable to attribute to a fresh agent than to some latent function of their own which only comes into action in the form which we call life, and which every evidence we have proves cannot come into play spontaneously.

Let us give what functions we may to the ideal matter, we have to explain what sets this function of "life" into operation. We only put the difficulty a little further out of sight by attributing life to a function of matter itself, instead of to some agent as distinct from both matter and energy, while dependent upon both for its manifestation, as energy is from matter. The quotation from Haeckel in like manner begs the question; he says, "Our soul life is indissolubly bound up with the organisation of our central nervous system." He does not know that; by no effort of reason or experiment can he prove it. All that he knows is that his soul life does actually perceive its relations to matter and energy through his nervous system; that they are "indissolubly" united he simply *thinks*, just as all the religious ideas of mankind are based upon the *belief* that they are united only for a time and capable of separate existence. Neither the belief nor the thought can be proved or disproved except by the evidence of the separate existence, and such evidence the nervous system would be incapable of perceiving. The very assumption of the separate soul life implies its being out of the range of mere matter and energy. Once we have entered upon this line of thought it is easy enough to see that animal life and human thought may each be successive stages of existence due to the adding of a new agency to those which constituted the lower.

If proof is asked, none is possible. It is all a matter of reasoning from imperfect evidence. It is simply a question. Can we best account for incomprehensible facts by attributing these effects to distinct agents of which we know nothing but their actions, or to functions of a something which we call matter, but of which we equally know nothing but its actions? When we are told "the soul of the plasticule would therefore be the ultimate factor of the organic soul life," how much have we advanced towards understanding the matter? What is the soul of the plasticule? Does it not come to the same thing as that which the other belief calls "life"? Does not Haeckel himself see this when he says "All organic matter at least, if not matter as a whole, is in a sense gifted with a soul"? The distinction between this and my own statement of the case appears to me very slight. I have never pretended to explain, for instance, how the individual human soul is constituted. I think it probable that it, too, grows out of its proper elements concurrently with the body, which may be, for all I know, the agency of its growth.

"Lamplighter" (21937, p. 150) introduces an entirely distinct thing. Clairvoyance, so-called, has nothing to do with the subject of transfer of thought, except that clairvoyance is probably only a misconceived effect of transfer of thought; at all events, I have always found it to be so. No one professes experiments on the transfer to be of any *use* except as enlightening us upon the nature of thought and existence. But that is a matter of supreme importance.

When Mr. Craven (21938) has anything to say that he appears to understand, or wants information to enable him to understand anything, I shall be glad to listen to or help him. But he must excuse my paying no attention to such remarks as he is in the habit of making on these subjects. Sigma.

LIFE AND M

[21960.]—I am quite of
almost enough has been

may prevail. It is
to call the conclusi
other scientists of
and illogical";
aspersed, but pos
is stranger than
when it knock
ideas and p
"Sigma"

"entity," but I must demur to his statement that he said nothing as to the nature of thought or mind. It is on record in your valuable journal that "Sigma" calls "mind" an entity, who works with the senses like a workman with his tools, and I must really be excused if I took that to be an explanation of the "nature" of mind.

"Sigma" is acquainted with electricity; now, if he composes a "battery" of certain elements placed together under certain conditions, does not here "mere matter" produce a "force"? Will he call this "force" an "entity" or agent working with the "elements"? Remove the necessary conditions or displace the elements, electricity disappears or ceases to act. Is it unreasonable to suppose or conclude that mind or thought is a similar "force" or "energy" resulting from the action of living brain, perhaps by the assistance of electricity under the necessary conditions, which also disappears if brain matter is destroyed or the conditions altered? Does not a piece of wire (mere matter) with the assistance of an electric current become capable of transmitting the human voice a thousand miles?

Büchner says, "Force and Matter," page 187: "Electric currents constantly surround the nerves when at rest. These currents cease, or become weaker, whenever the nerve is excited to activity. The nerves, therefore, are not the conductors but the generators of electricity. This generation ceases with the activity of the nerves, that is, with sensation or the exertion of will. Psychical activity accordingly was, by some, defined as latent electricity, and sleep as a relaxed function of the electrical nerves! Experimental inquiry may, perhaps, lead us to a more intimate knowledge of psychical functions."

Nothing is ever gained by pronouncing a mere "non possumus," by saying this "must" ever be unknown! In that way all act of inquiry for "truth" has always been opposed.

The wisest and best authorities may be entitled to our greatest respect, whether ancient or modern; but let us also not forget that some of the wisest and best are known as such "now" only to their posterity, and that Galileo was made to recant on the rack his opinion that the earth moved, "by the wisest" and best of holy Inquisitions!

F. W. H.

[21961.]—In letter 21934, "Anglo-Dane," after speaking of cell-divisions, makes the following statement:—"I am fully aware of what forces are in operation during the growth of the cell. I am certain we can produce artificially all the conditions of matter and force which are present and active in the growing of the cell." The calm assumption of knowledge is astonishing to anyone who knows anything of the subject. As a chemist and a physiologist, I would caution readers of the "E.M." against accepting such an assertion as at all expressing the views of scientific men. At present the chemical composition and structure of living protoplasm cannot be ascertained. We know that certain substances (albumens, salts, &c.) can be extracted from dead protoplasm, and certain empirical formulæ have been proposed as representing the ultimate composition of dead protoplasm; but of the arrangement of the atoms of the different elements nothing is known. Those who know how wonderfully the properties of a substance are altered by changing, even slightly, its atomic arrangement without altering its composition, will see how far at present the physiologist is from a knowledge of the chemistry of life.

With regard to the forces actually at work as little is known. For example, the unicellular organism, the amœba, requires oxygen for the performance of its functions, and there is no doubt that it eliminates carbon dioxide, so that it is an animal; or, in other words, there is a running down of energy. But what particular form of force the energy, produced by the combustion of the carbon of its tissue, takes, it is impossible to say. We may assume that the ultimate form is heat; but it is the intermediate form, or forms, that it is important to determine.

With regard to the second sentence above quoted, it must be obvious to all that if we are so great a distance from the comprehension of the constitution and forces of living matter, we cannot be in a position either to artificially imitate them, or to predict or deny the possibility of their imitation in the future.

E. F. H.

TRANSFER OF THOUGHT.

—Since the discussion has turned aside to
bject of the nature of thought "Sigma"
fortunate. The wide gaps in his
noticeable, as in the earlier
he argued with a clear
with facts, and held

ling light on the
109, where he
and mind
"what

known (p. 39), and he has already spoken of the existence of this extra-material principle as a "truth" (p. 39), and a "fact" (p. 66).

Now the only possible inference is a startling one, viz., that here is a fact and a truth that are not within the domain of science, nay, more, that this fact and this truth are not to "be known." In what way are we to describe, how can we characterise, a fact and a truth which are unknown? Of course, there may be facts and truths which are not now, and will be never known; but who then will say that they are facts and truths, and if anyone will foolishly venture to say so, what possible evidence can he offer as to facts and truths unknown and unknowable to enable us to judge whether they really are facts and truths? Then there seems to be no escape from the conclusion that "Sigma" is entirely ignorant of this fact and truth, and that therefore he is one of those "people who talk about what they know nothing about" (p. 29), and "asserts as a fact what is nothing but a notion based upon his own presumption and ignorance" (p. 66).

Science is what we know, and as there can be no fact recognised as such until it is known, science includes all facts, and immediately a supposed fact appears it is the special province of science to investigate and determine whether it is indeed a fact, and can be added to our sum of knowledge. This is what science has to do with the matter. If, though, science, as "Sigma" defines it, has nothing to do with the question, then the question relates merely to a notion, a speculative exercise of the imagination, and to no fact. To hold an opinion about what is, according to "Sigma," unknown and unknowable, surely is sublimely ridiculous.

"Sigma" is only just when he says (p. 39), "it is like the presumptuousness of children when the anatomist denies the existence of some higher principle." All that the anatomist can fairly say is that there is no ascertained fact, no known course of reasoning, no available evidence, which points to the existence of any principle other than may be involved in the existence of matter.

According to Moleschott, thought is a motion of matter. "Sigma" replies to this by accusing Moleschott of presumption and ignorance. He admits, however, that thought is accompanied by certain motions of matter, seemingly as heat is. Then it is certain that there is a causal connection, and either thought and heat are causes of motions of matter, or certain motions of matter cause the phenomena of heat and thought. When we see that certain phenomena and certain motions of matter are contemporaneous, what do we decide—that the phenomena cause the motions, or that the motions cause the phenomena?

W. A. L.

MATTER AND THOUGHT.

[21963.]—When one hears that vital force is a nonentity and that the brain thinks, one cannot help asking, if this be so, what, then, is the cause of the wonderful difference we know so well to exist between the living and the dead? Again, if thought is due to the motion of brain matter, what kind of motion is it? Motion cannot entirely cease in the brain at death—the chemical forces must prevent that from being the case. Is the motion so induced thought? If not, what constitutes it? But why should I conclude that the motion of matter within the brain is thought, any more than the matter in motion without the brain which conveys the ideas of one speaker to another is thought? In a vacuum there could be no transfer, and apart from a material organisation, no manifested thought. It has always appeared to me that the law of the conservation of energy is fatal to a materialistic explanation of thought. It may be supposed that this law holds good of the physics of the brain as elsewhere, and when the physical equations are satisfied, there is no energy left to convert into thought. It is motion plus thought. Instead of saying that thought is the result of matter in motion, it is far more tenable to say that thought *is* matter in motion. But is this materialism? Why, it abolishes matter by converting it into mind—all physical facts are mental facts. We are landed in idealism pure and simple.

It is generally admitted that idealism cannot be proved to be false; but if we are to hold by common sense, which idealism dispenses with, and to retain the notion of matter at all, we are attributing to it a property which we do not know to belong to it. What we do know is, that mind is associated with a particular kind of matter only for a time, and that the connection, once broken, can never be re-established.

Mind is so opposed to matter in all respects, that we should require good proof indeed of its not being something *ab extra*.

J. A.

THOUGHT READING AND GIRL'S LOVE OF ADMIRATION.

[21964.]—I am a young Irish girl, just sweet *16, and I beg* leave to protest most emphatically *against the assertion of "F.R.A.S," who, in letter* 21898, page 25, says "the love of approbation and admiration is so innate in all girls that they will do anything to win it." There is at least *innate* evidence in this paragraph that your great scientist knows nothing at all about girls. I am sure he is a cross, crazy, pre-occupied *fellow*, who is for ever impaling spiders on his microscope and mooning through his big telescope—an implacable old grey-bearded astrological wizard, who knows far more about the horrid old woman rolled up in a blanket than he does of a dear, sweet, darling little girl dressed in inimitable fashion, and wearing the "latest thing" in sealskin hats. I can tell "F.R.A.S." that no girl, young or old, would act those deceitful things. Who ever heard of a *girl* going on the stage at the invitation of any conjuror or mesmerist, sticking the leg of a chair into her mouth, flapping her elbows, or capering around the stage, trying to make us believe she felt herself bewitched into a Highland piper? These and other follies she leaves to "F.R.A.S.'s" boys, whether gutter snipes or nobles. I will not here say what a girl can do besides dressing to win admiration; but I will tell "F.R.A.S.," until he leaves the cold, distant, stars of heaven to consider the near, warm stars of earth, he shall have no admiration from me. As for reading a young girl's thoughts, "Sigma," "F.R.A.S.," or any other man may rest assured that is all moonshine!

A Limerick Girl.

SECOND SIGHT AND TRANSFER OF THOUGHT.

[21965.]—While the subject of transfer of thought is "to the fore," I should be much obliged if you, Sir, would spare me space for a question or two on the above-named subject. I should much like to hear "Sigma's" opinion of the phenomenon called by the Highlanders *Taishitaraugh*, or second sight, which consists, I believe, in the faculty of perceiving persons engaged in actions either future or taking place at the time, but unknown to the person witnessing them. Were I to ask for instances, I have no doubt your readers could fill me a whole No. of the "E. M." with what they have *heard or read*; but can any of them tell us anything as satisfactory as "Sigma's statements regarding transfer of thought. He says simply, "I have done it." Can any among your countless readers state *that they themselves have seen* any unaccountable appearances (for want of a better term), whether confirmed by subsequent events or not? It seems to me that the faculty must have some kind of connection with transfer of thought, if such faculty exist; but first let us have some proof of its existence.

Charlie.

EXTRAORDINARY MESMERIC SLEEP.

[21966.]—Knowing that, in the interest of science, the "E.M." is always happy to insert general information for the benefit of its numerous readers, I have taken the liberty to inform "Sigma" and others that, having heard of a case of very prolonged sleep, I, last Friday, left Edinburgh on a visit to the Glasgow Western Infirmary to see the patient, and have had that satisfaction. By Dr. Cameron, who (under Dr. Gardiner) has charge of the case, I was very courteously and kindly received, for which I thus publicly thank him. Dr. Cameron gave me the Ward Journal to read up the case, at same time informing me that the patient is a Highland woman from the Island of Skye; that she is married and has three children; that her name is Mrs. McInnes; that she is 35 years of age, and has been for over 18 *weeks* in *one continuous sound sleep*, from which she has *never once wakened*. In this state she lies on her back and never moves a muscle. Her pulse is 80, her breathing fair, and, to keep up her strength, is fed three times every day by means of the stomach-pump apparatus. Now, however others may reason or speculate on this extraordinary phase or phenomenon of suspended power, to me it is a singularly clear case of true *natural* trance, usually called *deep mesmeric sleep*. My explanation of it is that, from some *requirement* of the animal economy, the patient yielded obedience to the *call to sleep*; that, *conditions being favourable*, the *tendency to continue the rest prolonged* the period of ordinary waking; that the over-solicitude of friends *interfered* with the natural sympathies of the system *to recover itself*; and that this *outside* pressure on an extremely sensitive, high-pressed nervous system, very likely brought about by well-meant but ignorant tampering with delicate bearings, produced an *outrage* of the great *natural* law of toleration, which ended in the breaking of the balance between the sensory and motory nerves. From suggestions which are being acted on, there is some hope of nature recovering herself. Meantime, the lesson is suggestive enough of many things; and, although "one swallow does not make a summer," it appears to me that *one fact* of this kind is worth more to *science* than a shipload of arguments would be against it. **J. D. Morrison**, Surgeon-Dentist.

27, Grange-road, Edinburgh, Oct. 17.

THE PANAMA CANAL.

[21967.]—The only comment necessary on letter 21952, p. 155, is, May the Editor and his readers live until the Atlantic and the Pacific break through the isthmus! Tithonus, however, reminds me that it is to be hoped they won't grow any older, for if they do, how terribly old they'll be! It may interest your readers to learn that M. Dingler, the chief engineer, is convinced that locks will be necessary for the following reason:—At Colon, on the Atlantic, the difference between high and low-water mark is not more than 58 centimetres (23in.), whereas at Panama, on the Pacific the average variation in the height of the water is 4 metres (13ft. 3in.), and is sometimes as much as 6 metres (19ft. 8in.) Moreover, high water at Colon is about nine hours later than at Panama, therefore half tide at the one place corresponds with the flood or the ebb at the other, and there may be a difference of tide level between the ends of the canal equal to half the rise on the Pacific coast. By comparison with the canals and rivers which empty themselves into the Bay of Biscay, M. Dingler estimates that the speed of the current would be from five to six miles an hour in the uninterrupted portions of the channel, and greater when the cross section is reduced by the passage of a vessel. It would, therefore, be impossible to use the canal in one direction, and very dangerous to do so in the other, so he concludes that to enable vessels to enter and leave the canal at all states of the tide it would be necessary to build locks at the Panama end, and he proposes to establish there, one for entrance, one for exit, and the third to be used when either of the former are under repair. If the locks be not made, it will be necessary to slope the bed of the canal from Colon to Panama, cutting it two metres deeper at the latter end, and this would require the removal of 10,000,000 cubic metres of soil, at a cost of 45,000,000 francs. The lock would cost 11,500,000 francs, and thus by their employment, a saving of 32,500,000 francs would be effected.

Besides the reasons pointed out by "Sigma," p. 15, there need therefore be no fear of the Gulf Stream wasting even a portion of its strength on the Pacific.

Nun. Dor.

CONTINUOUS BRAKES.

[21968.]—Seeing in last Friday's "E. M." a letter by "Imprimatur" on the Parker-Smith screw brake, I should like to say a word or two with regard to his letter. He remarks, with reference to the Westinghouse brake, that fatal accidents have occurred owing to the brake applying itself automatically. Why he says this I cannot understand, seeing that the Parker-Smith brake is itself automatic. "Imprimatur" is wrong in saying that to release the Westinghouse brake, after it has applied itself automatically, takes 10 to 15 minutes. I have seen it done on the North Eastern Railway in *less than three minutes*—a very different matter. Again, if a fatal accident occurs owing to the above cause, it is the fault of the signalling department, and not of the continuous brake in use. It is far better that the brake applies itself automatically than that it gives no indication of a failure, so that when the brake is urgently needed there is no brake power available. Again, the chain connection is not so good as "Imprimatur" thinks. The chain connections often break; indeed, I have often seen trains on the L. and N.W.R. running, with the broken portions of the chain rattling about in the four-foot.

If the brake-blocks of the Parker-Smith brakes are normally on, does not this impede shunting operations, when carriages are uncoupled? And, granting that there is an arrangement for preventing any delay arising from this cause, by which the brake-blocks can be *kept off* the wheels, will not this arrangement interfere with "Imprimatur's" practical test that the brake is in proper working order when the train starts? By this I mean that, supposing a train has been made-up and shunted down to the platform ready for starting, in these shunting operations this arrangement will have to be used. It can, therefore, easily happen that the shunters forget to restore the brake to its normal position, and if all the chains are not connected, the train may start with only a portion of the brake-power available. In this case the driver cannot tell that anything is wrong, because the brakes will *not* go on. "Imprimatur" gives the parallel case of the Westinghouse, in which the taps between the carriages remained unopened. But the rear guard, by looking at the gauge fixed in his van, can easily see if the train-pipe is completely charged with air or not.

But "Imprimatur" has forgotton one of the most important characteristics of a good brake—viz., the brake-power. The P.S. brake is applied by the slackening of the connecting chain, which allows weighted levers to fall, and thus the brake-blocks are forced against the wheels. I very much doubt whether the falling of a weight can produce enough brake-block pressure (30,000lb.) To produce any considerable amount of pressure, the weights must be exceedingly heavy, and have a very large leverage.

This is a serious defect in mechanical brakes—viz., that pressure enough cannot be produced. Another serious defect—as experienced both in England and on the Continent—is that the brake connections (whether rod, screw, or chain) are liable to be clogged up with dirt and dust, and frozen up in winter.

I should like to see the results of a trial of this brake on a train of from 15 to 20 carriages, and until it has proved itself thoroughly satisfactory in such a trial, its merits must not be compared with those of a brake which has stood thoroughly practical tests. Let "Imprimatur" remember that he is advocating an untried brake, and also let him remember that simplicity is not always a merit. I agree with him in hoping that Mr. Parker-Smith will give us a description of the brake, with drawings, stating how he attains the necessary qualities belonging to a good continuous brake. In conclusion, I add that I am a totally impartial observer of the brake question, and only wish for the best appliances for insuring safety on our railways.

Oct. 18th. **Meteor.**

CONTINUOUS BRAKES — THE ACCIDENTS AT PERTH, CARLISLE, AND LOFTHOUSE.

[21969.]—Major Marindin's report upon the collision which occurred at Perth on the 28th July has been published, and contains some important information. An East Coast train from Edinburgh was standing at the ticket platform, Perth, when it was run into by a West Coast Express from Euston; this latter train was composed of West Coast vehicles (the joint property of the L. and N.W. and Caledonian Railway Companies), and was fitted with the Clarke and Webb chain-brake of the newest pattern. This brake is *supposed* to be under the control of the driver by means of the cord; we know that drivers have many times stated that they could not get the brake to take effect; but the true state of the case has not before been officially brought to light.

Major Marindin made some practical experiments with a train made up exactly like the one in question, with the identical brake-van. He reports:—"It is an absurdity to talk of a patent chain brake at the rear section of a train of ten vehicles being under the control of a driver by means of the connecting cord, if by control is meant the power of applying the brake. The utmost a driver can do, even with the assistance of his fireman, is to pull the lever about 7½in. up the quadrant, which is not sufficient to cause the brake-block to rub against the wheels." He also states: "Such a machine is nothing but a trap; and following so soon after the terrible disaster at Lockerbie, hopes it will cause the Caledonian Railway Company to insist upon having the West Coast Joint Stock fitted with the brake which they have adopted."

The above statement of the danger of the chain brake is very clear, and must make every one feel more and more the injustice done to poor driver McCulloch, who was actually sentenced to four months' imprisonment because he could not apply the emergency chain brake at Rutherglen. It is satisfactory to find that the Caledonian Company has "insisted" on the West-Coast Joint Stock being fitted with the Westinghouse Automatic Brake, and now the Great North of Scotland Line has adopted the same system, there will be no further trouble with regard to interchangeability of rolling stock in Scotland, especially as the Midland Scotch Joint Stock has always had this brake; the East Coast has the connecting pipes, and the West Coast is now being fitted with the brake, some of the carriages being already in daily working.

Major Marindin also presents his report upon a collision which took place at Carlisle on the Citadel Station Joint Committee Line. On the 13th August, a return North-Eastern excursion train, drawn by a London and North-Western engine, came into collision with a light engine. The report concludes:—

"The accident might easily have been prevented if the driver of the excursion train had had a continuous brake at his command; but, as is too frequently the case, owing to the various classes of brakes in use upon different lines, the Westinghouse brake with which the carriages were fitted was useless so long as the train was drawn by a London and North-Western engine. It will sooner or later become a question for very serious consideration, whether stock should be allowed to be transferred from one line to another unless means are provided for utilising the brakes with which it is fitted, and which are necessary for the safety of the passengers."

The collision which occurred at Lofthouse Station on the Great Northern Railway, on the 15th September, is another instance of the danger which follows the use of slowly-acting non-automatic vacuum brakes. Here was a short passenger train consisting of only engine, tender, and seven vehicles running at twenty to twenty-five miles an hour, up a gradient of 1 in 100, yet all the vacuum continuous brake could do was to reduce the speed to about fifteen miles an hour in forty to fifty yards. If this train had been fitted with an efficient brake, the collision might have been rendered harmless, or, perhaps, entirely avoided. The moment the collision took place the Smith's vacuum pipes were broken and the brake rendered useless, and passengers have informed me they were more injured by the "sharp recoil" of the carriages than by the actual collision. It must be remembered that with an automatic brake no recoil can occur, thus preventing this cause of danger to the passenger.

Clement E. Stretton.

40, Saxe-Coburg-street, Leicester, October 20th.

RAILWAY SPEEDS.

[21970.]—I have been waiting patiently now for some months, hoping that some "Railway" correspondent would kindly favour the readers of the English Mechanic with particulars of the Duke of Edinburgh's "special" from Leeds to London, mentioned briefly by "C.R.M." in No. 935 of the "E.M." (p. 571) as having done the distance in exactly three hours. If this statement be correct, this is the best run on record on either Broad or Narrow gauge, and details of the performance would be most interesting.

By the way, I had a splendid run on the G.N.R. on the 4th of this month in the train due to leave Peterboro' 1.38, and arriving at King's Cross 3.15. The train was late, and did not leave Peterboro' until 2.2, and arrived at Finsbury 3.25. The engine was No. 92 (Doncaster, 1870), 7ft. 6in. single, cylinders 17½ by 24, with inside bearings to driving, and outside to leading and trailing wheels.

The train consisted of 10 or 12 carriages, I forget which. I give a list of speeds taken, but was most occupied in checking individual miles:—

	10¼	miles in	15	minutes	= 41	m. per hour.
	15	,,	15	,,	= 60	,, ,,
	7¾	,,	8	,,	= 58⅛	,, ,,
	9	,,	10	,,	= 54	,, ,,
	8	,,	10½	,,	= 45$\frac{5}{7}$	,, ,,
	23¾	,,	24½	,,	= 58$\frac{8}{49}$	,, ,,
Total	73¾	,,	83	,,	= 53$\frac{3}{10}$	,, ,,

The speed for individual miles was frequently 65½ miles per hour, and on one occasion at least reached 72 miles per hour, the last few miles being done very fast indeed.

October 20th, 1882. **St. Aubyns.**

THE NEW STANDARD WIRE GAUGE.

[21971.]—I send you inclosed a copy of the decimal equivalents in parts of an inch of the new legal standard wire gauge, also in line with them the decimal numbers approximating to the old Birmingham wire gauge (B.W.G.).

The new gauge runs very nearly with the present Lancashire wire gauge, and if adopted, the old B.W.G. will be "a thing of the past."

Descriptive Number B.W.G. No.	Equivalent in parts of an inch.	Old B.W.G.
7/0	·500	·500
6/0	·464	·465
5/0	·432	·430
4/0	·400	·400
3/0	·372	·375
2/0	·348	·350
0	·324	·325
1	·300	·300
2	·276	·275
3	·252	·250
4	·232	·230

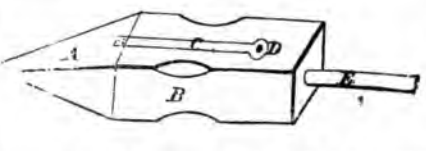
Lestar.

AN IMPROVEMENT IN SOLDERING-IRONS.

[21972.]—As I am often troubled with soldering-irons being overheated, and the solder perishing in consequence, I made a copper cap (well tinned) which could be taken off when the iron required heating. Finding this contrivance answer exceedingly well, I thought the information would be useful to other amateurs who are troubled in the manner I have intimated. The following is a rough sketch of the iron, with the cap attached thereto. A is the cap; C is a strip of copper riveted on to cap; D is a hole in the strip, with hole in the iron corresponding; these to be fastened together with a pin, which can easily be removed when the iron requires heating. B is the iron; E handle.



Arthur R. Hallett.

Sturminster Newton, Oct. 15th.

MANDREL SCREWS.

[21973.]—I notice that your correspondent, E. R. Dale, in No. 968, requests the criticism of your readers on the mandrel screw figured by him. I will say, in my opinion, that it is the most sensible mandrel screw I have seen described in your columns for some time. The smooth cylinder at the left end of the screw I think is a decided, I do not say, improvement, but an absolute necessity. My own lathe mandrel has just such a one, and it is made by a first-rate London maker. In the drawing, however, the right end of the screw should be rounded off, and not cut square off as drawn. The cylindrical projection marked B, I think, would be very much in the way, and would afford no advantage whatever. I myself consider that Dr. Edmunds's thread of 10 to the inch altogether too fine, unless for a mere ornamental lathe, and that is a part of turning I have never had anything to do with. I think myself that you cannot improve upon the Whitworth thread of 8 to the inch for the mandrel screw, and I would make it for a 5in. lathe 1⅛in. in diameter.

Your very interesting correspondent, Mr. Evans, had several lathes at the exhibition at Islington in July last, and I particularly noticed a very nicely-made plain lathe, but with the mandrel screw 10 to the inch; and I am certain it is decidedly too fine for everyday use. One screw figured in your journal had the screw scooped out at the extreme left of it, thus making it weaker there than anywhere else, instead of stronger, which it of course should be.

C. A. T.

STYLOGRAPHS AND THEIR DEFECTS.

[21974.]—The stylographic pen is a great convenience; but no inventor seems to have succeeded thus far in making a joint which will prevent soiling the fingers with ink. A remedy for this leakage, which has been tried and thus far seems to be complete, is to rub the joint on which the fingers rest with the thin end of a piece of wax. Hold the pen over a candle, lamp, or the flame of a match, till the wax melts, when it will bite the lute so that no ink can escape through it.

Washington, D.C., Oct. 9. **M. C. M.**

THE BERTHON POWER GAUGE—CORRECTION.

[21975.]—Allow me to correct a numerical error in my letter, No. 21951, as it appears in your issue of to-day. The third measure in the column headed Gauge A corresponding to ·062 and ·014 in the other columns should be ·020, not ·120 as printed.

T. Perkins, M.A.

Shaftesbury, October 19.

REFLECTION OF LIGHT.

[21976.]—I should be glad of a few remarks from "F.R.A.S.," or other competent correspondent, on the following quotation from Tyndall on "Light":—

"The light which falls upon a body is divide
into two portions, one of which is reflected fr
the surface of the body, *and this is of the same*
as the incident light. Solar light reflected
surface of even a black body is whi
camphine smoke in a dark roo
sunbeam passes renders t
white by the light scattered
the soot particles."

Tyndall also says of
covered with the black
be white.

He then speaks of
entering some dista

being there robbed of some of its constituents, and re-emitted more or less changed in colour.

My difficulty is this: Is not this *second* portion that which is usually called scattered, or are there in fact *three* kinds of reflection?

1. Regular reflection according to the equal-angle law in general; no colour change.
2. Surface scattering in all directions; no colour change.
3. Partial absorption and re-emission in all directions with the so-called colour of the body.

Surely when Tyndall speaks of the moon as white by means of the first portion of light, he cannot refer to specular reflection. In fine, why is the moon white: if the moon were cased in red annel, what then? **L. S.**

LEGAL REPLIES.

[21977.] — Restraint of Trade — Covenant (51854).—This extract from the deed does not say whether there was any limit as to space, such as that the vendor should not carry on the said business within ten or a hundred miles. If there was no limit at all, then the covenant may not be binding; if there is a limit of space then the querist can manufacture beyond that limit. Presuming nothing is said about space, it would not do for the querist to carry on business so close to his old place, for he would probably be stopped by an injunction, and be sued for damages; supposing, of course, that the covenant is held valid under the circumstances. But if he went ten or twenty miles away, I should think he could sell his inventions as he proposes.

Married Women's Property—New Act—Title Accruing (52935).—This question raises the same point as was lately discussed in these columns between "Lex" and myself. Section 5 of the Act of 1882 gives to a married woman who was married before the 1st January, 1883, such property as that in which her title to it shall accrue after that date, and whether it be vested contingent or in remainder. In this case the title of M. to the legacy left her by S. accrued in 1837, when M. died. The legacy then vested, as we call it, in M., the legatee, although it was not to be paid until the death of the testator's husband. Under these circumstances I think M. does not take the legacy as her separate property under the Act of 1883; but that it will go to her husband when he reduces it into possession.

Right of Entrance and Way—Non-User (52020).—Non-user in a right of way, or any other easement, would not, alone, be conclusive evidence of its abandonment. But it is some evidence, and coupled with other facts it would help to support a defence that the right of way formerly possessed had been abandoned, and so lost. Non-user of a right of way for twenty years would certainly raise a very strong presumption that the right had been released; but so long a time is not in all cases necessary to arrive at the same result, and much must depend on the facts. As this querist has another entrance, his not using the one in question would not prove he meant to abandon it; at all events until after the lapse of a long time, which may be broadly put at 20 years.

Apprentice's Overtime (52023).—The indentures of apprenticeship should say what hours of work are to be required. The fact of a task being done would not enable an apprentice to do nothing more. If by overtime the querist means beyond the hours agreed upon, then the apprentice could not be compelled to work longer. Should nothing be said about hours in the indentures, then the apprentices must abide by the rules of the trade. The real question here seems to be rather the rate of wages than the hours of work.

Apprentices and Housework (52040).—An apprentice bound to a trade cannot be compelled by his master to do housework. His duties are limited by his indentures, and by the needs of the trade in which he is bound. An apprentice must obey his master, but is under no obedience to his master's wife. He can simply refuse to obey her orders, and leave his master to enforce such obedience if he can.

Fred. Wetherfield, Solicitor.
2, Gresham-buildings, Guildhall, E.C.

HYDRAULIC RAMS WITH TWO PULSE VALVES.

[21978.]—With regard to "Glatton's" reply, letter 21908, I am glad to find that he has thought over the true meaning of "expend"; had he done so before, it would have precluded the necessity of so much correspondence. Such misreading of words often causes a great deal of trouble, and with regard to the double pulse valve I beg to differ greatly from "Glatton," as to the time of its use and situation. **P. J. Davies.**

[21979.]—The error into which Mr. Davies has fallen is, I think, in not considering that although there is a greater mass of water in a long trunk than in a short one, with same head, still in the long trunk ram more water will run to waste at the foot-valve between two successive beats, in order to produce the velocity necessary to close the valve. It is exactly the same as with a body on an inclined plane; the body must run a greater distance down a flat incline than down a steep one, in order to produce the same velocity. It is utterly impossible by merely increasing the horizontal length of the trunk to obtain more water from a ram; in fact, it is more likely that less water would be sent up in consequence of extra friction, and therefore the ram would be less efficient and more costly.

J. W. C. A.

ELECTRICAL LAUNCHES.

[21980.]—I quite agree with your correspondent Mr. Conry, that if electrical launches are to be brought into immediate use, the electrical energy must be obtained from primary batteries. Although the accumulator possesses every advantage in space, weight, and rate of discharge, over a primary cell, it is of no practical use until charging stations are erected, which from the present aspect of the "financial-electrical" horizon, is very far distant indeed.

The best and most efficient cell for such a purpose is undoubtedly a Bunsen; but the objectionable fumes of nitric acid, and the destructive nature of that fluid when in contact with the hull of the boat, or the clothes of the passengers, are serious disadvantages.

The bichromate cell, as used by M. Trouvé in his experiments has a single fluid, and therefore is more compact in form, but a comparison of the efficiency of such a cell with that of a corresponding Bunsen results in a verdict in favour of the latter, despite all its faults.

We still lack a *good* primary battery for motive power and domestic lighting. No doubt one will be discovered in the future that will, for simplicity, efficiency, and cheapness, eclipse all that are within the range of our present knowledge. Still there is no reason why, pending the invention of this cell, we should allow the application of electrical power to small vessels to lie dormant, since the disadvantages of the primary batteries we have at our disposal are not so great as to render them impracticable for the purpose.

The fumes of the Bunsen cell may, with judicious manipulations, be so greatly reduced as to be hardly discerned, and the danger of spilling the acids minimised so as to render boat and clothes safe from corrosion. In fact the whole cell may be modified; the nitric acid used may be less than half the quantity that is usually consumed, while the efficiency of the battery is unimpaired.

Mr. Toynbee has partially proved, by his experiments, that the consumption of zinc is not large, though I do not agree with his system of *diluting* the nitric acid, this process being unfortunately entirely automatic, and the result obtained rather too soon.

Mr. Conry asserts that he has not yet met with a motor that is fairly efficient. It is probable that he has not; still there are excellent motors in existence, giving from 80 to 88 per cent. of the electrical energy of the battery to the shaft. The only method of indicating the actual power of an electromotor is by dynamometer upon the shaft, and the result divided by the battery power gives the efficiency of the motor. Hence an electromotor compares favourably with the steam-engine, for the latter cannot utilise so much of the energy given out by the burning fuel as the electromotor does of the consumed zinc, and by measuring the actual power of a steam-engine in the same manner as an electromotor, and comparing the result with the indicated H.P., it will at once be seen that the loss between piston and crank shaft is considerable. When comparing the weight and efficiency of electromotors and steam-engines, this method of measurement ought to be employed to obtain accurate results. In fitting a launch with an electromotor, if the proper proportions of the vessel, propeller and motor be calculated, and with reference to the speed at which the motor performs most work while absorbing least current, there is but little difficulty in arranging a battery to produce the electrical energy necessary for performing the work required, with but a small percentage of waste; but this will never be attained by a slow rate of speed.

It is at present impossible to go from Sheerness to Oxford and back in an electrical launch, driven by accumulators, because there are no facilities for re-charging; but directly a few small pleasure boats electrically propelled by means of primary batteries are running upon the river, there will be hardly a boathouse without a supply of necessary chemicals, and until then, the enterprising experimenter in electrical navigation need not curtail his voyages, but rest secure in the knowledge that there are few English towns that do not possess a chemist's shop, and few chemists who do not include in their stock a few Winchesters of sulphuric and nitric acids.

Such a method of propelling launches is quite practicable, and will be successful when those who are experimenting in this direction are aware that a high speed and a propeller to suit that speed are necessary to obtain the most economical results.

Frederick Walker.

3, St. Loys-road, Bruce-grove, N.
Oct. 20th, 1883.

ELECTRIC ELEMENTS.

[21981.]—"Voltametre" wishes me to give some authority for the statements made in my former reply to him. As he quotes Mr. Gordon's work on electricity, those whose researches are given in it will perhaps be sufficient. In Ohm's Laws he will find the passing of electricity is assumed to be similar to the passing of heat through a conducting body—that is to say, as a single and not a dual agent, as "Voltametre" supposes in his first letter.

In the Vol. I. p. 26 which he refers me to he will find that the potential of the earth is taken as zero. Now, positive and negative are convertible terms, and have been used conventionally to the present time as regards electricity; but when a current passes between a body of positive and a body of negative potential, one or the other must be above or below the zero of the earth, according to the definition of "current" from Mr. Gordon's book given in "Voltametre's" last letter. The potential above that of the earth is supposed to be negative electricity, as commonly understood. The proof of this supposition will require further research. If you turn to p. 203 of the volume before mentioned you will find the production of the voltaic current described. Mr. Gordon, however, does not explain the appearance of hydrogen on the copper plate of the battery. On the true positive and negative theory, it is only a result of the chemical action of the current in its progress from the zinc through the connecting wire and copper plate, and so through the liquid to the zinc. An equal current from any source of electricity would give the same effect if it passed in the same direction.

The account of phenomena which seems most conclusive commences in Vol. II. p. 112 of Mr. Gordon's work, where Mr. Crookes' experiments on radiant matter are described. In these experiments the negative terminal gives the active force; the other one has no effect apparently. We can, therefore, assume that the negative potential is above that of the earth, and ought to be marked with the sign + instead of −, as is customary.

"Voltametre" will find that what he has objected to as being loose phraseology is a term of vital importance in the science of electricity, for when the true direction of the current has been established it will be a great step in advance.

J. Sutcliffe.

SCREWS.

[21982.]—I thank "J. K. P." I never did use a tap as a reamer but once, and shall not again, however much the long, taper, full-threaded tempters invite me. What advantages have these taps? I see few.

I was using Martin's table, and thought the holes given small, especially as some squeezing-up usually takes place, which would oblige the taps to ream out some stuff; and so looking into the table I found the sizes very near the theoretical, too near, as I thought, though taken to the nearest 64th only; and in one case a size even less than the theoretical was given—namely, the $\frac{7}{16}$, which "J. K. P." gives as $\frac{23}{64}$, and not $\frac{11}{32}$, as Martin does; and there is a similar instance in "J. K. P.'s" table: $\frac{29}{64}$, though nearer correct than $\frac{30}{64}$, is also under theoretical size. Martin gives $\frac{30}{64}$.

Now I apologise to "J. K. P." for mentioning this, seeing his table was not to be microscopically examined: but I do it to lead to my next question. Is it desirable to use holes so near the theoretical size, even for soft metals; or does "J. K. P." recommend them because common drills usually drill large.

Having broken a tap or two over cast iron, I drew up a table for myself, "omitting the rounded portion," as directed. I was anxious to verify it; the column taken from "J. K. P.'s" drills is so close to the calculated one, that I feel he must have weighed his words well; it is an additional proof that we may rely implicitly on his advice, if we wanted one.

The trick of grinding a drill point out of centre (so as to drill large) was told me by a friend of mine—a good working mechanic; the use of such to undercut (if I understand rightly) a hole for tapping solid steel is new to me. I have not yet tried it, but it looks very 'cute.

In what respect is the American thread better, or worse, than Whitworth? It seems a pity to have both. I can see that a rounded thread of 55° is perhaps harder to originate and verify than 60° truncated, though better for dies and chasers; but is there anything else one way or the other?

Are tools of 90° angle commonly kept in stock? Or is the use or necessity for them and angles finer than 55° so restricted that standards are undesirable? I can fancy that, even for dividing purposes, the angle should vary with the material, to get the best results.

As to the new model mandrel, I am sure the fitting of chucks would be harder than before. Next, while the cylindrical portion strengthens the base by doing away with the groove, yet if it is to have any decent effect in keeping the axis of chuck in a line with that of the mandrel, it should be at the top, not base, and then, perhaps, with a conical shoulder chucks might be made interchangeable. The thread would have to be a loose fit, I fancy, in most men's work; the fitting would be difficult, and it does seem a pity to lose the steadiness the extended surface of a screw gives, all (as it were) a double spiral conical shoulder, the chuck wedging itself firm between the two.

"G. C. C." has drawn a Holtzapffel nose with no groove; of course this is not fair if they all have them. With a broad shoulder they need not, but the groove practically increases the breadth of the shoulder, and that is a consideration in the case of back centre, light running mandrels, whose bearings need to be kept small.

I note another correspondent has mentioned that the cylinder is in the wrong place, but as my letter was written a fortnight back I leave it. I don't value the idea greatly though.

I meant to have asked "O. V." why he considers the slide rest hanging on the front of the lathe to be so well designed to resist the strain of the cut. It seems to me to be far less stiff than the old. What does "J. K. P" say? I suppose either form, though, is made stiff enough. **Bow.**

REPLIES TO QUERIES.

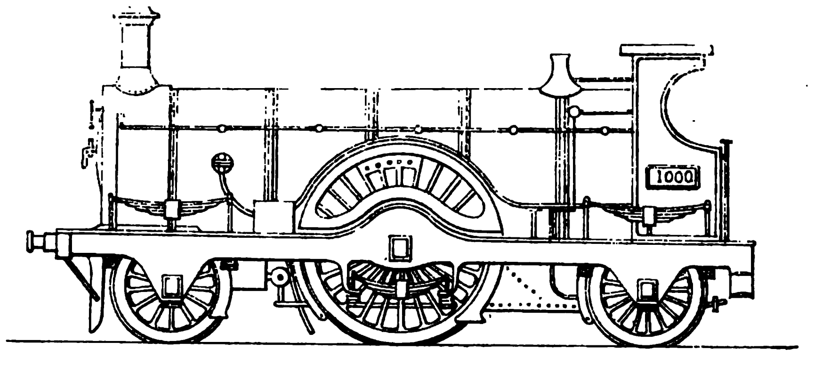
◆◆◆

**** In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[51056.]—**Medical Mesmerism.**—To "Sigma."—As I do not know the causes of the conditions described, I cannot say whether mesmerism would benefit; but it would do no harm, which is more than can be said of most things. The most certain way of benefit would be to obtain the full mesmeric sleep or trance, and let the patient remain in it for considerable periods, diverting his own nervous energy upon the parts, which can be done by telling him to do so. The recuperative power of nature is wonderful under those circumstances. As to direct action by passes, the querist is right in his intention; but the leg ought to be uncovered, and besides the local passes, I should begin and end with others the full length of the body.—Sigma.

[51203.]—**Music.**—"Teacher of Harmony" has pointed out what is doubtless the real difference between the action of the mutation stops of an organ and the forbidden consecutive octaves and fifths in an ordinary work. It is true that in the organ tone the intervals are very much reduced in power, and are put there for a special purpose. Still *they are there*; and so the absolute prohibition given in the textbooks needs modifying. I am much obliged to "Teacher of Art" for the trouble he has taken in dealing with the question. Any consecutive notes will yield the consecutive octaves and fifths on an organ "full to fifteenth"; and as "G. F. H." will scarcely deny that consecutive notes are used by all musicians, I need not quote passages. "Emeritus" takes it for granted that I never heard of Helmholtz or his work, and is good enough to give me a little elementary instruction in the theory of clang-tint, for which I feel very grateful.—Wm. John Grey, Elswick Science School.

[51223.]—**G.W.R. Engines.**—I send a sketch of the 1,000 class of G.W.R. singles as promised. The dimensions are as follows:—Boiler—length, 10ft. 6in.; diameter, 4ft. 1⅛in.; plates, $\frac{7}{16}$in. thick. Outside firebox (Lowmoor iron)—length (outs.), 6ft. 4in.; breadth (outs.), 4ft. Inside firebox (copper) length (outs.), 5ft. 9¼in.; breadth (outs.), 3ft. 6½in. Top of box to grate—5ft. 9½in.; bottom ditto, 3in. Smokebox—length outside, 2ft. 7¾in.; breadth ditto, 5ft. Chimney (taper)—diameter, 1ft. 4in. to 1ft. 6in.; height of top from rail, 12ft. 10½in. Tubes (iron)—250, diameter, 1⅝in.; length, 10ft. 11½in. Pitch of centres, 2¼in. vertical, 2in. horizontal. Heating surface, 1278·5 square feet. Cylinders, 18 by 24; centres apart, 2ft. 6½in. Driving-wheels, diameter, 7ft. Leading and trailing wheels, 4ft.; wheel base, 8ft. 6in. + 9ft. Frame—extreme length, 25ft.; extreme breadth, 6ft. 9in. Distance of centres of frame (inside), 4ft. 0½in.; ditto (outside), 6ft. 6in. Weight of engine (full), 32tons 10cwt.; ditto (empty), 28tons 10cwt. On page 416, No. 954, I gave a complete list of the G.W. singles (narrow gauge). I wish to add a few words in addition. Nos. 7 and 8 (Wolverhampton, 1859), have 6ft. 3in. wheels and cylinders 16in. diameter; No. 30 (1860), 6ft. 6in., 15in. cylinders; No. 110 (1862), 6ft., 16in. cylinders; 209—214 have 6ft. 6in. wheels and 16in. cylinders; Nos. 7, 8, 30, and 110 are not rebuilt engines, as I there mentioned, but came out new at the time. A drawing of the 157—166 class appeared in Vol. XXXIV. page 94. This letter, together with that on page 416, Vol. XXXVII., contains all the information required on G.W. singles, and I hope it answers many past queries. The tenders of the broad-gauge engines are shallow, because they hold quite enough water without additional height, owing to their great breadth. In this they have an advantage over the narrower tenders of the N.G.—Meteor.



[51228.]—**Deflection of Girder.**—The original question is rather unintelligible. The formula for the deflection of iron girders is as follows:—$\Delta = \frac{W \times L^3}{S \times D^2 \times 60}$ for wrought iron when Δ is the deflection in inches.

W = weight in tons in centre.
L = span in feet.
S = sum of the areas of the top and bottom flanges in sq. in.
D = depth in inches.
60 = constant when W is in centre of wrought-iron girder.
100 is the constant when W is weight in tons distributed on wrought iron.
40 is the constant when W is in centre of cast-iron girder.
66 is the constant when W is distributed on cast-iron girder.

—J. S. C.

[51242.]—**Secretary's Liability.**—This query, which is replied to by Mr. Wm. Jno. Grey, escaped my notice. If "Ireland" rented the room used by the society for their meetings, on their behalf and by their instructions, he would not be liable for the rent. Much, however, as Mr. Grey observes, depends on the form of receipt given for the rents which have been already paid. He should see in future that receipts should be made out something like the following:—"Received of the ....Society, per Mr................. the sum of £............for........quarters rent of the room used by the Society." The above is merely a precedent, which you can alter to suit your purpose.—G. Russell Pridham.

[51253.]—**New Zealand.**—I am of opinion that if you scratch "London Stone" you may find a Yankee land-jobber. Or, Dick Whittington like, he went to N.Z. expecting the streets to be paved with gold; though, unlike him, he failed to turn them to gold by the necessary labour. I have given considerable study to our colonies, and from a book now before me, written by a clergyman resident in N.Z. for many years, I quote the following: "The charm of N.Z. is its winter. The extremes of the English climate are unknown there. Fogs are unknown there. All English fruits flourish there: also figs, apricots, peaches, grapes, oranges, and lemons are grown, and ripen." The late Bishop Selwin wrote: "A sparkling breeze, a smooth sea, a cloudless sky, give that undescribable sensation of a really fine day which I have never felt elsewhere." After forty years, the Rev. J. Buller writes: "The climate is equable; it is both healthy and pleasant. Droughts are unknown, and floods are rare. There are occasional gales, but no hurricanes; the sky is generally bright, and the air pure." Dr. Thompson, who spent some years in N.Z., and who wrote a valuable work called "The Story of N.Z.," states that he found the death rate amongst British troops to be, per year per 1,000: Canada 20, Malta 18, Cape 15, England 14, N.Z. 8. Mr. Giffen's report to the Board of Trade gives the average yield of wheat to be 31 bushels, barley 35 bushels, oats 38 bushels, potatoes 5 tons per acre. Sir Julius Vogel confirms this, and states that the N.Z. farmer has an advantage over his brethren in Australia, the Cape, or in America, in the ratio of 10 to 1. So much for the Comonodore. In conclusion, don't let "Old Subscriber" or "Engineer" be frightened by the scarecrow stuck upon "London Stone"; but let them read "New Zealand," by Rev. J. Berry, James Clarke and Co., 14, Fleet-street, price 6d.; and the "New Zealand Handbook," to be obtained from the Agent-General for N.Z., 7, Westminster-chambers, Victoria-street, price 1s. 6d Wm. H. C., Ashton-on-Ribble.

[51484.]—**Three-Manual Reed Organ.**—I am glad to see that "Joiner" has come forward to help "G Minor" with his three-manual reed organ: and as the latter gentleman has expressed a wish for a brief specification, I now furnish one, which I hope will be found useful to him, and to anyone else who may like to build one of a similar class. Upper Manual.—Diapason 8ft., bassoon 8ft., piccolo 4ft., principal 4ft., voix celeste 8ft., saxaphone 8ft., wald flute 2ft. Centre Manual.—Diapason 8ft., principal 4ft., dulciana 8ft., flute 4ft., hautboy 8ft., contra bass 16ft., violoncello 16ft. Lower Manual.—Clarionet 16ft., cornet 8ft., musette 16ft., ophicleide 16ft., concert flute 8ft., flute harmonic 4ft., principal 4ft., sub-bass 16ft. Pedal organ, 4 sets of 30 notes each, as follows:—Sub-bourdon 32ft., bourdon 16ft., bass trombone 16ft., diapason 8ft. I would suggest two manual couplers, one of which will couple upper manual to centre manual, and the other to couple centre manual to lower manual. A pedal coupler may be added so as to connect manuals to pedals. Twenty full sets of reeds will not be required in this specification, which will evidently prove to be of sufficient variety for any reed organ, and as all these varieties of tone can be obtained by the skilful voicing of the several sets of reeds, it would not be advisable to introduce any further number of stops for the sake of mere imagination, or repetition of the same thing over again. I wish "G Minor" every success in his undertaking, and I hope, when he has completed it, that he will favour us by making known the results. I have left the choice of mechanical stops entirely to his own judgment except the couplers. A vox humana could be placed in connection with the reeds of the upper manual, if desired.—G. Fryer.

[51587.]—**Preparing Millboards, &c.**—"An Amateur" having asked for directions how to prepare millboards (in "E. M." of Sept. 7th, page 23), I venture to send him the following method, extracted from a work which I have had since the year 1839 (date of publication), but now probably out of print. The extract is a portion of the fifth chapter of a work on "Oil Painting," and translated from the original French treatise of M. I. F. L. Mérimée, at that time secretary to the Royal Academy of Fine Arts in Paris. As this account of the process of preparation differs in some respects from those answered in the following number of "E. M.," it may probably interest our querist. The chapter is headed, "On the Preparation and Grounds of Panels, Canvases, and Walls." After a few preliminary observations concerning panels, the advantages of canvas, as uniting cheapness and easy removal, whereas panels were often fixed to a particular place, the writer proceeds as follows:—"It is natural to suppose that panels composed of several pieces glued together might become disunited by the changes arising from dryness or moisture, to which pictures are always more or less subject. To prevent these accidents, very great care was taken in the earlier times, but latterly these precautions were neglected; bands of linen were glued upon the joining, and even occasionally they covered the entire surface of the panel with black tanned leather. The gluing on of linen bands is attributed by Vasari to Margheritone, who lived in the twelfth century; but it was known before his time, for the practice is described in Theophilus' treatise, De Arte Pingendi; it was probably brought into Italy by the Greeks." The writer then goes on to inform us from Theophilus that the planks or boards of which the panels were composed, were prepared, and "cemented at their edges by a glue made from cheese"; he then proceeds to explain at some length how this glue is prepared, after which we read as follows:—"The panels were anciently primed with chalk, dissolved in animal size; it is the same preparation which is still used by the wood gilders in preparing their frames and other work. Plaster ground is preferable to chalk, and the term *ingessare*, "to cover with plaster," is used by the Italian authors to describe the application of distemper grounds to panels. I have had occasion to analyse a portion of the ground of a picture by Titian, painted on wood; this ground was composed of plaster of Paris, with starch, and paste, but no glue or size, flour paste being used instead of gelatine. There has also lately a curious fact been discovered, namely, that a couch of distemper, which covered the envelope of a mummy, was composed of plaster mixed with animal glue. In the commencement of the art the canvases were prepared like the panels, with distemper grounds; and it has already been stated, that generally the pictures of Paul Veronese were painted upon such primed cloths. The practice now is, to prime the cloth with oil colour, changing the mode according as the canvas is of a closer or more open texture. When the canvas is very open, and lets the colour through, it must be saturated with size made of glove parings, laid on with a large palette knife or trowel, the edge of which should be blunt, and a straight as a rule, that the couch of size may be laid as evenly as possible; when the priming is quite dry, it must be rubbed with pumice stone, to make it free from lumps; then with a knife, a couch of ceruse is applied; when dry, this is also pumiced; a second couch is then put on, and sometimes a third, to obtain a perfectly even surface. Formerly the priming was made with dark red mixed with umber, or with pure umber; and some sixty years it was supposed that the drying of this colour would be quickened by mixing it with litharge: but it has been discovered that pictures painted on these sort of preparations, in a few years have their surface covered with a multitude of little grains like sand, and thus proving that the litharge was badly prepared. At the present day, the artists are more careful in such essential matters, and the colourmen, for their own sakes, are excited to prepare their canvases with more attention, for any negligence in these essential matters would ruin their trade. Cloth for priming without sizing ought to be of a closer and more even texture; in this respect ticking is peculiarly advantageous; for though at present it is not to be had of a much greater width than two yards, yet, if the manufacturers found a demand for it, they, no doubt, would make it up to any reasonable dimensions. If the cloth is not sized, it will require three or four couches of colour to insure an even surface; and before a new couch is applied time must be allowed for the former to dry hard enough to be rubbed with pumice. This is the reason why cloth requires in preparation two or three months in summer, and five or six in the winter season." (*N.B. The advantage in priming the cloth first with size is, that it prevents the absorption of the oil through the canvas, besides affording a closer and harder surface upon which to work with dry pumice stone.*—G. H. L.) "The time required for priming may be shortened very much, by making the first and second couches with distemper; and as soon as they are quite dry and pumiced into an even surface, let the last couch be merely oil, which has become viscous by exposure to the air; this will penetrate the distemper and render it quite pliant. By the former method much time is required to dry the cloth. But by this mode, as soon as the oil is absorbed, they may be rolled up like waxed cloths with perfect safety. As the pliancy of these cloths depends upon the complete union of the oil with the distemper, the absorption would be greatly facilitated by using a very weak size, mixed with a little oil, and a good quantity of mucilage of linseed meal, or the latter mucilage alone will do if well boiled." Thus far, says our author, he has not touched upon the preparation of millboards; but the process is the same. The directions for preparing, as given in "E. M." of September 14, page 44, by "E. B." Dublin, and "Fisherman," are both good; but the "mistake of the latter lies in this, that he brings in "water" as an element to assist the operation. Dry powdered pumice rubbed with the pumice stone itself will do far more than the water will effect—to say nothing of the dirt and slobber it will occasion—but as water is the element of the fisherman, we will excuse our friend in this case with all due deference to his opinion, millboard *is* a good material. It need not of necessity be absorbent. I would only further add that, except knowing how millboards and canvases are prepared, no advantage would be gained either in time or expense by "Amateur" preparing his own "boards," as they can always be obtained ready to hand at any of the artists' repositories.—Geo. H. Lancaster.

[51619.]—**Specific Gravity.**—Mr. Allen has already given you an equation for estimating sugar solutions (p. 150). Solutions of silver nitrate are best estimated by means of the argentometer (an instrument used by photographers), which shows the number of grains dissolved in one fluid ounce. It is not expensive, the price being not more than 2s. 6d. I am sorry I cannot help you with respect to solutions of sodium carbonate.—N. C. R.

[51620.]—**Photographic (U.Q.)**—Although I do not know for certain, there are, I believe, expert photographers in Tasmania, as in most other places, and unless, therefore, "A Would-be Photographer" is also a "well-up" photographer, he would not stand much chance. No doubt apparatus and materials are much dearer than here, and hence it would be to his advantage to take out as large a supply as practicable.—W. Robinson, Jun.

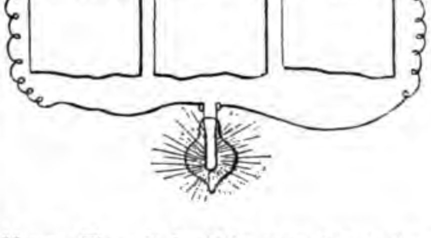
[51626.]—**Polishing Shells.**—These are cleaned by brushing them well in hot hydrochloric acid, rinsing in hot water, and drying in hot sawdust from any non-resinous wood. If the shells are without a naturally polished surface, it must be brought up by means of tripoli and a washleather. Some shells are ground through the outer case to show the pearly laminæ beneath.—Nun. Dor.

[51636.]—**Fish Oil.**—By filtering through animal charcoal you ought to be able to remove the dark colour; but as you want to deodorise as well, better try Dunn's process. Heat by steam to 180-200° Fahr., and then force air of same temperature through until sufficiently purified. There is also a process of stirring up with chloride of lime solution; but unless the new ozone bleach is cheap, you will find nothing so effective in bleaching as filtering through animal charcoal.—Nun. Dor.

[51637.]—**Stone Polishing.**—"Bobbydazzler" must rig up a lapidary's lap if he wants to do much in agate polishing; but if he wants to do a few only, a lapidary will slit them through for him at a small cost. Then to polish, let him wash up some emeries by the method so frequently described, and with a bit of smooth iron plate (glass will do), start a surface with emery, water, and elbow grease. Bring up to a dull polish with the finer emeries, and then finish on a bit of cloth with fine puttypowder. If querist wants to know how to rig up a "lap" or any further particulars, I am sure he will find plenty of information in the back volumes—at least I know I could.—Nun. Dor.

[51647.]—**Amber and Bone Bending.**—Amber can be bent by heating it gently; but some little experience is required, as it is apt to fly. Bone is bent by steaming or boiling, binding into the required shape until cold.—Nun. Dor.

[51659.]—**A Three-Cell Battery.**—(1) As to the solutions, take chloride of ammonium 1¼oz., muriatic acid 1oz., put in the porous cells, and fill up with water. Then make a saturated solution of bichromate of potash, mix 2 parts of the solution with 1 part of muriatic acid, and fill the outer cell within an inch from the top; the two liquids should be level with each other, as per drawing on p. 93 in No. 966. The cells should now be connected together alternately with stout copper wire or strips of copper 6in. long ½in. wide (i.e., carbon to zinc, &c.). (2) Electric bell wire would do; but I should prefer our reader to use the above, as better results are obtained. (3) The ends of the wires proceeding from the zinc and carbon respectively should be connected with the wires from the base of lamp. The ends should be scraped clean about an inch before joining, so as to have a proper metallic connection. (4) This battery will bring up a 2½ c.p. Swan's incandescent lamp to its full power, providing you ask for one of "low resistance" when purchasing. A very beautiful and attractive effect can be produced if the lamp be placed in front of a multiplying reflector. When the battery is not in action, the zincs should be removed from the porous cells and placed in a vessel of water till required for action. I forgot to mention that a little mercury (¼oz. to 1oz.) should be placed at the bottom of the cells in which the zincs are placed.—Electrician.



[51665.]—**Setting Valves.**—Fully explained on pp. 582, 601, last volume, and several times in back numbers.—Essar.

[51667.]—**Fixing and Erecting Machines.**—Answered so recently as pp. 417, 558, last volume. See also indices of back volumes.—Essar.

[51676.]—χ **Cygni.**—The querist should look up the star himself. It is absurd to ask a resident in London for observational information of this star.—C. T.

[51681.]—**Magnetism.**—The answer to this query is yes; but it can be easily settled by a trial. —J. M.

[51688.]—**Hydraulic Lift.**—I don't know where the largest hydraulic lift is situated; but should suppose that on the Weaver Canal is big enough for correspondent.—E. T.

[51693.]—**Chandelier.**—Send it to the lacquerer's. It wants dipping and relacquering. Directions in back numbers; but much cheaper to have it done by those who have the appliances ready to hand.—Essar.

[51730.]—**M. R. Engines.**—No. 140 is a four-coupled bogie tank, single frames, built at Derby in 1875, used for metropolitan traffic, coupled wheels, 5ft. 6in., cylinders 17in. by 24in. No. 195, four-coupled double-framed passenger engine, Beyer, Peacock, and Co., 1867: cylinders 16½in. by 22in., wheels 6ft. 2in.; 195 was rebuilt 1880. 603 is six-coupled goods, Kitson, 1867; wheels 5ft. 2in., cylinders 16½in. by 24in. 1123 is six-coupled, side tank, Neilson, 1875; wheels 4ft. 6in., cylinders 18in. by 24in.; 1632—1636 (1883), bogie tanks, 5ft. 3in. wheels, cylinders 17in. by 24in. In this class the eccentrics are cast on to the crank shaft. 200, 221A, and 1093, six-coupled, double-framed, well tanks. Many of this class were built at Derby 1860—4. I cannot give dimensions. 200 was rebuilt in 1875. 2061, small four-wheeled outside cylinder, saddle tank, by Manning, Wardle, and Co. 880—889 are six-coupled side tanks for Metropolitan goods traffic, by Beyer, Peacock, and Co., 1871. They are very powerful engines, but I am sorry I cannot give dimensions.—Meteor.

[51772.]—**Brighton Engines.**—I send the following dimensions of the new express passenger engine, "Gladstone," now running on the London, Brighton, and South Coast Railway:—

	ft.	in.
Diameter of cylinders	1	6¼
Stroke ,, ...	2	2
Length of boiler (barrel)	10	2
Diameter ,, (outside)	4	6
Length of firebox (external)	6	8¼
Breadth outside, bottom	4	1
Length inside, bottom	5	11¾
Breadth ,, ,, ...	3	4¾
No. of tubes	331	
Length ,, over all	10	8¼
Diameter of tubes outside	0	1½
Heating surface of tubes ..	1372·92 sq. ft.	
,, ,, firebox..	112·48	
Total heating surface..	1485·40	
Grate area..................	20·65 sq. ft.	
	ft.	in.
Diameter of leading and driving wheels	6	6
Diameter of trailers	4	6
,, tender wheels	4	6

The weight is distributed as follows:—

	Tons	cwt.
On leading drivers..............	13	16
,, trailing ,, ...	14	10
,, trailing wheels..............	10	8
Total weight of engine........	38	14

The weight of tender in working order is 27 tons 7cwt., and is distributed equally on each pair of wheels or 9 tons 2cwt. 1½qr. each. Total weight of engine and tender in working order is 66 tons 1cwt.

	ft.	in.
The total wheelbase of engine and tender is	38	9½
From centre of leader to centre of driver........................	7	7
From centre of driver to centre of trailer	8	0
Total wheel base of engine..	15	7
Tender—		
From centre of leading to centre of centre wheel	7	0
From centre of centre wheel to centre of trailing	7	0
Total tender wheel base	14	0
Capacity of bunker	2 tons	
,, ,, ...	2,250 gals.	

The "Gladstone" is painted the usual colour of L.B. & S.C. Co.'s engines—viz., yellow, picked out with black and red lines. It is fitted with the Westinghouse automatic brake on the wheels of the engine, and also, I believe, on the tender. It was designed by Mr. Stroudley, and built at the company's works at Brighton. I may mention that the cylinders are cast in one piece, and the slide valves and ports are underneath.—H. N.

[51792.]—**Cancer of the Mouth.**—"Observer" writes that he knows a lady who knew a young man who was cured of a cancer in his nose by bathing at a Welsh spring. This must obviously be wrong, for—1, cancer (Carcinoma) never affects the nose in any form except that of epithelioma, which is commonly a disease of advanced life; 2, cancer is in its nature incurable, except by removal either by the knife, cautery, or caustic. "Nun. Dor." attempts to raise a laugh against Dr. Allinson by quibbling with his words, and in reality shows his own ignorance of the meaning of the preposition "of," which, if he will consult any good dictionary, he will find, amongst other things, may mean "produced by"; and it is obviously in this sense that Dr. Allinson uses it. Then, again, he denies what Dr. Allinson asserts, and what is an undoubted fact—that local irritation is the determining cause of epithelioma; and I may say that it must be so from the following fact alone: I have seen about 300 cases of cancer of the lower lip—all men, never a woman amongst them. There are about five cases of cancer of the lower lip in women recorded, and all of them have been smokers. I should take up too much of your valuable space if I took the trouble to contradict all "Nun. Dor's" statements; but their value may be estimated from the above.—St. Bart's.

[51792.]—**Cancer of the Mouth.**—Thanks to "Nun. Dor." for his criticism. I will reply at greater length. Cancer is produced by two causes: a predisposing and an exciting one. The *predisposing* ones are eating too much animal food, and not getting enough fresh air and exercise. The *exciting* ones are irritation of some kind, as of pipes or braces, or even a blow or injury may give rise to it. But in cancer of the lip the exciting cause is the pipe, and the chances are it would not have appeared there but for the pipe. But because cancer appears on the lip from the friction of the pipe, I hope "Nun. Dor." does not infer that it would have appeared elsewhere if it had not appeared there. On the contrary, some other disease might have set in and cleared the system of the material predisposing to cancer. It is clear to anyone who will take the trouble to inquire, that an epidemic of small-pox lessens for a time the deaths from cancer; in other words, small-pox attacks those whose systems are in such a state as to favour the development of cancer, and either kills them off or else clears the system of waste matter, and so cancer cannot arise. "Nun. Dor." must not quarrel with words, and speak of "an irritated pipe"; but I will remind him of one of his slips. He speaks of tobacco as a harmless *vice*. Now a vice is never harmless, and I am glad that he acknowledges the tobacco habit to be a vice. "Nun. Dor." again quarrels with words about "the prevalence of cancer." If he will look at the heading of my reply, he will find it "Cancer of the Mouth," and my answer about it being "uncommon in women and non-smokers" meant that it is uncommon in these people in that particular situation. As to the connection of cancer in other parts of the system and the tobacco habit, I cannot give any information, as I know nothing about it. As to the cure of cancer, I have heard, just lately, of a case, where a diet from which all animal food has been excluded, together with bathing, has almost effected a cure. If it effects a cure, more will be heard of it. "Nun. Dor.'s" Parthian arrow I will not return; but I see an opening in his armour where I could thrust it and give pain. I fight not with men, but with their opinions and beliefs.—T. R. Allinson, L.R.C.P., &c.

[51796.]—**Photographic.**—Yes; gelatine plates answer admirably for this sort of work, though they need not be "slow" ones. The main points are to avoid over-exposure, which would tend to "flatness," and to keep the developer well restrained, so as to get sufficient density. The exposure is sure to be a good deal longer than for landscape work; but when once you ascertain the correct time, you should be able to do a lot without any material variation.—W. Robinson, Jun.

[51822.]—**Pyro.**—I remember purchasing a bottle of pyro., answering this description, some eighteen or twenty years ago, though I believe it was of English manufacture. It was O.K., and kept good for many years, pyro. not being so much used in those days.—W. Robinson, Jun.

[51826.]—**Brakes on the L. and N.W.**—In my reply, page 135, I mentioned that the north portion of the 7.15 a.m. from Euston was fitted with the chain brake, but that it was about to be removed from the West Coast Joint Stock. This change is now being carried out, and the north portion of the 7.15 a.m. train will now be formed of carriages fitted with both Westinghouse and vacuum brakes; the next train ordered to be fitted is the 10 a.m. from Euston, the vehicles being nearly completed. It is stated at Crewe that in a year the chain brake will be a thing of the past on the main lines.—Clement E. Stretton.

[51845.]—**Photo. Studio.**—If you will refer to my reply to No. 50635, p. 391, of last volume, you will find some hints that may be useful, though in matters of this kind it is not easy to give sound advice without being personally acquainted not only with the dimensions, but also with the surroundings, of any proposed studio. Generally speaking, a north light falling in front, and somewhat to one side of the sitter, is best; but if unattainable, a good deal may be done in the way of modifying an unfavourable light by the judicious employment of reflectors.—W. Robinson, Jun.

[51848.]—**Lost Watch Wheel.**—As there are a few errors in this reply I hasten to correct them. Line 12, read "gives two vibs." Line 9 from bottom of same column, read "than there are leaves." Page 158, lines 12 and 13, leave out "by"; read "when the product of the fourth wheel, 80, 64, and 30, is divided by the product of the." Line 16 from bottom, fourth term, read "·1117." Lines 7 and 6 from bottom, read "the rule is, as the diameter of the wheel is to its No. of teeth + 2·25, so is the P.L. to half sum of wheel and pinion." All is now right to end of reply. In continuation of this subject, allow me to say that the pinion's diameter can be found as stated in 16th line from end of reply, p. 158, as well as from the third wheel (in the case of a lost fourth pinion). In this latter case we have the number of third wheel and its diameter, and having found that the fourth pinion must be an eight, state the proportion thus:

Wheel. Diameter. Pin. Diameter.
62·25 : ·73235 : : 9·5 : x = ·1117.

The addenda 2·25 is given to the driver, and 1·5 to the driven, be it wheel or pinion. In replacing a wheel and pinion, as in this case, to make it successful, it is well to examine the shape of the third wheel teeth, and leaves of the escape pinion, for if the wheel has more tooth than space, the fourth pinion should have thin leaves, and bay-leaf shaped, as also the teeth of the fourth wheel. Care should be taken there is no drop or rubbing in of the teeth. As regards the wheels and pinions for showing the hours and minutes (commonly called "the motion," or dial wheels), the two pinion's numbers may be assumed, and their product + 12 (the ratio of the minute-hand's revolutions to the hour hand) gives a product to be divided by prime numbers, as was done in Ex. *a a'*, *b*, *c*, and rightly arranged the numbers for the minute and hour wheels, thus: Let the assumed numbers be 12 and 10, then 12 × 10 = 120 × 12 (the ratio) = 1440, and being divided by

$$36\left\{\begin{array}{l}\left\{\begin{array}{ll}2 & 1440\\ 2 & 723\end{array}\right.\\ 40\left\{\begin{array}{ll}2 & 360\\ 2 & 180\\ 2 & 90\\ 5 & 45\end{array}\right.\\ \left\{\begin{array}{ll}3 & 9\\ 3 & 3\end{array}\right.\end{array}\right.$$

we have cannon pinion = 12, mt. nut = 10, hour wheel = 36, mt. do. 40. This can be done another way, thus: Write down 3 × 4 over these figures, whatever numbers you like for the pinions. $\frac{14}{3} \times \frac{16}{4}$ × the upper by the lower, gives 42 and 64 for hour and mt. wheels, = 12 hour motion. If for a 24 hour— $\frac{14}{6} \times \frac{16}{4}$ pinions. = 24 hour
84 64 wheels.

—R. E. B.

[51863.]—**Arranging Brass-Band Music.**—If I rightly understand this query, "Euphonium" desires to know how to arrange some music to play on a band of 24 instruments which he already has, and does not require information—as G. Fryer seems to suppose—as to what instruments to form the band with. To give sufficient instruction here would occupy far too much space, but if "Euph." will send me something he would like to play, I will arrange it for him. He will get more information from a thorough study of the score than from half a dozen pages of written matter. If I misunderstand query, and "Euph." does want to know what instruments to form band with, I beg to submit following:—7 cornets as follows: 1 soprano, E flat; 1 solo, B flat; 2 firsts, B flat; 1 repieno, B flat; 2 seconds, B flat; 5 tenors, E flat (1 as solo), 2 tenor trombones, B flat; 2 baritones, B flat; 1 solo euphonium, B flat; 1 bass euphonium, B flat; 1 bass trombone in G; 2 bombardons, E flat; 1 bombardon B B flat; side and bass drums.—J. Johnson, Huyton, Liverpool.

[51864.]—**Indicator Diagrams.**—To A. A. Myall.—I am sorry to say the diagrams I sent were reduced by the engraver to about one half the size. They are now a little large of $\frac{1}{48}$th scale. The greatest pressure of steam we get is 27lb., and about $9\frac{1}{2}$ to 10lb. vacuum, with particulars as stated in my query. Shall be pleased to hear from "A. A. M."—P. A. D. [People sending diagrams should have some little consideration for our space! —Ed.]

[51895.]—**Old Files.**—None of your readers seem to give a good answer to the question of making chisels out of old files. There is no need to soften them, as to do so means hardening again and tempering afterwards, and as old files, or files generally, are hard, all that is needed is to temper them a little lower; in fact, they will make good chisels or turning tools as they are; but being harder than required, they chip. All that is wanted is to let them down, as we call it, which is done by making bright, by rubbing on a grindstone or flagstone until there is sufficient bright surface to watch the heat given them to produce a straw or deep straw colour, then stop and let cool. The best way to effect this is to put a piece of bar-iron into a fire and make redhot, then place the file with the bright surface upward, and watch for the straw colour coming up; then let cool, taking care that the file does not remain on the hot iron until it takes a silver colour, for then it would soon lose its edge for cutting. I have cut old plyers out of a chisel made in this manner.—A Reader of "E.M."

[51899.]—**Medical Coil.**—"Thor" says I have made a mistake; but may I tell "Thor" that before I answered his query I placed a small coil that I have, inside a tin tube, and also wound some thick copper wire round it, and in both cases it worked all right. Will "Sigma" please say why it should not work? I thought induction would go on in the coil as well as in the tube, which I found was the case when I tried my coil with the copper wire round it.—Watt.

[51899.] — **Medical Coil.** — Considering the further remarks (p. 158), I may inquire why on earth (or tropical Africa) such a complication as a coil and a thermopile should be used at all? Why not be content with a portable magneto-electric machine, which will do the same work? If a little magic is wanted, a coil could be made up in one hand and the cell in the other by making the handle out of a split cylinder instead of a tube, and connecting the two handles by a pair of wires carrying the current from battery to coil. The battery might be a good chloride of silver one, such as is made up in ebonite tubes. A fine wire would be wanted to connect one terminal of three to the further handle, and all secondary wires could be made into one.—Sigma.

[51908.]—**Shakespeare on the Stars.**—I trust "F.R.A.S." will excuse my supplementing his reply about "the unfolding star" in "Measure for Measure," Act iv. Sc. 2. In my edition of Shakespeare (Stevens, 1803), the following quotations are given in illustration:—

> "The star, that bids the shepherd fold,
> Now the top of heaven doth hold."
>
> —Milton's "Comus."
>
> "So doth the evening star present itself,
> Unto the careful shepherd's gladsome eyes,
> By which unto the fold he leads his flock."
>
> —Marston's "Insatiate Countess," 1613.

—Charlie.

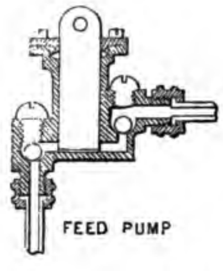
[51908.]—**Shakespeare and the Stars.**—The replies given to this query do not appear to me to be correct, and are not in accordance with the usual explanations. The "watery star" of the "Winter's Tale" is simply the moon, of which Shakespeare speaks in the "Midsummer Night's Dream" as "the moon, the governess of the floods." "The stars, I see, will kiss the valley first," is but a poetical expression for never; and "the unfolding star which calls up the shepherd," in "Measure for Measure," is the morning star, which warns the shepherd to unfold his sheep. Astrology is referred to a hundred times by Shakespeare, but none of these passages have anything to do with it.—Achespe.

[51912.]—**To Violinists who are Mathematicians.**—The problem presented is one that admits of solution. It will be necessary to have accurate knowledge of the mathematics of music, so far as in this case they apply, before a mathematical demonstration of the kind postulated can be formulated. The violin being tuned in fifths, and the ratio sustained by fifths in music being as 2 to 3, if the violin is in perfect tune and the G string being taken as 2, D will be to it as 3; and, again, D being taken as 2, A to it will be as 3, and similarly with respect to A and E. It has been ascertained that the lowest sound that can be appreciated is produced by vibrations at a ratio of 27 per second of time, while the highest is that of 37,000. The question here is, how many vibrations per second produce, for example, the Philharmonic A on the violin, how many E, D, and G? This requires first to be correctly ascertained. It has been said that students who have undergone a tonic-sol-fa course of musical instruction experience, comparatively with other pupils, little difficulty in learning to tune the violin when put to that instrument. Perhaps some mathematical tonic-sol-faist will kindly assist in throwing light on this question.—Student.

[51926.]—**M. R. Locos.—Goods Engines.**—Wellingborough, 720—739; 1150—1221 (with a few exceptions); London, 760—779; Bedford, 840—849, 454, &c.; Leicester, 621—659 and 240—259 (including Wigston); Nottingham, 224—229, 310—329, 450—479 (most); 1599—1601, &c.; Skipton, 383—385, 1371—1374; Carlisle, 1222—1243; Manchester, 1452—1471.—Meteor.

[51944.]—**Coppered Wire.**—S. Austel is in error in stating that copperas is employed for coating iron with a film of copper. He probably meant sulphate of copper (bluestone). The query was correctly answered by Mr. Bennett.—[illegible], F.C.S.

[51914.]—**Feed Pump.**—Here is a sketch of a pump which may suit your purpose. As you



FEED PUMP

intend fixing it on the boiler, you had better have the plunger large enough, say ¼in. diameter, so that the pump will be able to start of its own accord when hot, as it will be sure to get so when fixed as you say. If you do not have a good suction, the pump will not be able to draw the water without your dropping some cold water on to cool it. The valves are ball valves of selected lead shot, which I have found answer the purpose admirably.—S. Austel.

[51943.]—**Income-tax.**—I believe the Friendly Societies are exempt from this tax. The amount deducted can be reclaimed from the local Inland Revenue Office, by obtaining from the bankers, each half-year, a certificate of the amount deducted. If preferred, this need only be done once in three years, as claimants are allowed a return going back to that time.—Shylock.

[51945.]—**Boiler.**—The boiler built with the greatest number of rings of plates is the strongest, from the fact that there is a greater amount of metal in the same length of boiler—that is, supposing the boilers are both plated alike; but if one is plated with the longitudinal seams in line, and the other in break joint, then the break joint plating will be strongest, irrespective of number of rings of plate.—Boswell.

[51945.]—**Boiler.**—My short answer to this query was, unfortunately, too late for last week's issue, so, now, having a little spare time, I will try to further explain the difference in point of strength of boilers constructed as shown by "C. T." In my former answer it will be seen that I consider the boiler of 11 rings stronger than the boiler of 8 rings; my reasons for which are as follows:—The formula for bursting pressure in a longitudinal direction is $P = (2\,T\,C) / D$ (P = pressure, T = thickness in inches, C = tensile strength of metal, and D = diameter in inches), and for pressure tending to burst cylinder in a transverse direction is $P = (4\,T\,C) / D$, from which it will be seen that a boiler shell is weakest in a longitudinal direction. Hence the custom of double riveting longitudinal seams, the seams being the weakest part of shell, and the longer the seam the weaker it is. Hence the custom of arranging plates to break joint, the old system of seams in line being now obsolete, on account of their weakness; therefore the greater number the rings of plates, the shorter the longitudinal seams, thus increasing their strength, and reducing their liability to leak. It is argued that the greater the number of seams the greater the liability to leakage and seams giving out. This is all very good as far as longitudinal seams are concerned, but quite a different thing with ring or transverse seams. Under ordinary fair working conditions, ring seams are never known to give way; it is only in exceptional cases, such as excessive straining from overheating, &c., which causes ring seams to give way. Any of our friends who have seen a boiler tested to destruction will readily bear me out, when I say boiler shells of ordinary construction always fail in a longitudinal direction, and leakage from ring seams is due to imperfect workmanship. Again, the overlap at each ring seam is an extra thickness of plate, equal to a belt, so that in eleven plates there would be ten of these overlaps or belts, while in the boiler of eight rings there would only be seven of these overlaps or belts. (Here is the idea of one of our correspondents a few weeks ago, who asked if separate belts could not be applied.) Thus, with ordinary lap seams, there would be equal to 7½in. more metal in the first boiler than in the second, which would make it about 2 per cent. stronger. I have known cylinders made of narrow plates, specially to gain strength, by seams overlapping each other, due care being taken as to placing of seams, and I know of a vessel being made, about 25ft. long, to carry a pressure of 1,500lb., which had to be made of weldless rings of about 1ft. wide; wider plates could not be made to stand, the wide plates being given to buckling and bulging. There are many points about every boiler which might be of more importance than those given by "C. T.," such as openings in shell, and how strengthened, and under what conditions are boilers working, and how are seams spaced—in line or breaking joint; what about end plates and furnace tubes? These should always be given in boiler queries.—Boswell.

[51952.]—**Stage Micrometer.**—Draw your micrometer in black lines on a white surface on a large scale; take a negative of it, making same as sharp in the lines and as dense as possible. Take a little asphaltum, powder it, and drop a little into about ½oz. of benzole, which will dissolve it freely; make it about as thick as collodion. Pick out the clearest 3 by 1 glass slip you have, clean well, and rub one side with French chalk. Coat chalked side with the asphaltum solution, put it on your turntable, and whirl it till the benzole evaporates and leaves a film of asphaltum on the slide. Lay it aside to set for 24 hours. Now take your negative, and putting the asphaltum-coated side of the 3 by 1 slide next to table, put your negative collodion film side also downwards upon this, bind together at the ends with a bit of gummed paper; make a brown paper tube, 4ft. or so long, and expose to the light in it, in such wise that the light passes through the negative to asphaltum film. The exposure will vary from one hour to ten, according to light; but a trial or two will put you right. When you judge it to be sufficiently exposed, place it in a developing dish, and cover over with about ½in. of spirits of turps; this will have a feeble action on the asphaltum film; pour it off, and add a little benzole, and pour over slide again, and it will dissolve film more energetically. You may assist the development with a camel-hair brush; continue till the lines appear sharply defined on the clear glass beneath. Let us know how you succeed.—G. W. W., Newcastle.

[51958.]—**Electro-Plating.**—The fault lies in the bath. You have too little free cyanide. There should be a certain proportion of cyanide of silver and a certain proportion of free cyanide. This free cyanide attacks the anode and dissolves it, supplying the solution when all goes well with just as much metal as is deposited on the goods. If care is not taken to keeep up the right quantity of free cyanide, the bath gets poorer in silver, and loses part of its conductivity. If the anode is very white in working, there is too much free cyanide, and if dark too little. When the proportion is right, the anode appears a cream colour or very pale grey during the passage of the electricity, and turns to white when the current is stopped. Add cyanide of potassium to your bath; but you will probably find, if you have worked it much in the bad condition it is now in, that you have robbed it of silver as well; therefore add a little silver. Always work with an anode surface as nearly as possible the same as the surface of the goods, and if your solution is in right order, just as much will be dissolved off the anode as is thrown on to the articles. If this causes too much electricity to pass, you must reduce your battery power rather than decrease the size of anode. The strength of silver in solution can be brought up to what it requires to be, by using too large an anode until the quantity required is worked in.—J. E. A.

[51972.]—**Valuation.**—Assuming that the property is occupied for the 19 years, it would bring in (if the rent were put out as received to compound interest at 5 per cent.) approximately £3,050, which should equal the sum paid for the property with compound interest at 5 per cent. Therefore, by application of the formula [$A = P\,(1 + r)^n$], you have—

$$3050 = P\,(1{\cdot}05)^{19}$$
$$\therefore 3050 = P\,(2{\cdot}533 \text{ nearly})$$
$$\therefore \text{Principal} = 3050 / 2{\cdot}533 = £1{,}204 \text{ or } £1{,}200 \text{ nearly.}$$

Deducting £100 to cover probable expenses and loss of rent, you have left £1,100, which you might safely pay for the property.—J. P. Stafford.

[51973.]—**Velocity of Steam.**—The velocity of steam into the atmosphere is given by the following formula:—

$$v = 12{\cdot}15\sqrt{P\,S}.$$

where

v = velocity in feet per second.
P = pounds per square inch of steam above atmosphere.
S = specific volume of steam at the given pressure (i.e., the cubic feet of steam evaporated from one cubic foot of water.)

Taking the value of S from Molesworth, and assuming atmospheric pressure = 15lb. per square inch, the velocities for pressures of 10, 20, 30, 40, 50, 60, 70, 80, 90, 100, 125, 150lb. per square inch above atmosphere are 1,212, 1,470, 1,592, 1,670, 1,730, 1,765, 1,800, 1,829, 1,864, 1,870, 1,905, and 1,938, as calculated roughly on slide rule.—Glatton.

[51974.]—**Engine.**—To "Glatton."—I do not quite understand this query. Is the port in valve made so long that the three cylinder ports are all connected when valve is at half-stroke? Zeuner's diagram may be used to solve such questions, and if the Editor will insert it, I should be pleased to describe its application to such a case as I have supposed yours to be—an application which I have not seen published. —Glatton.

[51977.]—**Ejector.**—I have generally found that when an ejector has to force the water above 2ft. or 3ft. vertically, it is better to put it into the water to be forced. But the one you mention may be ticklish from other causes. There ought to be plenty of water space round the steam cone, and the delivery should be larger than the steam supply. Thus, ½in. steam supply pipe and ½in. suction should have ¾in. delivery. I made an ejector a little while ago, out of some gas sockets. With 35lb. steam it would lift 3ft. vertically (suction), and force 12ft., and would work with the water at 80°.—Labor Omnia Vincit.

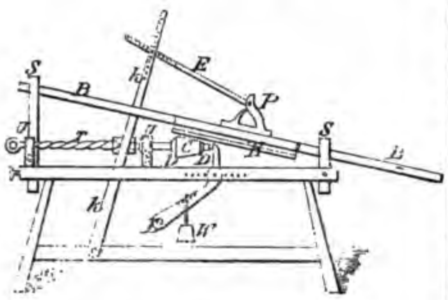
[51977.]—**Ejector.**—Does the water come out full bore in a solid stream when working, or is it white and broken? If the latter, as soon as the ejector has started, turn the steam off slightly until the water comes out in a more solid jet. If this does not answer, put a length of pipe, say, 18in. to 24in. long, between ejector and the boat's side. I have been told that this has cured this fault in cases similar to yours, but I cannot speak from experience, as all the ejectors I have seen worked well. If you think the proportion of the jet in fault, I will give an opinion if you send a sketch to scale of the concern; but I have no rule beyond that of experience.—Glatton.

[51978.]—**Hyposulphite of Soda.**—The following is taken from Lepold Gmelin:—One pound of pure crystallised carbonate of soda is dried as perfectly as possible, and intimately mixed with 5oz. of pure sulphur. The mixture gradually heated in a glass or porcelain basin to the melting point of sulphur, and kept at that temperature for some time, stirring constantly in order to bring every part in contact with the air. The sulphide of sodium formed at first absorbs oxygen from the air, and is converted with feeble incandesence into hyposulphite of soda. The mass, when cold, is dissolved in water, boiled with sulphur for some time, and filtered; the filtrate evaporated to crystallising point. Very fine and pure crystals are obtained in this manner. If heated too strongly, part of the sulphur is burned off, and carbonate of soda remains undecomposed. In this case a second crystallisation is necessary.—George Hart.

[51979.]—**G. W. R.**—There are three classes of B. G. singles, viz., the 2001 class (2001 to 2003) having 18 × 24 cylinders, 8ft. drivers, and single frames throughout; the Alma class having 18 × 24 cylinders, 8ft. drivers, and double frames for drivers, and single for leading and trailing wheels; and the 2007 class (2007 to 2014) having 17 × 24 cylinders, 7ft. 6in. drivers, and single frames throughout. The above three classes have cabs, no domes, and inside cylinders. 2001 to 2003 and 2007 to 2014 once belonged to the B. and E. R., by which company 2007 to 2014 were built about 1870. Before 2001 to 2003 became the property of the G. W. R., they were large single-wheel bogie tanks, having a bogie at each end. Nos. 149 to 156 (narrow gauge) are 4-coupled, inside cylinder, double framed tender engines; having cylinders 17 × 24, drivers 6ft. 6in. They were built by "G. England and Co., London," in 1862, have been rebuilt at Wolverhampton at different dates within the last few years, and have cabs, brass domes, and are mostly stationed at Wolverhampton.—J. E. Spencer, Birmingham.

[51983.]—**Honours: Solid Geometry.**—The querist should use "Payne's Elements" and Angel's large book for the co-ordinate geometry, working every problem, or satisfying himself that he can do so. He may use "Dennis's Third Grade Book for Perspective," which contains more than is needed. Up to last May, these would have been sufficient; but I see from the "Directory" for this year that a new class of subjects has been added to the syllabus for Honours—namely, Graphic Statics, involving—1, the representation of numbers, areas, and volumes by lines; 2, composition and resolution of forces acting in any direction in a plane; 3, graphic determination of centres of gravity in plane figures. 4. Determination of the resultant couple of a system of couples in one plane. 5. Construction of stress diagrams for simple roof trusses symmetrically loaded. These requirements involve some knowledge of mechanics, and being a new addition renders it difficult to advise. The querist might use Twisden's "Theoretical Mechanics," taking care to work the problems by construction. I deem it right to inform "A. P. G." that I have not attempted the Honours examination, and hold only a 1st class advanced certificate. I cannot give any advice as to machine drawing. A book has been published entitled, "The Whitworth Scholarships, and how to obtain Them," price threepence. —Wm. John Grey, Elswick Science School.

[51988.]—**Taper Cork-Cutting Machine.**—A cork-cutting machine is really a lathe with a very coarse screw-cutting arrangement. The sketch herewith will give you a good idea of what the machine is like. A knife K, about 2ft. 6in. long, is guided by a bar B on two adjustable standards S. The cork is made to revolve between two centre plates D. Motion is given to the lathe spindle (which is twisted like an American drill) by means of an adjustable lever F, and attached by a rod E to the plane-handle P. The pieces of cork to be shaped are placed between the centres by the operator, who opens the loose headstock (we will call it), which is also adjustable, by lifting the lever L with his knee. He then, after seeing it fairly centred, takes hold of the handle P, twists it over from him (the knife is attached to the handle, and the handle is attached to the bar by a hinge) a little to make the knife shave off the projecting portions of the cork, when he takes a first stroke; he then brings back the knife, lets it fall as low as it is adjusted to, and then takes the finishing cut, when up goes his knee against the lever L, and out falls the cork into a trough, which carries it away to a basket. The corks are then sorted and packed.—S. Austel.



[51989.]—**Burnisher.**—It is not at all probable that the brass roll is at fault, though as you speak of a "plate" of steel, possibly there may be some other defect in the construction. The burnisher proper consists simply of a bar of steel about half an inch in width, welded on to an iron base. Then, again, do you use a lubricator? If not, make an alcoholic solution of white (Castile) soap, of the strength of two or three grains to the ounce of spirit (methylated will do) and brush it over the prints before burnishing.—W. Robinson, Jun.

[51993.]—**Engine Query.**—An indicator diagram will show the amount of cushioning, also the steam admission, &c. Defective cushioning may be remedied by putting lap on the exhaust side. The thump complained of may arise from the brasses of the plummer blocks being fitted badly or out of adjustment. An engine running at 140 revolutions per minute, requires the valve to have plenty of lead, early exhaust, and well cushioned. With good workmanship, design, and strength, the engine will then work quietly.—Labor Omnia Vincit.

[51993.]—**Engine Query.**—I can hardly wonder at the thumping noise which C. Guillaume complains of with an engine making 140 revolutions per minute. There is no doubt that a certain amount of cushioning in a quickspeed engine is an advantage. But if your noise arises from defective cushioning, just by way of experiment, I should bring the valve forward, so as to make the exhaust close sooner, and note the effect, and then try the opposite ends of the cylinder, so that you will be able to get an idea what amount of lap to put on exhaust side of valve. Keep your crank-shaft brasses hard up, by inserting two pieces of hard wood bevel packing, as I always find the crank side of the brasses to wear the most. With a little care I think you will be able to overcome your difficulty.—Fiber, Dewsbury.

[51998.]—**Brass Whistle.**—The querist can get a fingering scale at any music dealer's. It is practically the same as that of the flute, which I presume he knows, as he adopts the word as his signature.—N. E. Child.

[51999.]—**Steel-Facing Copper Plates.**—The deposition of iron or steel is known as "aciertype." It is, or was, Bradbury's patent, and was worked by them for some years at the office where this paper is now printed. You will, no doubt, find something about Klein's process in Watt or Gore; but if you say what kind of copper plates you mean I will look it up. It is some years since I saw any now; but besides their durability when rust is prevented, they are especially useful where red inks are required, the mercury in vermilion attacking copper with energy.—A Practical Printer.

[52001.]—**Wheel-grease.**—Many others as well as "Simplex" would like a good recipe for making wheel greases, but these are trade secrets the holders of which are not willing to give them up. There are many good wheel greases in the market which can be bought almost as cheaply as preparing them in small quantities. I may say that I have used the spent lubricant for bearings for two years now with very little trouble.—Engineer, Dewsbury.

[52002.]—**New Inman Steamer.**—*The City of Chicago* is 430ft. long between perpendiculars, 45ft. beam, and 33ft. 6in. depth of hold, gross tonnage 5,600. She is divided into eight watertight compartments, and has four complete decks, also a bridge deck 188ft. in length, and a large spread of canvas is carried on four masts. Accommodation is provided for 240 first, 96 second, and 1,200 steerage passengers. The engines are of the three cylinder types, having one high-pressure cylinder 56in. diameter, and two low-pressure cylinders 80in. in diameter, each of 5ft. stroke. The crank and propeller shafts are built of steel, by Vickers and Co., Sheffield, who also furnished the steel propeller blades. Piston valves are issued for the high-pressure cylinder, and all recent improvements have been introduced. Steam is supplied at working pressure of 96lb. by four large double ended and two single ended boilers, having in all 30 furnaces. On her trial trip on 12th September she attained a mean speed of 15 knots. The vessel was built by Messrs. Connell and Co., and the engines by Messrs. John and James Thomson, Finnieston Engine Works.—R. M. S.

[52004.]—**Silk for Flour Dressing.**—Being only a "Country Joiner," I fear you will experience a rather difficult job on what is considered good millwright's work. A reel for 7 sheets "over 24ft. long" between the bearings requires great care in the making, and unless you have had something to do with them before, you must mind how you go to work. Sketches would occupy far too much room for the pages of the "E. M."; however, if you will advertise your address, I will send you particulars.—Millwright.

[52007.]—**Friendly Societies.**—By Section 16, sub-Section 10, of the Friendly Societies Act, 1875, it is expressly provided that trustees shall incur no liability except for moneys actually received by them; and Section 16 generally provides for the investment of the societies' funds. It appears that the trustees of the society referred to in the question are mortgagees in possession, and—that being so—nothing in the Friendly Societies Acts alters their position from that of other mortgagees in possession.—E. F. Brabrook.

[52008.]—**Poor Rates.**—Poor rate is assessed on the real or probable letting value of a house, and if "T. T.'s" house would let for more than the others, it should be assessed higher. If, however, he has a real grievance, he must find out from the clerk to the board of guardians when the next meeting of the assessment committee takes place. He will then have to give notice to the clerk and to the collector that he intends to appeal on that day, and he will then have to attend and state the nature of his claim to the committee.—K. W.

[52008.]—**Poor Rates.**—The rate collector has no right to make a rate or determine the assessment. That is for the assessment committee to do, and his business is to collect the rates. The assessment for rate is five-sixths of the rent the house will command in open market. If, in consideration of a premium, it is let on lease at a lower rent than it would really fetch, that has nothing to with it. The annual value is the amount to be determined. You know your own business best; but I should refuse to pay, and allow Mr. Collector to summon me.—Nun. Dor.

[52012.]—**Bicycles at Night.**—A bicyclist who, instead of a lamp, carries a "flaming torch," deserves a ducking in the nearest canal. Ask your brother bicyclists, and learn something of the amenities of civilised life.—Nun. Dor.

[52012.]—**Bicycles at Night.**—The "Model" Laws read: "Every rider must carry attached to his bicycle a lamp lighted to show a light in the direction he is going," or similar words. If these by-laws are in force, I should say legally a torch is not a lamp; but in any case, no man would be *justified* in any way in throwing you from the machine.—Dozey G.

[52012.]—**Bicycles at Night.**—The various County Authorities have power to make by-laws as to bicycle riding. The following is the general form of clause as to carrying lights:—"Every bicyclist who rides a bicycle during the hours between sunset and sunrise shall carry, attached to his bicycle, a lamp, which shall be so constructed and placed as to exhibit a light in the direction in which he is proceeding, and shall be so lighted and kept lighted as to afford adequate means of signalling the approach or position of such bicycle." Offenders are liable to a fine of two pounds.—Robert Todd, Hon. Sec. National Cyclists' Union.

[52012.]—**Bicycles at Night.**—The law requires you to carry a lamp on your bicycle at night. You were legally wrong in not so having a lamp; but as you carried a torch, it is reasonable to suppose the man saw you coming. He, not being a policeman, had no right to stop you, and if you were injured by being thrown off you could summon the man (if found) for assault. If Mr. Newman was not seriously injured by the fall, I should not advise him to do anything of the sort, as he was clearly technically wrong—even though, perhaps, the man was unaware of it—in riding "without a light," i.e., a lamp *affixed to the machine*, and he might be fined for so doing. The law merely requires you to carry a light for the protection of foot-passengers, who have as much right to walk on the carriage-way as vehicles have to use it. The light being affixed gives you the full power of both hands, whereas in carrying a torch you have the complete use of only one.—G. Russell Pridham.

[52012.]—**Bicycles at Night.**—In reply to G. Newman, the rules regulating lights at night, being made by the different local boards, vary slightly in wording; but, as a general rule, he may consider that the following is the regulation:—"Every bicyclist who rides a bicycle during the hours between sunset and sunrise shall carry, attached to his bicycle, a lamp, which shall be so constructed and placed as to exhibit a light in the direction in which he is proceeding," &c. Bicycle now comprehends tricycle. Strictly speaking, the querist's dismounter could be summoned for an assault; but if I were the magistrate, I should impose the smallest possible fine, as a bicyclist with a blazing torch is most certainly "within measurable distance" of a dangerous nuisance. Why does not the querist use a lamp—they are cheap enough? The above law makes *a lamp* compulsory; but it may be *a light* in some districts. Perhaps G. Newman's lamp failed, and he had to put up with a torch. I hope this was the case; as otherwise his exploit was just one of those foolish and dangerous tricks which bring discredit on all riders of the "steel steed."—B. H.

[52015.]—**Photometers.**—To Rev. T. E. Espin.—I am sorry that "Eta Orionis" has had so much trouble in making a photometer. On reading my description over again, it seemed possible to fall into the mistake which my querist seems to have made, and then, indeed, the prism would be of no use whatever. The passage runs "It consists of a prism placed behind one of the stops of the telescope. It is fastened into the tube of the telescope." What I should have said is that a hole is bored in the telescope tube just large enough to allow the prism to be inserted into the telescope Apex first, while the base is parallel with the tube of the telescope, and fills up the hole. The hole is bored near a stop, of which there are five in my telescope, so that it in no way interferes with the light from the object glass. The lamp of convex is placed outside the telescope close to the prism. "Eta Orionis" might make his prism, as I did mine, out of a thick piece of plate glass. If he can break off a corner neatly he will have all he requires. He will easily be able to tell if he has the right shape, for if he holds it to the sky base upwards at arms' length, and with the base parallel to his line of sight, he should see the sky reflected from the further side of the prism. If he still is unable to manage, and will write to me, I will do my best to help him; but I think he will find no further difficulty.—T. E. Espin.

[52016.]—**Depositing Platinum.**—"E. T. M." can paint his copper foil with a weak solution of platinic bichloride. Afterwards, the foil must be heated, to decompose the bichloride and leave a film of platinum.—Ressorp, F.C.S.

[52018.]—**Portable Engine—One Cylinder.**—I presume that your engine has only one eccentric, and consequently only runs one way. Now, if the valve has neither lap nor lead on steam side, the full throw of the eccentric will be vertically upwards when the crank is on its dead-centre. Therefore, if you place the eccentric with its full throw downwards, leaving the crank still on its dead-centre, the motion of your engine will be reversed; but if the valve has lap and lead, the eccentric will be further advanced. Hence, you must proceed as follows:—Make a mark at the extremity of the eccentric lineable with its full throw, then drop a vertical line cutting this mark. Now, unkey the eccentric and move it forwards until the mark is again cut by the vertical line. At this point the full throw of the eccentric is as much below the centre of crank shaft as it was before above it, which is all that is necessary to reverse the motion. The lead is the amount of opening that the valve gives for the admission of steam when the crank is on its centre, and is obtained by moving the eccentric forwards, the amount of which is determined by the size of the engine, &c.; but in your case you may give it $\frac{1}{16}$ of an inch.—Engineer, Dewsbury.

[52019.]—**Gas Engine.**—In reply to W. Ainsworth, the figures given on p. 224, Vol. XXXVII., were taken from the results of several trials of the engines, the quantity of gas used, power indicated and given out at the crankshaft being known, and from experience in the engines in daily work, and supported by the authority of Dr. Siemens, who stated at the Institute of Civil Engineers (*re* discussion on a paper by Mr. D. Clerk on the "Theory of the Gas Engine") that the fuel was burnt in a cylinder, which it was attempted to keep cool by passing water over it, and it was easy to conceive that the heat so generated was only partly utilised for maintaining the state of expansion of the heated gases, the cold sides of the cylinder taking a good half of it away at once, thus causing a great loss. Prof. A. W. B. Kennedy also said that he had had occasion to work out some gas engine indicator cards. Taking an indicator diagram of a 2 h.p. Otto engine, an average diagram from those taken at the Erfurt trials, and taking the quantity of gas, &c., given in the published results of those trials, he obtained the following results:—

	foot-lb.	per cent.
Mechanical equivalent of heat due to the complete combustion of the gas per (effective) stroke about................	11·000	
Work done per (effective) stroke about......................	2·050	18·6
Mechanical equivalent of heat discharged	3·250	29·5
Mechanical equivalent of heat not accounted for	5·700	51·9

From the judge's report on exhibits, Stockport Gas Apparatus Exhibition, 1882, Class 5, for the application of gas for motive power, trials as published in the *Journal of Gas Lighting*, Oct. 9, 1883, table 4:—

Name.	Nom. H.P.	Dynamometer.	Indicator.	Minutes required to consume 1 c. ft. of gas.	Units of work done 1 cubic foot of gas.
Otto	½	1·074	1·800	1·596	in clndr. 59·35 on flywhl. 37·48
„	6	—	10·600	0·283	in clndr. 70·17
Bisschop	¼	0·270	—	2·060	on flywhl. 13·200
„	½	0·520	—	0·617	on flywhl. 13·96

The ½ h.p. Otto at this trial was consuming at the rate of 38·35 cubic feet of gas per hour, 59·35 per cent. of which appears in the cylinder, or 23 cubic feet of gas, equal to 11,500,000ft.-lb. Of this the engine gave out by the dynamometer 1·074 h.p., or, in actual work, about 2,000,000ft.-lb. The other 9,500,000ft.-lb. must have passed away either by the exhaust or through the sides of the cylinder. The remaining 15·35 cubic ft. of gas was not burnt, but passed through the exhaust. Had this report given the temperature of the exhaust, and the number of revolutions, &c., we should then be able to calculate the exact quantity of heat carried away by the exhausting gases, which, being deducted from the 9,500,000ft.-lb., would show how much passed through the sides of the cold cylinder into the water jacket. See Minutes of Proceedings of the Institution of Civil Engineers, Vol. XCIX., Session 1881—2, Part 3.—R. A.

[52021.]—**Raising Lid of Iron Box.**—Would a weight same as used in window-sashes be of any use?—Watt.

[52023.]—**Apprentice's Overtime.**—You are bound by your indentures of apprenticeship to obey all lawful commands of your master, and if he, by the foreman, says you are to work overtime now, even though you have not been accustomed, you are bound to do so, unless there is a stipulation in the indentures to the contrary. He, not you, is to judge what is the wage to be paid. If you could give more particulars, I should be better able to answer your query.—G. Russell Pridham.

[52024.]—**Recovery of Sulphur.**—I cannot give a description of the plant required; but should think that the spent oxide need only be agitated with CS_2 in a covered vessel; then decanting the solution off into a retort, from which the CS_2 is subsequently distilled, leaving the sulphur behind. A low temperature must be used, and the distilled CS_2 may be condensed for further use. Could not the spent oxide be utilised for the manufacture of vitriol?—Ressorp, F.C.S.

[52028.]—**Wimshurst Influence Machine.**—I have made one in which the axle is made of ebonite, turned true. Each plate has a wooden cap cemented to it (with the cement sold for sticking glass, &c.), with a hole bored in for the axle. The caps must be turned flat, and the glass stuck on flat, else the plates will touch as they revolve. The plates are made to revolve in opposite directions by crossing one band.—Watt.

[52029.]—**Ebonite.**—You can flatten your plate by pouring hot water over it till it gets soft, and then clamping it between two flat boards till it is hard.—Watt.

[52030.]—**Photographic.**—Under the circumstances described (I speak from experience), I should say a yellow glass would answer every purpose, though as an additional precaution it might be advisable to have some sort of blind or curtain that could be drawn over the windows either in whole or in part, as the varying conditions of light may appear to render necessary.—W. Robinson, Jun.

[52030.]—**Photographic.**—I would strongly advise "Ruby," if he cannot get sufficient light to develop his negatives with, through ruby glass, to use a lamp. I have done this for some time past, and I find it answers very well; the lamp being really not half so troublesome to look after as one would think. Yellow glass, such as would be suitable to work wet collodion plates by, would completely spoil any dry plates.—Machina.

[52031.]—**Dynamo.**—The resistance of your armature should be about the same as field-magnets. The distance between the armature and field-magnets is too much; it should be as near as possible without touching.—Watt.

[52031.]—**Dynamo.**—From description, I think the wires must be connected up wrong. Wire from brush should go round first half of magnet, then cross, and go round other half in a contrary direction, thence to lamp, and back to remaining contact brush. It is difficult to say what is wrong without examining the machine; but if "Labor Omnia Vincit" fails to make it work, I shall be glad to help him if he will send me a sketch of machine and connections.—Light.

[52038.]—**Boiler.**—You will be no saver by reducing the pressure in your boiler from 70lb. to 30lb., but rather a loser. The proof is in the fact that a given weight of fuel will evaporate a given quantity of water, irrespective of its pressure or temperature. Therefore, it must be obvious to anyone, that steam at 70lb. will be drier than steam at 30lb., since to generate a given volume of steam less water will be required for that at 70lb. than that at 30lb.—Engineer, Dewsbury.

[52041.]—**Brush Dynamo Machine.**—I think Williams has connected up the coils of dynamo wrong, and the current in lower coil neutralises current in upper coil. Try connecting the inside end to outside end of opposite coils.—Light.

[52048.]—**Oxychloride of Mercury.**—The most simple test is that of volatilisation on heating—any residue indicates the probable presence of tin, bismuth, or lead. The bichloride is soluble in water, sulphuric ether, and rectified spirit. If "R. W. J." would like to know what impurities are present, I would readily examine his sample if he will advertise his address.—Ressorp, F.C.S.

[52048.]—**Oxychloride of Mercury.**—All combinations of mercury with *volatile* acids are entirely dissipated by heat. There are three chlorides of mercury found in commerce—viz., "calomel," or mercurous chloride; "corrosive sublimate," or mercuric chloride; and "white precipitate," which is mercuric ammonio-chloride. I suppose "R. W. I." refers to one of these; however, they are all entirely volatilised below a red heat, and a residue would certainly be an impurity.—W. E. Haden.

[52051.]—**N.B.R. Locos.**—As this query has been answered before, I will only give a few principal dimensions of these bogie express engines:—Diameter of cylinder 18in.; length of stroke, 26in. diameter of four-coupled wheels, 6ft. 6in.; total heating surface, 1,100 sq. ft.; weight of engine, 44 tons; water capacity of tender, 2,400 gallons. There are 12 of these engines, four being stationed at Glasgow, Edinburgh, and Carlisle respectively. Concerning the single engines, "Glasgow" and "Berwick," about which a query appeared on the 5th, I can only say their cylinders are the same size as the bogies, and their driving wheels are 7ft. in diameter.—W. Thompson.

[52051.]—**North British Engines.**—The North British Company's coupled bogie express engines, which convey the Midland Scotch Joint Stock trains between Carlisle and Edinburgh, were designed by Mr. Drummond. They have cylinders 18in. diameter, with 26in. stroke, and as the wheels are 6ft. 6in. diameter, the tractive force is thus

$$\frac{18^2 \times 26}{78} = 108\text{lb.}$$

or 108lb. exerted for each pound of effective pressure per square inch upon the pistons. The engines are all fitted with the Westinghouse brake. It may be mentioned that the Glasgow and South Western Company has also some powerful express engines to convey the Glasgow portions of the same trains between Carlisle and Glasgow.—Clement E. Stretton.

[52054.]—**To "Vulcanite."**—All the questions asked in this query are explained and answered in the book I named in my reply to 51346 on 14th September.—Vulcanite.

[52054.]—**Flute.**—The proper places of side holes on a flute depend upon so many "fine points," and would take up so much space, that I must advise "Constant Reader" either to wait until "Vulcanite" arrives at that point, or obtain the book before alluded to (see page 42). Opinions differ as to which is the best—the cylinder, or the taper bore. Boehm, the great flautist and flute maker, believed in a cylinder bore, with parabolic head joint. I am sorry I cannot help "C. R." to the best form of tool for taper-boring; but, for a cylinder bore, I have pleasure in recommending him to the article by Mr. Evans in this our valuable paper, Vol. XXXIII. No. 848, page 368.—Old Blow Hard.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list and send what information they can for the benefit of their fellow contributors.

QUERIES.

[52060.]—**To "Fellow-Workman."**—I had a mainspring to put into a lever watch the other day, and succeeded in putting it in with my fingers—after some failures—and after having my fingers severely scored and blistered. I believe there is a machine for doing this work, and would be glad if you would inform me how to use it after I get it, and if the spring is wound direct into the barrel, or how? Just before this I had another lever with a broken hairspring—a coil wanting—watch spring above. I got roller and rolled off all right and new spring on, in all respects as nearly like the old spring as possible, only with full number of coils. Spring was perfectly flat and free all round, and tight on collet, yet when balance was put in, watch would not keep going: seemed to me as if the spring itself had brought the wheel to a stand. I could not see what was wrong and gave it up. Do you think you could point out where I had gone wrong, and earn the gratitude of—Scotus.

[52061.]—**Medical.**—For some weeks I have been suffering in my ear. It first inflamed and was very painful. Then a discharge commenced, and the pain subsided. Our family doctor instructed me to syringe it with warm water and drop in tannate of glycerine. He now tells me that there is a growth in the meatus very near to the tympanum. This I suppose is polypus. He dug some of it out, and told me that if it should not be better in a few days he would send me to an aurist. I believe these things are often very difficult to get rid of. I shall be glad to know if there is any method of curing polypus, except by surgical operation. Is there any solvent or drug that will destroy the fungus? I have read that sulphur is inimical to every form of fungus life, and that it has been used, as a gargle, successfully, in cases of diphtheria. I shall be very much obliged for advice, as bathing and injecting two or three times a day is very inconvenient, to say nothing of the pain, which is sometimes severe. I may say that I am otherwise in good health.—Salvo Jure.

[52062.]—**End Bearing for High-Speed Spindle.**—An upright spindle of hardened steel, ⅜in. diam., with a rounded end at bottom, bears on the end of a hardened steel plug, which is similarly rounded, and a well of thin machine oil surrounds the bearing. The weight supported by the bearing is about 40lb., and the speed of the spindle is 7,000 per minute. The bearing is unsatisfactory, as the surfaces heat and tear each other somewhat, the spindle remaining roughly convex, while, the end of plug becomes concave. I think the oil is forced away from the bearing by the pressure and the high speed. Would matters be improved by using different metals for the bearing by altering the shape of the surfaces in contact, or by employing a thicker oil such as vaseline? The bearing surfaces are very hard, and are immersed in the oil.—Centrifugal.

[52063.]—**Feed-Pump.**—What pressure would there be in a pump working at 150 strokes per minute, with a boiler pressure of 130lb. per square inch, the diameter of the ram 2in., stroke 24in., diameter of feed-valve 2¼in., diameter of delivery-valve 2½in., supposing the pump to be ¾ full at each stroke?—Pressure.

[52064.]—**Exhaust.**—Can anyone give me a simple rule for finding what distance the piston has travelled when the slide-valve opens to exhaust? I cannot work out the rule given in Molesworth, as I cannot do trigonometry.—Pressure.

[52065.]—**Dulling Nickel Plate.**—Can any tell me how to dull a nickel-plated article, so as it of a dead blue or black colour? I fancy the acid, or mixture of acids, which will effect this. Graph.

[52066.]—**Brazing.**—Can anyone inform m modus operandi of brazing with atmospheric gas? made a fan and connected it with the gas by m ½in. indiarubber tube, but cannot get sufficient special burner required? I am making a tricycle, and several parts must be brazed on frame which I cannot get on the forge.—Cyclist.

[52067.]—**Paint for Tin Pots.**—Can anyone tell me of a good, durable, elastic paint or varnish for the purpose of coating ordinary tins with, so as to prevent their being corroded by the action of saline solutions even after continued use? It is of great impertance that it should adhere firmly, not be troublesome to use, and not expensive. Have tried a mixture of pitch, paraffin, and marine glue, but it becomes soft, buckles up, and is liable to be scratched off.—P.

[52068.]—**Fairy Lamps.**—Can any correspondent tell me from what source the fairy lamps in theatres are lighted—whether from a small secondary or primary battery?—and what metals are the elements?—P. Y. C.

[52069.]—**Metropolitan Building Act**—Does section 92 give a building owner who has paid the whole cost of a party wall, an absolute lien on it, so as to enable him to make the landlord of the adjoining house pay his tenant's share of, or to get same from a new incoming tenant? I have rebuilt my house, which I will call 40, Blank-street, and the party wall between my house and No. 30 being very defective and out of upright, has had to be rebuilt from including the foundation, and I have paid for the whole of the work, having been unable to get anything out of B., the owner of No. 30. B. has since failed, the estate showing, practically, no assets, and his house is now taken by C., who is making alterations, which evidently involve cutting the wall about, as brick and cement rubbish, is being carted away. Can I stop C. doing anything to the wall until he has paid B.'s share of its cost? The exact amount for which B. was liable is not yet settled, as the arbitrator has not given in his award.—Horloger.

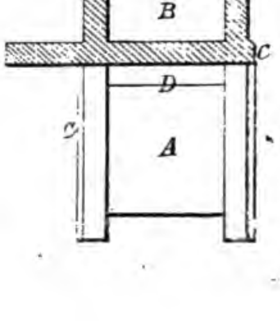
[52070.]—**To "F.R.A.S."**—Is δ (delta) Cygni a good test for 4½in. achr.? I split it perfectly in moonlight, and find the colours well contrasted.—C. J. R. Ventor.

[52071.]—**To "F.R.A.S."**—(1) Must we infer from the presence of chipped flints in the Brixham caverns, either that human beings lived in those cavities together with the bears and hyænas, or that the flints were carried thither by those animals after being wounded by them? (2) Could a jagged flint be forced by human hands through the thick skin of a bear? (3) Is it unreasonable to suppose that the flints were caught up by the hair of the prey of the bears and hyænas as they were being dragged to the caverns over ground strewed with flints? (4) If flints did thus attach themselves to the animals that were devoured, would they not sometimes be "crunched" by the devouring animals, and would not the strong jaws of the hyæna break them into smaller pieces than would those of the bear?—and would not this account for the difference in size between the flints in the upper and lower layers of the Brixham cave?—K.

[52072.]—**Crayfish—Where and When to be Found.**—Some months ago, a correspondent told us in your best of science magazines that in early autumn those agreeable little pseudo-lobsters, crayfish, were to be found in every rivulet of running water, brook, and river. Alas, Sir, in what region of the blessed are these fertile waters to be found? I am living in North Devon, amidst trout-full streams, grilse-teeming floods, and salmon-visited noble rivers, yet never did I see a single specimen of a crayfish in these waters. Why?—R. Enis.

[52073.]—**Penang.**—Will some of ours kindly give me any information they can, respecting the above island as to climate, cost of living, kind of clothing required, &c.? The names of any works on this subject will oblige.—Am Emigrant Teacher.

[52074.]—**Lathe.**—(1) Can any of your readers help me in making a pattern of a lathe bed? The only way that I know of, is to make the pattern solid and have core boxes. The trouble principally is the border C round the bottom edges, the recess B, and the webs A on each side of the gap. B is for the bolts to screw the standards (German pattern) on with. The lathe is a 5½in. centre screw-cutting gap bed lathe, and intended to turn 24in. diam.; and I wish to know how thick the bed should be—would ¼th be enough? The bed is over 5ft. long, and to avoid a long crankshaft the standards are placed 4ft. apart, the bed overhanging about 20in. or more. Therefore, the shaded portion in the sketch occurs again, 4ft. from the mandrel end, and that adds to the trouble. The line D is the bottom of the gap. The



wi.h to

protection order), without the husband's receipt? The testator died last year.—Dubious.

[52 76.]—**Wood Pulp.**—How can I make wood shavings and cuttings into a soft pulp?—Paper.

[52077.]—**Machine Drawing.**—Will any correspondent (one who has undergone examination, if possible) oblige me by giving me a few hints about practising machine drawing for the Advanced stage of the Science and Art Department Examinations in machine construction and drawing? I have the knowledge of machine details required, I believe, and I have copied a few working drawings of machines; but the dimensioned sketches of the examinations I could not, when in the room, manage properly. Please do not refer me to Maxton, as I have read it. What I seem to want is practice; but I do not know how to go about it.—Engineering Student.

[52078.]—**Granule Battery.**—I should be glad if any subscriber could tell me if the old crushed carbon in the above cell can be used again for recharging the cell, as I find it expensive to recharge always with new?—P. Y. C.

[52079.]—**Watercloset**—Would any of the readers of your valuable journal kindly assist me in the following?—I took a house a few months ago, in which there are two w.c.'s worked by a force-pump. All are out of order, and have been for some time On examining the soilpipe from w.c.'s, I find there are small irregular holes in it, extending at intervals throughout most of it and all on one side. Can they be caused by corrosion or by rats, as there are traces of them? I have been recommended to put glazed sewerage tile pipes in lieu of the old lead one, which is from 26 to 30ft. in length;—would the former last long, and what would be the probable cost of them? I wish to try and repair all with the aid of a good carpenter, as plumber's charges to come here would be exorbitant. I should be glad of the name of any book that would give me intelligible instruction on the above subject.—Aqua.

[52080.]—**Water Main.**—Our waterworks are about to supply a small village about three miles from works. It is proposed to make connection close to pumps on a 20in. pipe, by taking out one pipe and putting another in its place, with a connection and valve, so as we can send water to them when required. Will any of our readers tell me how to proceed to take pipe out and put another in its place?—must I take sledge and break pipe, and must the new pipe be shorter than the one taken out?—if any, how much?—Turncock.

[52081.]—**Marks on Silver Plate, &c.**—Can any correspondent inform me what is the difference, if any, in the fineness of silver jewellery sold as (1) fine silver. (2) real silver. (3) sterling silver. (4) standard silver? And also whether the mark of "a lion passant" is the mark of the best quality of silver?—J. H.

[52082.]—**Contents of Box.**—To. "St. Aubyns" and Others.—A sack measuring 5ft. 1in. in circumference and 3ft. 6in. in length, will hold, when full, 18 stones weight of wheat (14lb to the stone). Wanted to know, of what height must an oblong box be made, being 2ft. 11in. long by 2ft. 6in wide, and having the whole of the bottom sloping longway in from back to front at an angle of 40°, to hold the same quantity of wheat?—Contra.

[52083.]—**Punching Machine.**—Having seen the other day a large punching and shearing machine at work, I wondered how the makers arrived at the pressure required to punch a certain plate. Now the hole which I saw punched was 2in., and the thickness of the plate, which was of steel, 2in. What pressure in tons wou'd it require, and how is the calculation made?—Crado.

[52084.]—**Building Society.**—Would the committee of a building society have power to impose continued subscriptions after a borrowed share had attained its full value, in order to create a surplus fund, nothing to that effect being in the printed rules furnished to the members at the time of joining the society?—Working Man.

[52085.]—**Building Society.**—I am a borrowing member of a building society, the shares of which are £60, for which I have to pay £3 per annum as subscriptions, and £3 as interest, and 3s. 6d. expense fund per annum. I should be glad to know how many years I have to pay the subscriptions and interest before the property would be clear of the mortgage, and the shares realise the value of £60. If there is a rule how to calculate same, should feel much obliged if some subscriber would kindly give it.—Working Man.

[52086.]—**Learning the Zither.**—Will some reader kindly say if this instrument is a difficult one to master, and if it can be learnt by the aid of an instruction book only?—Ignoramus.

[52087.]—**Pressure on Crank Pin.**—Would "Engineer, Dewsbury," or "Firer, Dewsbury," kindly help me with the following?—What will be the pressure on the crank-pin of our Macnaughted beam engine, when the crank has moved through an arc of 45° from the top centre? The effective pressure in the h.p. cylinder at this point is 62lb. per square inch, and in the l.p. cylinder 18lb. per square inch. Diameter of h.p. cylinder = 18½in. by 2½ft. stroke, and the l.p. cylinder = 25in. diameter by 5ft. stroke. Revolutions per minute 40. The weight of the transmitting parts is, say, four tons.—H. N.

[52088.]—**Black Stain.**—Will any of ours kindly oblige a constant subscriber with a permanent black stain for cork wood that will withstand hot or cold water?—Cork Wood.

[52089.]—**Frosting Tin Tubes.**—By what process is a frosted or crystalline appearance given to tin tubes, such as are used in kaleidoscopes and other instruments?—P. M.

[52090.]—**Telegraph Instrument.**—Having con- [illegible]ted and fixed a set of small telegraph instruments— [illegible] of simple key transmitters, and a pair of [illegible]dle instruments, the way I have them con- [illegible] one of the keys is only the distant [illegible]d of both the needle instruments [illegible]der may see what he is sending. [illegible]m on the latter plan (no earth [illegible]nt Subscriber and Reader.

[52091.—**Engine Query.**—How can I know when an inverted cylinder engine is at rest (with and without reversing gear), which way the shaft will revolve when the steam is applied? A little explanation on the subject will be thankfully received. Please do not refer me to back numbers.—L. M. B.

[52092.]—**Lake Strangford.**—What is the superficial area, in acres, of Lake Strangford in Ireland?—also of the Zuyder-Zee in Holland?—A. Z.

[52093.]—**Load on Columns or Stanchions.**—The formulæ for calculating the above suppose that the pressure passes down the axis, or that the pressure is symmetrically distributed over the sectional area. But in practice this is not always the case. What correction should be made when the pressure passes down a line at any distance from the axis?—J. S. C.

[52094.]—**Lost Watch Wheel.**—To "R. E. D."—Many thanks for your reply to my query. I would also ask you what sort of acid is used for dipping any article into after hard soldering? Again, what is the reason of a clock going fast when it is newly wound up, then slow, when it has run about five days?—seven-days going barrel. Is mainspring at fault?—Hall.

[52095.]—**The Vienna Refractor.**—Have any particulars been published of the performance of Grubb's 27in. refractor? By this time something should be known as to its merits. Perhaps some of "ours" can enlighten me. I should also be glad to know whether there is anywhere published a list of the leading telescopes now in use in the principal observatories, giving the aperture and focus of each, together with the makers' names.—Achromatic.

[52096.]—**Vibrations of a Magnetic Needle.**—A magnetic needle balanced horizontally at its centre upon a firm point, makes 11 vibrations in 2 minutes 1 second at a place A, and 12 vibrations in 2 minutes at a place B. Compare the strength of the earth's horizontal magnetic force at the two places, explaining clearly how you arrive at the result?—W. S.

[52097.]—**Vibrations of a Magnetic Needle.**—A small magnetic needle suspended horizontally by a silk fibre makes 100 vibrations in 5 minutes 36 seconds, under the influence of the earth's magnetism only, and 100 vibrations in 4 minutes 54 seconds when a horizontal bar magnet is placed with its centre vertically below the needle, and with its axis in the magnetic meridian. Compare the magnetic force exerted upon the needle by the bar magnet when in this position, with that exerted upon the needle by the earth?—W. S.

[52098.]—**The Torsion Balance.**—Two straight pieces, one 3in. and the other 5in. long, are cut from the same narrow strip of steel. After being equally magnetised, they are hung horizontally, one at a time, by the same fine glass thread, so as to rest in the magnetic meridian when the glass thread is not twisted. On turning the upper end of the thread half-way round (through 180°) the shorter magnet is deflected ten degrees from the meridian. Show how much the upper end of the thread must be turned to deflect the longer magnet ten degrees?—W. S.

[52099.]—**Agricultural.**—Thanks to "Farmer." Will he now kindly give me the value of permanent pasture—that is, what sum an outgoing tenant, who has laid down permanent pasture fairly well, ought to receive from his landlord as compensation, that compensation being, I should say, the increased value of the land to the incoming tenant? I think the average mangold crop in Hants (South), would scarcely be so much as 30 tons per acre, but that the average price per ton would be £1, that is in heap.—Estate Agent.

[52100.]—**Electrical.**—(1) Will someone who thoroughly understands batteries, say if a one-cell quart, half-full, bichromate battery, three carbons and two zincs, each 2in. square, would render the platinum wire of a lamp to be lighted by electricity, incandescent?—and if so how long would the solution last, the zinc being withdrawn except when pressed into the cell to generate the current, and only used, say, once a day? (2) Would two carbons and one zinc, same size as above, do the work required, conditions as above?—R. Hannen.

[52101.]—**Induction Coils.**—Will any reader kindly answer the following questions? (1) Would the power obtained from a coil containing 1,000yd. of No. 3? silk-covered wire be as great as or less than one containing the same quantity of No. 38? (2) How many five-plate cells of a bichromate battery would be required to obtain the full power of the coil of No. 38 wire, as described above, the carbons being 7in. × 3½in. × ¼in.? (3) I want to place a water regulator horizontally in the inside of a coil and have a vertical contact-breaker, and have the connections the same as the contact-breaker, with the iron bundle for the magnet. Will this answer? (4) Is it necessary to have a bundle of wires in the coil if it will?—Invicta.

[52102.]—**To "F.R.A.S.," Mr. Holmes, or Other Astro. Friend.**—A series of popular papers, suggestions, or hints on the construction, mounting, and mode of using a handy but efficient form of a student's equatorial would be appreciated, I am sure, by many of our amateurs. The price usually charged by opticians is too often prohibitive. I feel sure, to many of limited means full description, with drawing of "divided circles," suitable to a 3in. or 4in. aperture, with directions for setting them on the instrument, would no doubt enable many an amateur to provide himself at little cost with this useful, and in some cases necessary, appendage for practical astro. work—Vigilans.

[52103.]—**Engine.**—Would "Engineer, Dewsbury," or "Labor Omnia Vincit," help me out with the following? If steam at 60lb. by gauge is used in a compound engine, and each cut-off is at half-stroke, the low-pressure cylinder being four times the volume of the high-pressure one: required the pressure of steam at points of cut-off, final pressure, and back pressure, and also the number of expansions, and what part of stroke must I cut steam off in a single-cylinder engine to get the same number of expansions as in compound engine? Vacuum by gauge 13lb.—Young Enginesman.

[52104.]—**Removing Veneer.**—Will any reader give me a little help with the following job? I have part of the frame of an old piano which is veneered or laid with walnut. This I wish to remove so as to use it again; but I wish to get it off bodily without damaging the face—which is very smooth and glossy. How must I proceed?—Engineer, Dewsbury.

[52105.]—**Cutting Circular Glasses for Chromatropes.**—Can any reader tell me of a simple method of cutting glass for the above?—Chemicus.

[52106.]—**Jacquard Loom.**—Will any reader kindly tell me if there is a jacquard loom which weaves the weft in a circular manner across the warp—i.e., instead of of lying straight across, it is made to be, say, 2in. or so nearer the beam in the centre than at the two edges? If there is not, could such a thing be done, and by what means could it? Is there any book to be had which might give me the desired information?—J. A. S.

[52107.]—**Toning Bath.**—I purchased a bath containing sufficient chloride of gold to tone eight sheets of paper. After once or twice using I find I cannot get a good colour in toning—only a dirty brown tint. How can I alter this? How long should prints take to tone as a rule? My last have been in 8 or 10 hours, and then are not really a good colour.—Dozey G.

[52108.]—**Integral.**—Will some reader kindly show me the method of obtaining the general integral of the equation—

$$\frac{dy}{dx} = \frac{d^2u}{dx^2} = \frac{u}{a^2}$$

Rankine states it to be—

$$a = Ae^{\frac{x}{a}} - Be^{-\frac{x}{a}}$$

("App. Mech.," p. 175).—Vis Viva.

[52109.]—**Lathe.**—Will "Nun Dor.," "Os," or some of our practical readers kindly instruct me how to fit a pair of 3½in. centre back-geared lathe heads up? I am a poor man, and cannot afford to send them to a first-class fitting shop. How is the gear-wheel made fast to mandrel, and what diameter of thread should I have on the mandrel nose? All particulars how to fit the above up will oblige.—Miner.

[52110.]—**Mangle Rollers.**—Will some kind reader inform me how to select wood, turn, and fit spindles to mangle rollers?—Iron.

[52111.]—**Drilling up Balance Staffs and Pinions without Softening them.**—Is it possible to drill up an English balance staff or pinion without softening them? I have been told such can be done; but although I have made drills of the best steel, I cannot do it. I should like to know if it is usual in the trade, as it appears to me to be impossible, since all the staffs and pinions I have come across that were pivoted were softened.—Hard Steel.

[52112.]—**The Sun's Distance.**—I find from a textbook on astronomy that the apparent diameter of the earth when nearest to, and seen from, the sun is 17·86". Can this be ascertained without first knowing the sun's distance, and if so, could not the sun's distance be found with considerable accuracy by finding (thus $\frac{360°}{17·86''}$) the number of earths it would take to form a ring round the sun at the distance of the earth when nearest to it? This number, multiplied by the earth's real diameter and divided by 2π would furnish in miles the distance of the sun when the earth is in perihelion. The result, using the earth's equatorial diameter, is 91,545,478 miles nearly. If, on the other hand, the knowledge of the approximate distance of the sun is required in order to calculate the apparent diameter of the earth as seen from the sun, could not this method be used to find, more accurately than has hitherto been done, the distance of a planet—as seen from which the apparent diameter of the earth can be calculated, irrespectively of knowing the planet's distance,—and then this distance be used as a base line for finding the sun's distance? Information on these points will be gratefully received by—A Young Star-Gazer.

[52113.]—**Magnetism.**—Will some of your readers kindly work out the following? A mariner's compass is placed on a table and a bar magnet is laid on the floor below it, the centre of the bar magnet being straight underneath the centre of the compass needle. When the N.-seeking end of the bar magnet is northwards, the compass needle, after being disturbed, makes 100 oscillations in 16 minutes. When the N.-seeking end is southwards the compass needle makes 100 oscillations in 12 minutes. When the magnet is removed, so that the compass needle oscillates under the influence of the earth alone, how long will it take to make 100 oscillations?—Young Student.

[52114.]—**Painting Windows in Oil.**—Is there any means by which a window can be painted in really transparent oil colours? Would varnish answer as a medium, and if so, what varnish? I have tried Judson's dyes in water-glass, but find the mixture, from some reason, spoil the colour—magenta becoming a muddy reddish purple.—Achespe.

[52115.]—**Bramah's Press.**—Can any correspondent tell me what tubes are most used to convey steam into the plates of a Bramah's press when used for finishing textile fabric? I now use indiarubber and canvas. I have heard of flexible copper tubes being used. I should like to know how attached and where they are to be got? Please send sketch of attachment.—Subscriber.

[52116.]—**Legal.**—(1) When a person buys a business from another, but takes the house at quarter-day, is he responsible for the poor, gas, or water rates if the former tenant left them unpaid? If so, can he sue the former tenant for them? (2) What is the correct proceeding to take when a lodger does not pay his rent, and you want your money?—T. A. R. T.

[52117.]—**Legal.**—B. dies in Cape Colony, and leaves L. and her family all his possessions, which are both fixed and movable. Before B. died he made a will and entered it in the High Court of the Colony and an executrix to communicate with L. How long can she keep the movables before sending them to L., or can she dispose of any property without consulting L.? She has a percentage on all money that comes to L.—A Constant Reader.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* Editor *of the* English Mechanic, 31, *Tavistock-street, Covent Garden, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, Oct. 24, and unacknowledged elsewhere:—

Blakey, Emmott and Co.—W. Wright.—Edmund Broderip.—T. Trower.—J. and W. E. Archbutt.—Rev. S. R. Craig.—Castor.—Volt.—A. R. Wilkinson.—W. B. P.—G. Hartley.—James Edwards.—London River.—W. H. Richmond.—T. B.—Practical Chemist.—E. B. Fennessy.—Lincoln.—G. D. Goold.—Hemisphere.—W. A. Felton.—R. J. Walsh.—R. Bolton.—Markwell.—Ivanhoe.—A. V. Nicholls.—Inexperienced.—J. I. S.—Ixion.—E. R. D.—Colonial Collier.—Rev. J. J. M. Parry.—A Seven Years' Subscriber.—W. Limont.—Platinum.—C. Gandibert.—Vulcanite.—H.—G. A.

M. Piper. (Impossible to explain first query without knowing connections. 2. Pitch, treacle, sugar, rosin, and other carbonaceous substances.)—Mechanic. (Frequently answered. Harmonium reeds cannot be used in the tubes of an American organ, and are not advisable in any suction instrument.)—Ebo. (A magnet will operate the tap, and a coil of platinum wire rendered incandescent, or a spark passed between two points, will light the gas. See indices. 2. Pieces of wire soldered in.)—Stargazer. (Very doubtful. It depends on the quality of the o.g. An optician would tell you in a moment after inspecting it.)—Paddy. (Illustrations of two sledges on pp. 333, 337, Vol. XXXIV.)—Anxious Inquirer. (Procure Bagster's list, and the catalogues of other publishers.)—Invicta. (They are sure to fade in light to a certain extent; but they might be preserved by varnishing.)—J. Harris. (Use iodide of potassium. See any handbook of the art.)—A Weary One. (We know of nothing better than soft water and good soap.)—J. P. R. (The specimen sent leaves rather more red stuff on the paper than is pleasant, and is scarcely efficient as an eraser. Warmth would soften it temporarily; but we are afraid your stock is useless, except for reworking at the factory.)—Dark Blue. (Properly, black sulphur is the crude native sulphur; but refuse from the subliming pots is often substituted for it. The latter is poisonous from the quantity of arsenic it often contains.)—Aurora. (We thought quite enough had been heard of the experiments. There is nothing special in the motor, which is a common form. Any results which may be superior are produced by the method of winding and by the construction of the magnets; but the question is whether any superior results have been obtained.)—Leo. (Similar questions have been answered many times, with illustrations. See the indices, and read the present series of papers.)—W. H. C. (There is nothing very special in the method. Prepare the foundation with broken brick, &c., and then put on a layer of small gravel stones coated with tar. These stones are first thoroughly washed, and then coated with tar, which has been boiled to evaporate all the water. This layer is rolled down, and is then floated with a coat of hot tar, which is covered with sand or chips of fluorspar and rolled.)—Amateur Smith. (There are several methods in back volumes. Coat with borax or plaster of Paris to weld, and dip when at a red heat into salt and water to harden.)—T. H. (There is no book on the subject, and it is almost a lost art. The shell is joined by heating, and the smoothing and polishing done in the ordinary way, with glasspaper and crocus or rouge.)—Plasterer. (See p. 445, Vol. XXXVI., and the indices generally.)—Sol Fah. (Procure one of Novello's catalogues. The address is Berners-street, W.C., and you will find several works on the subject. Don't practise with set pieces; but exercise, whenever convenient, with the simple scale, keeping well within your limits. You will thus strengthen and improve the voice, and the rest will come in due course. If you have not patience for that, you may ruin it.)—S. L. W. (If it is ordinary putty, it will soon yield to a strong solution of caustic potash applied with an old brush. Mind your fingers. If the putty is a mixture of white and red lead, it will take longer to soften it.)—Amateur. (If you will say what you mean by a "solution of *the* salt of gold," we shall be able to tell you. Which salt do you mean?)—A Lover of Ours. (Read up what has been said in back numbers about small dynamos. It is impossible for us to find room for all the queries which reach us from those who are anxious to make small dynamos and motors without having even an idea of the construction.)—Cam. (Most of the publishers who issue educational works can supply you. There is a cheap work of the kind in Collins' Advanced Series.)—J. C., Ten Years' Reader. (Rock-salt will kill weeds, if you apply enough; but you would find a strong solution of sulphuric acid more useful.)—Plater. (It was described at length by Mr. Sprague on pp. 1, 45, last volume. There is no better battery than a Daniell for general electro-metallurgy; but the Smee cell is sometimes preferred.)—Porridge Pan. (Use something like a gluepot, one vessel inside another.)—M. A. S. (No; there is no obligation to accept a lowest tender.)—Subscriber. (The family name of the Queen is generally said to be Guelph.)—Rev. S. Mills. (It is not so bad as all that, and we cannot spare the space to repeat. If you and other astronomical correspondents would kindly make your diagrams black upon white, and not white on black, just like the second diagram sent, there would be no difficulty. The difficulty is as much in the working as in the engraving. The "E.M." is necessarily printed rapidly, and small spots in the middle of a dark field soon fill—some readers, of course, getting better-printed copies than others.)—C. Wood. (Printed copies of all published specifications can be bought at the Government Patent Office, Southampton-buildings.)—Joseph Seel. (We could not spare space, or avail ourselves of the arrangement suggested.)—J. McD. (We should sue them in the County-court for the sum paid.)—Pearl. (We cannot go into commercial matters.)—Baritone. (Neither indulgence improves the voice.)—Longfield. (1. Occasionally missing the draught would not matter much. 2. A very common thing, and not at all due to the cause mentioned.)—A. Stanley Williams. (Thanks, but we have not room this week, and next it will be too late.)—H. B. Flockton. (If practical, and not too long, we could publish them.)—John Hampden. (Not a bad idea; but a general invitation would bring so many suggestions from people ignorant of what had already been attempted, that we should tremble for our space. Have you ever had to search at the Patent Office yourself? If so, you must have been struck with the numerous abandoned inventions in various branches of manufacture of which you were previously ignorant.)—G. M.—(For information about goitre, or Derbyshire neck, see pp. 271, 340, 390, 463, 539, Vol. XVIII.)—Science. (Procure catalogues from Macmillan and other publishers. You do not specify the district.)—Aeronaut. (The cheapest method is to pass steam through a tube containing red-hot iron borings. Calico would do if treated with suitable varnishing coats, but silk is better.)—S. T. J. (See p. 120, Vol. XXXIV., and the indices generally. The water ought not to boil at all, but to circulate as soon as it becomes hot. Mr. Eldridge, 54, Murray-street, Hoxton, N., publishes a guide.)—An Anxious Parent. (See Dr. Edmunds's remedy on p. 430, No. 903. See also pp. 562, 583, 607, Vol. XXVI.)—Amateur Beekeeper. (You should procure one of the cheap handbooks on the subject—say Rusbridge's, published by Allen, Ave Maria-lane, E.C., 1s. 6d.; or look up the subject in back volumes. All sorts of devices have been described.)—John R. Rhodes. (See p. 289, Vol. XXXVI. The weight that must be carried is too great, and as an "auxiliary" would be altogether out of place.)—Oswald Twistle. (It is impossible for us to discover which articles you mean by the simple reference "a good while ago." Perhaps you mean the article on p. 353, No. 926.)—Economist. (If we understand you, the only way is to obtain a proper portrait lens. A good deal can be done by lighting the sitter, and if you have a Merveilleux, you ought to have no difficulty in making very good portraits indeed.)—Indefatigable. (Both queries answered many times. For full instructions in French polishing see pp. 175, 227, Vol. XXXII., and the indices generally for many references. 2. It is spread on tinfoil, and the perfectly clean glass slid on and weighted down.)—Iron. (The "spelter" is a softer brass than the parts to be joined. See back numbers for full directions in brazing. 2. For grinding skates, see p. 16, No. 833; p. 527, No. 828.)—A Sufferer (P'boro). (Dr. Edmunds has replied at length; see p. 209, No. 919.)—Tinteretto. (Leclanché, if you want them for such work as bell-ringing; but if for power, Bunsen. 2. The best soft iron rod will do; but it should always be made red-hot, and allowed to cool very slowly. 3. Sprague's "Electricity" (Spons); new edition coming out "soon" or "shortly.")—Tempo. (The aneroid barometer is described in many textbooks and cyclopædias. Such records have been kept for years, but we do not know what use they have been.)—Sapo. (There is one by Ott, and Messrs. Lockwood have one in the press. You will find articles in back volumes. and in the cyclopædias; but the trade is much of a secret in all important details.)—T. W. K. (If you cannot find one in all those volumes, we should advise you to look at some of those sold by the seedsmen.)—Ironmonger. (See indices of recent volumes, and the articles now appearing. No machine yet invented does more work than is put into it. How could it?)—Snowdrop. (Your query is incomprehensible.)—F. W. B. (If the facts are as you state, you are a tenant from year to year, and your landlady must give you six months' notice, terminating at the time at which you took the house, before she can raise your rent or turn you out. If you have failed to keep the premises in proper repair, she must take other steps; she cannot summarily raise the rent in the manner you mention.)—W. A. (Illegitimacy does not in any way affect a man's capacity to make a will.)—W. S. (We really cannot understand the query, and you had better consult a solicitor. Most probably the son and grandson will share equally.)—Boz. (You can recover if the accident was caused by the butcher's negligence or that of his servants.)—Spec. (If the "company" is not limited, an ordinary partnership agreement would suffice. We cannot advise further.)—Cymro. (Slates cannot be tested in the way you suppose. Judgment and experience are necessary in estimating durability.)—F. G. (In type.)

Every Workman connected with the Building Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 31, Tavistock-street, Covent-garden, London, W.C.

"THE BUILDING NEWS" is the Principal Journal, representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is One Shilling for Twenty-four Words, and Sixpence for every Eight Words after.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
FRIDAY, NOVEMBER 2, 1883.

A FEW HINTS ON CARPENTRY.—II.

IN the last brief paper I promised to give directions for putting shelves together without nails, which do not make either the best or strongest joint. If they *are* used, it is better to insert them alternately to right and left, so that they shall not follow exactly the direction of the grain where they go into the ends of the shelves. Wire nails driven straight down into the end of a deal board have not much hold, although I am aware that some think them better than ordinary wrought-iron nails, because the latter are wedge-shaped, and, therefore, if drawn out a little way become (so it is argued) loose from end to end. But in reality, the angle of the wedge is very small, and the nails only taper in one direction, two of their sides being parallel, and the roughness of the iron acts like a set of teeth in giving them holding power, while the wire nails are smooth. The heads of wire nails, too, are not easily driven below the surface, while a clasp nail may be readily imbedded, and itself acts as an additional holdfast. Screws, again, are no use in the end of a deal board; they will draw straight out, bringing with them the fibres immediately surrounding them, and leaving a cylindrical hole. By far the neatest plan for oak shelves is the wedge driven through the tenon and left outside, and it has this additional advantage, that it can be knocked out, leaving the shelves and sides as plain flat boards, which can be readily packed for removal if required. Deal shelves can also be thus made if sufficient length of tenon is left to prevent the wedge from splitting out the stuff; but there is no sort of comparison between deal and oak, though the former be painted, or grained, or varnished; and though the cost of the stuff is a little higher, I would always recommend oak, and oak alone, for study shelves and fittings. But oak is a generic name of a certain kind of tree, and for home operations especially the ordinary English oak is most untractable. Stave oak is the stuff, such as barrels are made of. I believe it is of American growth; at any rate, it is straight grained, easily planed, and pleasant to work. I had, lying about, some blackened old cask staves doomed to be burned; but the other day, wanting a bit of oak for another purpose, I made use of a piece of this waste material, and it was so dry and so pleasant to work that I hunted up some more out of the wood pile, and made a bracket for the hall out of it, and very satisfactory it proved. I give a sketch, as it is rather a nice pattern, and will hold a small flowerpot. The shelf with chamfered edge is a bit of the top of the cask. The size was limited, as the cask was small, and the staves therefore much curved; but staves from any large cask will afford several fair-sized bits of stuff that will allow of being planed flat. Indeed, I have of late laid hands upon all such staves and cask heads, which I plane up and keep in the shape of small square boards ready for any such odd jobs. But I must return to the shelves. The double tenon is the best if the shelf is over 6in. in width. It is represented in Fig. 2, and of course a single tenon is wedged in the same way; but if there are three or four shelves, only the top and bottom ones need be so made, the others being slid into grooves or made with quite short tenons that will not come through the sides. The removal of two or four wedges from these shelves on each side will thus free the whole, and reduce them to flat boards, ready for packing. A great deal of oak furniture might be thus made, and very convenient it would prove. If wedging is objected to, a very good plan is to pin the tenons through edgeways with either hard wood or metal pins, each tenon having its own, as *ab* of Fig. 4; or with one long metal pin right through, if the width is not too great. The front of the hole can be countersunk, and a turned knob made to hide the pin, like B, which is partly in section to show the cup-like form; the head of the pin projecting into the hollow, so that when the knob is removed it can be got at and pulled out. Unless for the sake of portability, glued tenons will hold if well fitted, and need not project or be visible; but if shelves are to hold much weight, one here and there ought, at any rate, to be more strongly secured. Given a supply of nice clean oak stuff, and skill to use a saw and plane, there is nothing to hinder an amateur from fitting up to a great extent his own study. Even the Glastonbury chairs are very simple; and are wedged up on the same principle as the shelves; and an oak table with crossed trestle legs always looks well. When curved stuff is needed, a sweep saw must be used, but there is no difficulty in using it unless it be that the blade must be kept always truly perpendicular to the flat face of the board. A finely-set spokeshave, or plane with curved sole, or one of the American ones with a sole made of thin steel, which can be made to take any desired curve at pleasure, will be all that is needed to follow the saw, with perhaps a rasp and file to finish.

Fig. 1.

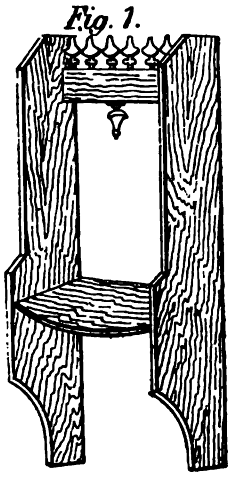


Fig. 2.

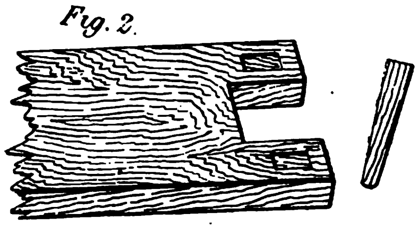

Fig. 3.

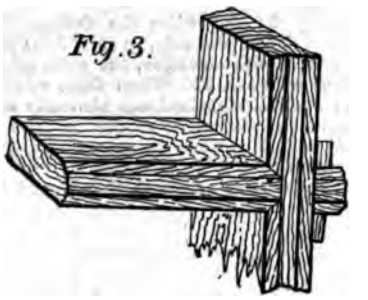

Fig. 4.

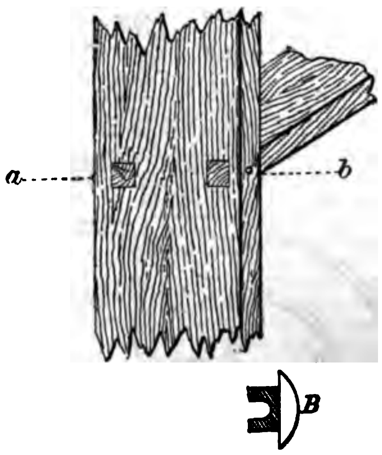

What I mean by trestle legs is shown in Fig. 5. They are cut out with a turn saw of oak board 1in. thick. A hole bored in the centre of each takes the tenon B of a long bar, round or flat; but the tenon is to be rounded and slotted for the wooden wedge that secures the parts. There are various patterns used; but the plain double curve shown is as good as any. The tenons above are mortised into a pair of flat rails, which take the table top. The latter is attached by screws put in from below, and which do not appear on the surface. If the tenons are pinned, this table may be taken apart in a few minutes; but it is very stiff and strong. There are many quaint designs of oak furniture which can be carried out in equally simple manner, besides those usually called ecclesiastical — strong substantial articles which would repay an amateur's trouble a great deal better than the usual ones that are given birth to in the home workshop. As regards the appearance of all work of this class, due care

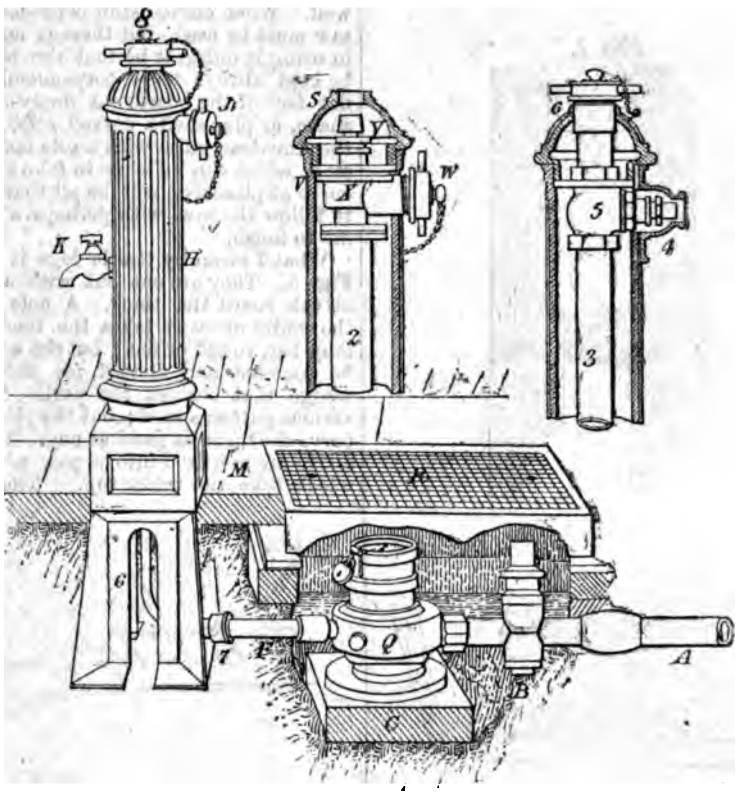
PRACTICAL NOTES ON PLUMBING.— LXXXIII.*

By P. J. Davies, H.M.A.S.P., &c.

Water-Cart Hydrants.

THIS hydrant is shown fixed at H J K, Fig. 393. Here the pipes from off the meter are usually of iron, and at times a meter is fixed as shown at Q. There are various kinds of meters, but the one generally in use is that working upon the principle of reaction (as in Barker's mill), a section of which is shown at Fig. 394. This is a drawing of a meter made by Guest and Chrimes, and one which, some 18 years ago, I fixed at Brixton, Peckham Rye, and Queen's-road railway stations (and many other places). It has worked well ever since, and I shall have occasion to speak of this meter hereafter. In Fig. 393, at Q, may be seen one of J. Tyler and Sons' meters. They are excellent water measurers, and good enough for all practical purposes, and are becoming well known. In front of the meter, as at B, is fixed a stopcock; and in a tube between the stopcock and meter is fixed a strainer, for which see the section of Guest and Chrimes's meter at 2 B and 6, Fig. 394. At A, Fig. 393, is the joint connecting the lead pipe to the stopcock. I have here shown a plug stopcock, because I fixed this class of stopcock at the before-named railway stations, and which for this purpose stands well, though now the screw-down kind is generally enforced. When fixing these meters as shown carefully protect them from the frost. Cover the dial with a plug of hair felt, in shape something like an ordinary pen wiper; and at F, or where most practicable, fix an emptying cock to empty the pipes. H I J, Fig. 393, is the before-mentioned hydrant, and which we will now call a street standpost; the water is supplied by meter or otherwise. When the water is on constant, the shut-off valve, to supply the water to the standpipe, may be fixed as shown at the section 5 and 4, Fig. 393, which in this case allows the standpipe to be screwed on the firehose cap 6; but when the firehose is required to come off the side, as at W J, as shown in the section and elevation, the valve is generally fixed as at X Y. When these valves are fixed as shown, the standpost generally stands charged for the purpose of supplying pails, &c., as at the cock K; hence one reason why we call it a standpost.



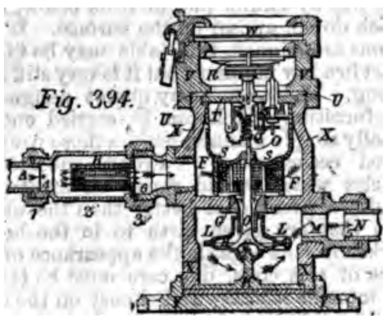


Fig. 394.

When such cocks are fixed, they should be of the class known as waste-preventing cocks, a section of which is shown at Fig. 394 A.

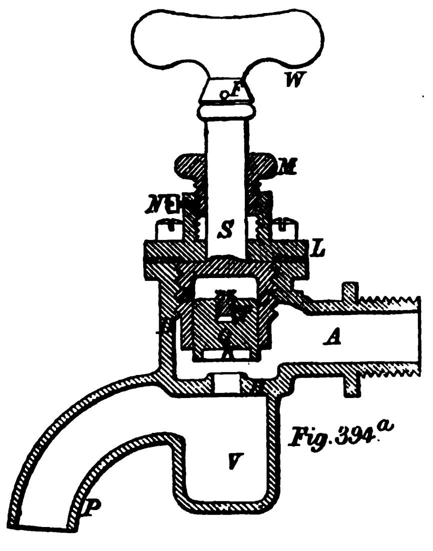

Fig. 394^a

This is known as Tyler's waste, not cock, the action of which will be readily understood from the following: It is worked upon the same principle as the valve described at Figs. 151 A, 161, and also at Fig. 185.

A, Fig. 394, is the outlet, B the valve seating, K the rubber valve, Q the falling plug which is actuated by the close-fitting socket or

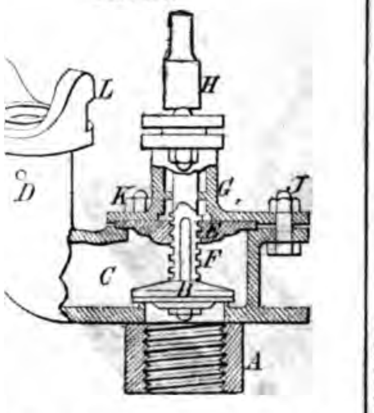
g the aperture over the seating T is d the water allowed to run during the his diaphragm remains off the seating, not be long, because there is a small ; *h*, which allows the water to pass 1 below to above the bottom diaphragm versa; that is to say, when the top . is depressed, and the lower diaphragm water will be forced back through the rture *h*. Sometimes the falling plug worked in conjunction with the dia- modification of which is shown at Q (Figs. 396, 149, &c.). Sometimes valve is formed on the diaphragm, and ade to actuate the diaphragm, whilst mes the diaphragm is made to actuate plug, &c. At Fig. 397 is a section of

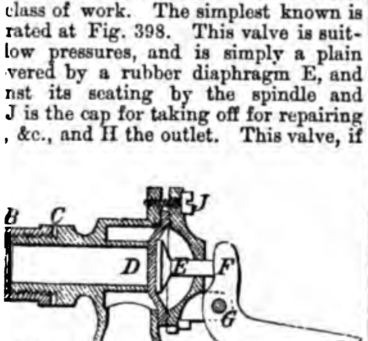
FIG. 397.



drant, showing the valve to be of the e kind (as in the Rotherham cock, the being the plate E), and round the stuffing-box with glands. Q holds the standpipe, and fastens it to the valve- er the method of the bayonet-point, of the best and quickest methods of upling.

Ball Valves.

he fittings connected with plambing, one of so much importance as the of an efficient and good ball valve. ld receive the most careful attention of er, for a ball valve suitable for one ill be for another utterly useless. I fore, show and describe a few suitable class of work. The simplest known is rated at Fig. 398. This valve is suit- low pressures, and is simply a plain vered by a rubber diaphragm E, and nst its seating by the spindle and J is the cap for taking off for repairing , &c., and H the outlet. This valve, if



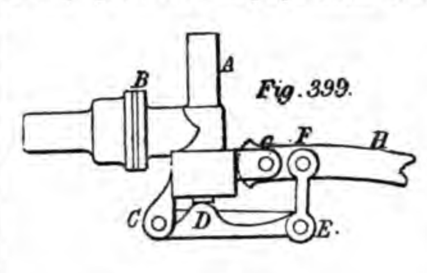
398.

g is reduced to a small bore, say ⅛in., is ly good for feed cisterns to boilers. e has been made to an endless number it patterns, and to various shapes, many have been patented, but are not so good ginal pattern, Fig. 398.

fixing the ball valves, see that there are avings or dirt under the seating before it, as such will cause the valves to let ter. By closely examining this valve 400) the principles of the safety valve een, and it will act as such when fixed wn.

ound Lever Pattern Ball Valve.

99 is an elevation of one of these ball d Fig. 400 a section. It will be seen simply a disc and L a valve, which is its seating by the short lever D, and which, by the pin E and connecting link U, is connected to the long lever at F; G is the pin or fulcrum of the long lever H; M is the spindle for keeping the valve L perpendicular to the



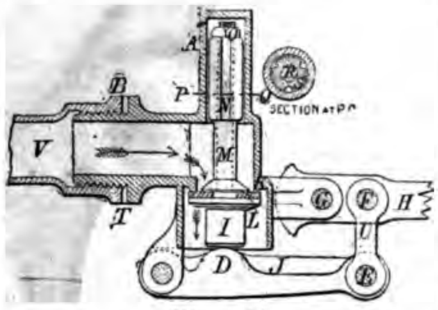


Fig. 400.

base of the seating; and N the feathered guides working middling tight within the cylinder A P. R S is a plan of the same.

The action is as follows:—The water enters at V, passes on and through the seating; but when the valve is closed as shown, the water is upheld according to the power put upon the ball and levers H D.

CAUTION.—When fixing or examining this valve, do not pull up the ball with much force, or you will strain the bottom lever or cut the valve rubber, and so render the valve useless.

This valve is a nuisance when the water is constantly on, as it is of all valves the longest shutting off, the long lever having further to travel in proportion to the closing of the valve than the lever of any other ball valve.

(*To be ontinued.*)

ENGERT'S IMPROVED STEAM BOILER.

AN improved steam boiler, designed by Mr. A. C. Engert, and constructed by Fraser and Fraser, of Bromley-by-Bow, has been at work in the factory of the designer at Three Mills-lane for over 10 months, with advantages which we shall proceed to describe. The boiler in question consists of a cylindrical shell, 7ft. in diameter by 16ft. 6in. long; but instead of having two circular flues, as is usual with Lancashire boilers of those dimensions, it has only one furnace flue and a return of the following dimensions. The upper, the front portion of which contains the furnace, is 4ft. 8in. wide and 10in. high; the "flat" construction demanding stays which are supplied in the shape of a number of 3½in. water tubes placed 9in. apart. The under or return tube is similarly constructed, but is only 4ft. 6in. wide; and there are two flat ends secured to the shell in the usual manner. The front portion of the upper tube is spread out into a sort of flattened bell-shape to form a furnace which is strengthened by rings about 12in. apart. The fire bars slope towards the front, and are turned up 3½in. to prevent the fire from sliding off into the box in which is placed the door. The fire itself is shielded by one of Engert's curtains or shutters, which prevents draughts of cold air from rushing over the top of the coal. This curtain is [illegible] to the damper that when th[illegible]

is closed. There [illegible]

the grate, and n[illegible]

down the bott[illegible]

fall through th[illegible]

ever, the inve[illegible]

jet impingi[illegible]

to assist [illegible]

tion of [illegible]

arrang[illegible]

known, and that although the boiler is fed by water from the Lea it never scales, and is perfectly cleansed by simply washing and brushing out. This latter result is partly due to an arrangement for heating the feed. In what may be still called the flue chamber a tank 4ft. 8in. wide, shaped so as to occupy the full length at the upper part of the boiler, but curved where the top flue enters and the gases sweep round and down to enter the lower flue, is placed, open to the atmosphere, and supplied with water by a cistern. This water is heated by the flue gases, and also by steam passing through a pipe, whence it flows towards the furnace and supplies the small jet above mentiond. By this arrangement the impurities of the feed are thrown down to the bottom of the tank, whence they are removed by a blow-off tap daily. Mr. Engert's object, however, is not only the removal of the lime, &c., but also the gases contained in the water, as he holds that the violence of explosions is considerably increased when a mixture of steam and gases has collected in a boiler. Without subscribing to that opinion, most steam users will agree that the plan of depositing "scale" outside the boiler is decidedly an improvement. The passage of the furnace gases through the flattened flues, impinging as they do against the vertical water tubes, creates a rapid circulation of the water, and the result is seen in the test trials which have been made, which give 11·3lb. of water evaporated from 82° Fahr. per pound of coal, the area of the grate being only 13 square feet. That is equivalent to 13lb. from and at 212° Fahr. The firing was done at intervals of about 25 minutes; nearly half a hundredweight of coal being thrown into the furnace at each feed without producing more than a slight colour in the gases escaping from the top of the chimney. Such results as these are obviously worth the attention of steam users, who, we believe, can see the boiler at work any Tuesday or Wednesday, at Mr. Engert's Works, Three Mills-lane, near Bromley Station, Tilbury and Southend line.

THE DYNAMO: HOW MADE AND HOW USED.—VII.*

By SELIMO R. BOTTONE.

Currents given by these Machines not continuous.

§ 15. SINCE the direction of the current changes at every semirevolution of the armature in such machines as those of Clarke, Pixii, and Siemens, and at every passage of the compound armature before the poles of the inducing magnets in Soren Hjorth's machine, we are constrained to use a commutator whenever we desire to produce a current in one direction only. But the commutator, by the very fact of its being necessarily constructed of two or more portions of a metallic cylinder, separated by intervals of insulating material, interrupts the passage of the electricity every time that the springs press against the insulating spaces. Hence the electricity furnished by these machines partakes more of the nature of rapidly succeeding waves, than of a steady continuous current, like that furnished by the battery. Still, when the armature is rotated at a high speed (and the Siemens requires to be driven at about 3,000 revolutions per minute, to give the best effects), these waves succeed each other with such rapidity as to simulate a steady current, no break in continuity being perceptible to ordinary tests.

Rapid Magnetisation and Demagnetisation produces Heat.

§ 16. It is found that the sudden change from north magnetism to south magnetism, which takes place in each half of the above described armatures, as they pass over from before a south pole to before a north pole of the inducing magnets, is accompanied by a very considerable rise in temperature; and that this rise increases with the rapidity of change of magnetism, which in its turn depends on the rapidity of rotation. So [illegible]ed is this rise of temperature, that a dynamo with a Siemens armature of the pattern [illegible] 14, and started at an initial tem- [illegible] rises in about twenty minutes [illegible] driven at 3,000 revolu- [illegible]ise in temperature is [illegible] of the machine.—

1st. Because the wires of the armature, becoming heated, conduct less freely; hence loss of current. 2nd. Because the armature itself is not capable of such intense magnetisation when hot as when cold (a red-hot mass of iron is hardly affected by the magnet); hence another loss of current. 3rd. Because the insulating covering of the wire is impaired, even if not actually ruined, if the temperature exceeds a very moderate limit.

For these reasons it is important to keep the temperature of the armature as low as possible. The first successful step in this direction was taken by Dr. Pacinotti, of Florence, in 1860, who constructed an armature of soft iron, in the shape of a ring, around which were coiled, in successive sections, helices of insulated copper wire, the ends of which were joined up to a divided ring commutator. The ring armature of soft iron, with its covering of wire, was supported on a central axle, and rotated before the poles of a magnet, either permanent or electro. At no part of the revolution is such a ring taken as a whole farther from, or nearer to, the poles of the magnet; and although its magnetism is constantly changing, yet the change is not abrupt, but gradual and continuous; as will be explained in the following paragraph.

Pacinotti's Ring Armature.

§ 17. The description and illustration of this machine is to be found in the *Nuovo Cimento* for the year 1864, under the heading of "Una Descrizione d'una Piccola Macchina Elettro-Magnetica." The machine itself, as described, can be used either as a motor, or as a generator of electricity; and its adaptability to either purpose was specially dwelt upon by Dr. A. Pacinotti, in his communication; but it is only under the aspect of a generator that we shall stop to consider it here.

Two electro-magnets S, N, Fig. 13 (which may, or may not, be united together below), are fastened to a base-board, and so arranged that the upper extremity of one is a north pole, while the other is a south pole. These poles are furnished with semicircular prolongations B B, B′ B′, between which is poised, on the axis C D, a soft iron ring A A. This ring is attached to the axis by means of radial arms. Coils of insulated wire are wrapped round the ring at short intervals about its periphery, the end of each coil being brought down the axis at D and attached to one of the small copper strips at E (of which there are as many as there are coils around the ring), the wire beginning the next coil being also metallically connected to this same strip. The wire terminating the next coil is fastened to the next strip, from whence starts a fresh coil, and so on, until all the strips, which form the compound commutator E are connected to the coils in such a manner that the end of one coil, by its attachment to its strip, forms the commencement of the next. Consequently, the wire forming the coils, although capable of communicating electrically with the springs F F at opposite points of the diameter of the commutator, is really continuous. The ring A A is caused to rotate by means of the rigger G and the driving belt H.

It will be evident on reflection that the half of ring opposite the pole marked N will acquire by induction *south magnetism*, while the half facing the pole S will for a similar reason become *north*. Hence the ring, whether in motion or at rest, will, provided the electro-magnets be active, become a circular magnet, with the S. pole facing the N. pole of the electro-magnet, and its N. pole facing the S. pole of the electro. When the ring is rotated, though if viewed as a whole, this magnetic condition remains unaltered, yet, of course, any given portion of the ring will gradually change as it passes over from one "horn" or prolongation of the magnets to the other. Still, the change which takes place is not abrupt, but gradual, and partakes more of the nature of a *wave* than of *shock*. So also, since the springs of the commutator press on several strips at the same time, at no time is contact ever entirely broken between the commutator and the springs; therefore the current which is produced as a continuous wave, *always in one direction*, is collected in a similar continuous manner by the springs F F, and may be employed where required by coupling up the wires I I.

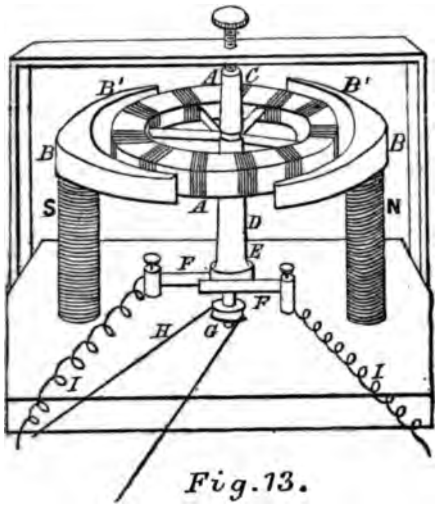

Fig. 13.

This machine, discovered more than 20 years ago, embodies all the essential characteristics of the best modern machines, and the much-vaunted machines of Gramme, Brush, Siemens-Alteneck, Maxim, Edison, &c., &c., are, at best, but trifling modifications of the Pacinotti ring machine—modifications which have not always been improvements. Having now brought our brief sketch of the essentials of a dynamo to a close, we shall proceed in our next section to constructive details.

Ten years ago iron rails were manufactured by all rail makers, and steel rails by comparatively few; the latter now form 95 per cent. of the total output.

positions of inclination, in this feature meriting the favourable opinion of Wale's original model expressed by Dr. Carpenter.

COMETS.

UNDER this title, Mr. E. B. Knobel, Secretary of the Royal Astronomical Society, delivered an address at the Royal Victoria Coffee Hall, Waterloo-road, S.E., on Tuesday week. It formed the fourth of the series of Penny Science Lectures now being delivered in that building under the auspices of the Gilchrist Trustees, and, like the earlier ones—which have been reported in the last three issues of this journal—was illustrated by a series of views shown by the oxy-hydrogen light. The theatre was well filled, the address was attentively followed, and at the close the lecturer was called before the curtain. Having alluded to the fascinating nature of the appearance of comets, and to the interest they have awakened in the minds of all observers from the earliest periods, Mr. Knobel described some of the larger and more interesting comets that have been noted, showing illustrations of each upon the screen. The comet of 1264 was one of great brilliancy and excited great attention; it was now lost to our system. In 1680 a comet appeared which was rema
not only for its great splendour, but becau
its movements Edmund Halley, or
labourer, calculated its orbit and predic
of its return. The science of mathema
comparatively in its infancy, the w
tions had to be performed without t
can obtain, and were in themselv
intricate that the minds of most m
from undertaking so gigantic a

persevered, however, and ultimately ascertained the orbits of some 24 comets; this of 1680 he believed to have a period of 575 years. Two years afterwards, in August, 1682, another comet appeared, which Halley found agreed so exactly in position with one which Kepler had observed in 1607 that he believed it must be the same; and he was confirmed in this opinion by the fact that a similar comet had appeared in 1531. He calculated its orbit, and predicted that it would return at a period between 75 and 76 years. Its return would be, he considered, somewhat delayed by its proximity to the great planets Jupiter and Saturn, but he believed it would be completed in the winter of 1758, and left on record an instruction to astronomers to keep a look out for it in that year, and should it re-appear to recollect that it was an Englishman who foretold its period of return. As the time for the reappearance approached, two French astronomers, Clairaut and Lalande, resolved to test the prediction, and to ascertain the exact period at which the comet, now known as Halley's, might be expected. The arithmetical calculations were undertaken by Lalande, who was assisted by a French lady, Madame Lepaute, and they continued at the laborious work for six months, sometimes

r and
for,

was ascertained with such exactitude, although it could be followed by human eyes during an exceedingly small portion of its journey, that its reappearance in August, 1835, was predicted within our days of time and one degree of space of its actual place and period. It will not reappear until the year 1911. In 1836 another comet was seen, of which illustrations were shown; the coma was a nebulous mass like a Medusa's head, and the whole was very indistinct. In 1743 a comet was seen and named after Cheseaux, which had six tails of nearly equal length and brightness. Mr. Knobel added that he had a few days since examined the original drawings and notes made at the time of its appearance, and could, therefore, testify to the correctness of the extraordinary-looking illustration; while quite recently some entirely independent observations made in a Russian observatory at the time had been published, and confirmed those previously made known. The lecturer also showed illustrations of the great comets of 1811 and 1843; the former had a very long tail, and the latter was remarkable from being visible by daylight, and from having approached nearer to the sun than any other known comet; as the wine crop of that year was exceptionally good, it received, as most persons could remember, the name of the "comet wine." Incidentally the lecturer mentioned at this point that the tails of comets were continually changing in appearance, and seemed to be no more an appendage to the loose nucleus than was the smoke of a steamer a portion of the vessel. The analogy was very complete, for the tail was continually streaming away into space, and that seen one night was by no means the same as that seen another. Very many comets showed a dark space in the centre of the tail, beginning a little below the head. Most of the elder members of his audience would remember the magnificent appearance presented by Donati's comet, the next of which he had illustrations, during the autumn of 1858. Not only was the tail extremely long and brilliant, and of a feather-like form, but there were curious faint rays noticed on the upper side, and Professor Bond, of Harvard University Observatory, noticed also a singular pulsation in the tail, which was afterwards recognised by others. This pulsating movement of the light had been seen in earlier times, and was easily detected in the comet of 1876. This very beautiful comet of Donati would never again be seen by any of his audience, for its period of revolution was reckoned at about 2,000 years. Recurring to Halley's comet, he might mention that it had been calculated that this was the one recorded to have been seen soon after the death of William the Conqueror, and that it also appeared about twelve years before the birth of Christ, and although it had not been seen since 1835, we knew its exact position in its ellipse at the present time, and almost precisely the date at which it would reappear. No doubt his audience would like to know how we were able to calculate the movements of a star only seen for so extremely minute a proportion of its circuit. The calculations were too complex to explain in so short a lecture, but it depended on observations of the velocity at which a comet moved towards or from the sun, during the time that it was about the same distance from that luminary as the earth; if this rate of velocity was less than 26 miles a second while at this part of its orbit it must be brought back by the sun's attraction at some future period, the time being shorter in proportion to the slowness of the movement, and we, or our descendants, would again see it. If the velocity exceeded 26 miles a second, the comet would go off into infinite space, and was certainly not a member of our system. Later in the evening, the lecturer exhibited photographs of the telescopic comet seen that day year, from negatives taken at the Cape of Good Hope by Mr. David Gill, the Government astronomer, and mentioned that these photographs often revealed details as to a celestial object more clearly than could be observed by the astronomer, while they afforded a faithful record for future reference. This comet had but a slow motion, and a period of revolution round the sun of about 600 years. On the night of 30th July, 1861, everyone was attracted by the sight of a great comet, which then attained its greatest brilliance, in the north-western sky, illustrations of which the lecturer showed. This comet came so near to the earth that astronomers believed we must on that day have passed completely through its tail. Many independent observers reported that the atmosphere and sky on that night had a peculiarly luminous appearance, and some considered that it exhibited a phosphorescent appearance. Another noteworthy comet was that known as Biela's, which was observed in February, 1826, by an Austrian officer of that name stationed in Bohemia. The path was seen to be
ntical with comets which had been seen several
before, notably in 1772 and 1806, and it was
termined that this comet made a revolution
in about six years and eight months.
redicted, in 1832; but was in an
tion in 1838, and so escaped ob-
ppearance in December, 1845,
, not one, but two,

distinct comets occupied its place, moving in distinct and independent orbits in close proximity, and sometimes one and then the other was the brighter till they finally disappeared in the following April, 1846. In 1852, these two parts were further separated, and since that time it has never been seen, although on one occasion, in 1872, we passed near its right path. Where had it gone? Most of his hearers would remember that in August, and again about the end of November, the earth crosses the path occupied by great numbers of meteorites or "shooting stars," and that on these nights, especially about the 27th to 30th November, showers of these shooting stars were visible. They were found to have stated periods of special brilliancy, and always to radiate from definite points in the heavens, and these facts set men thinking as to their cause and character, and as to whether they had any connection with comets. In 1872, when we ought, as he had just stated, to have seen Biela's comet, or comets, in September, it had disappeared, but on November 27th we passed through a dense shower of these meteoric stars, and these occupied the exact position where the comet should have been observed at that period. These were not apparent in Europe, but, suspecting that such a shower would be seen, a German astronomer telegraphed to Mr. Pogson, at the Madras Observatory, to look on the track of the lost comet, and see if any fragments, as it were, in the form of meteors, were visible, and, as he had just stated, they were found as expected. There could be no doubt that these represented the lost comet of Biela. Meteors, it was evident from frequent observations, were very small bodies travelling round the sun in dense swarms, in orbits which brought them at certain times comparatively close to our earth. They could only be seen when they came very near indeed to us, and their brightness was the result of their having to encounter the resistance of the earth's atmosphere, and so being rendered white hot, and ultimately burnt up. They then fell upon the earth, as dust or stones, and a fine collection of these meteoric stones could be seen at the British Museum. By means of the spectroscope, it was now easy to analyse the component parts of any light, the lines and bright spaces in the ray on the spectrum divided by the prism being an absolute test. Dr. Huggins succeeded in examining the faint light of a comet by this means, and found that the spectrum was marked by the same dark lines and bright spaces as the light from the blue portion of a gas flame or common candle, and on breaking up and burning meteoric stones similar results were arrived at. The theatre of the Royal Institute was illuminated one evening in 1881 by gas produced from such stones, when it was evident that the light from comets, from meteors, and from coal-gas were almost identical. The lecturer showed copies of spectra observed from a recent comet and from gas in illustration of this point. From all these accumulated facts it was believed that comets were made up of aggregations of meteors, for (1) not only did they move in the same paths, but (2) dense masses of meteors were found in 1872 in a space previously occupied by a comet, and (3) the composition of the light of comets exactly agreed with that of meteors, and with those which had fallen as stones to the earth. But only a few comets belonged to our system; some of the most splendid apparitions that had illuminated the heavens moved in infinite space unfettered and untrammelled.

THE TRANSMISSION OF ENERGY.
II.*

By Prof. Osborne Reynolds, M.A., F.R.S.

In my last lecture I dealt with the transmission of energy through the means of coal and corn, showing that by either of these means power may be transmitted by rail, with an expenditure of 1-12,000th per mile, or by water of 1-120,000th per mile, this either through the agency of horse or steam. This ease of transmission, however, depends entirely on the railroad or water, and is only possible between places so connected. Hence such means are only applicable to what may be called the mains of power.

We come to-day to consider other means of transmitting energy in smaller quantities applicable to its distribution for immediate application. Such transmission is not a matter of secondary importance, although the distances over which it is transmitted may be comparatively insignificant.

Now the means of artificially transmitting power may be considered as three. The power may be stored in matter in various ways, and the matter with the energy transported—as, for instance, in our watch springs. The second means is the transmission of power by moving matter, without actually storing the power in the matter—as in shafts and belts, hydraulic connection, &c. And the third method, which is distinct from the others, is the transmission of energy, in the form of heat or electricity, by the flow of currents through conductors; in this way all the power in the steam passes through the boiler-plates from the furnace into the boiler. Of course, each one of these means includes an infinite variety of detailed contrivances, more or less dissimilar. But there is good reason for classing them under these three heads, for all the contrivances under each of these heads are subject to the same general limits, whether those of efficiency or distance.

There is one thing in common to all these means of transmission, and that is that they all involve a material medium. The quantity of matter required constitutes a primary consideration in all of them. This quantity of matter is fixed by what we may call the properties of matter, one of the most important of which, as regards the first two means, is the possible strength of material. Looking round, we see the effect of the limited strength of material in all nature's works. Of course it may be that we shall be able to work with stronger materials than we have at present. Organic materials, such as the feathers and tissues of animals, are stronger than steel, weight for weight, so that there is a possibility of improvement; but that man will go beyond nature in constructing organic fibre seems improbable, and such possibility of improvement as exists may be discounted. At present we may set down our strongest working material as steel, the art of working in which is so perfect that we may calculate on nearly the greatest strength for all purposes. I have taken fifteen tons on the square inch as the limit of safe working tension, in making the estimates which I shall now bring before you. First of all, I will ask your attention to the possibilities of transporting power in a stored form.

The question of economy in the conveyance of energy in a stored form is simply one of the intensity with which it can be stored. If we want to carry energy about, we must have it stored in some material form—and this material has to be carried by ordinary means—so that the question of economy is simply the amount of available energy that we can store in a given amount of material.

If energy, stored in a particular manner, is more readily available for some special purpose than that stored in another, then it may, on the whole, be more economical to carry it in that form. This is abundantly illustrated in our watch springs.

The greatest amount of energy that can be stored in a given weight of steel is very small, compared with other means. To take a familiar unit, to store the energy necessary to maintain one-horse power for one hour would require no less than fifty tons of steel—that is to say, fifty tons of steel in the form of watch springs, all fresh wound up, would not supply one horse-power for one hour; and yet this is the commonest form in which energy is carried about.

It is the adaptability of the spring, and the readiness with which energy can be put in and taken out, which recommend the steel spring.

Indiarubber will store much more energy than the same weight of any other material, say, eight or ten times as much steel; but with this several tons would be required to store the horse-power for one hour. A much more capacious reservoir, according to its weight, is compressed air. There are certain difficulties in getting the energy in and out without loss; but with air, compressed to four times the pressure of the atmosphere, we should only require about 20lb. of air to yield the amount of one horse-power for one hour. Of course, if we were going to carry this air about, to the weight of the air would have to be added the weight of a case to contain it, and such a case, in the form of steel tubes, would weigh something like 230lb.; so that, in any form in which we can carry compressed air about, we shall have about 300lb. to carry for each horse-power per hour.

Another means of storing energy, very largely used, is hot water. This is largely used in a way not always recognised. The boiler serves another purpose besides that of converting the energy of the furnace into the power of the steam. It stores the power, and equalises the stream between the fire and the engine, a function the importance of which has been brought to the front in the recent efforts to apply electricity for communication of power, where the want of a similar reservoir between the generator and the motor has, in many cases, proved fatal to the enterprise, a want which secondary batteries are now being used to meet. Hot water has also been employed as an independent reservoir, and as such it is better in some respects than compressed air. The fundamental limits are of much the same kind. In this case, however, the absolute limit is temperature. The vessel in which the water is carried must be strong enough to withstand the pressure, and all materials lose their strength as they get hot. The considerations are here much the same as in the steam engine, and 100° Fahr. appears to be about the limit. At this temperature, for every 4lb. of water the cases would weigh 1lb., and there would be no advantage of large over small cases; except as a matter of construction, the proportionate weight would be the same. The gross power of a pound of water, the steam being used without condensation, is about 20,000 foot-pounds, or we should require 50lb. to store 1,000,000; this is the extreme limit again. The present accomplishment would be about 150lb. per 1,000,000 foot-pounds stored—rather less than compressed air. The only other means of packing power that is at present looked to is that of the much talked about secondary battery. Here there is a great deal of doubt as to what is actually accomplished; take the most reliable statements, from which it seems that in order to get 1,000,000 something like 100lb. of battery is required, which will make this means of storing energy very much the same as compressed air or hot water.

It is important to notice that the initial cost of the energy stored by these means differs considerably. The cost is rather difficult to estimate; but a practical estimate may be formed in this way:—

Taking the power, as delivered by the steam-engine, as 1, how much of this power will be given out after secondary storage? Here the hot water has an advantage, for it is heated directly by the coal, and is all on its way to the steam-engine.

With compressed air there are three operations, each as costly as the steam engine, and at least half the initial power is spent during the compression, storage, and expansion; so that the energy is at least double as costly in coal, and six times as costly in machinery. I have put it down as three times as costly as the energy in hot water, but this is considerably below the mark. The electricity has also to go through three operations, and cannot be less costly than compressed air.

Now, if we revert for one moment to the consideration of the main transmission of power, we see at what an immense disadvantage any form of packed energy is compared with coal or corn; as at present packed it weighs at least 100 times as much.

While the limits imposed by the strength of material render it certain, as far as compressed air and hot water are concerned, that the weight can never be reduced by more than half, these limits are sufficient to show that packed energy cannot be transported over long distances, even if it can be obtained direct from such falls as Niagara. But this is no argument against the importance of these means for short distances and special purposes. As I have already pointed out, our watches show that circumstances may render the very heaviest means the best for particular purposes. And if in any of its forms packed energy were directly available for household purposes, though it cost ten or twenty times as much as power direct from the steam-engine its use would still be assured.

One fact should be noticed, that in all these forms the power is packed, and needs nothing but drawing off, whereas corn or coal do not contain the power. The oxygen is an equally essential ingredient. In this fact lies the great advantage of corn and coal for transportation. They are really, so to speak, but cheques for power, which can be cashed at any spot where a bank, in the form of a steam-engine or a horse, exists. But, of course, not being energy, they are not generally current—in fact they are worthless, except where the bank exists, and where they represent such small amounts that the banks refuse them. Now these forms of packed power are, so to speak, generally current, that is to say, they are available under almost all circumstances, and in greater or less degree of smallness; from the very smallest, which is the watch spring in our pockets, which supplies a continuous stream of power in less than one ten thousand millionth of a horse-power; or the Whitehead torpedo, which carries some million foot-pounds of energy under the sea. Perhaps the most pressing purposes for which these forms of packed energy are wanting is that of locomotion.

The distance which a locomotive body, be is animal or machine, can travel, loaded or free, is limited by the ratio of the power which it carries to its gross weight. The speed which it can attain is limited by the rate at which it can use its energy compared with its weight. Hence there are two particulars in which we can compare the different forms of stored energy for locomotive purposes.

Let us take the horse and the locomotive. A full-sized horse weighs, say, 1,500lb., and, at a rate of 2¼ miles an hour, will go five hours without food, doing about 10,000,000 foot-pounds of work, including the work necessary to move itself; this represents the largest result, or about 150lb. per 1,000,000 foot-pounds. If the horse is put to ten miles an hour, it will not do more than 1·5 million foot-pounds in a single journey, besides moving itself. Probably the greatest rate at which a horse can use its energy is about 4,000,000 foot-pounds per hour, or 750lb. per horse-power.

A locomotive with its tender, say, weighing sixty tons, exerts 500 horse-power gross — 270lb. per horse-power per hour — so that a first-class locomotive with tender is above one-fifth as heavy for its power as the horse; but then the horse cannot go more than ten miles an hour.

Now, in a general way, passenger locomotives carry coal and water for eighty or one hundred miles,

---

* Abstracted from the Cantor Lectures, delivered before the Society of Arts.

i.e., two hours; or the locomotive already mentioned expends at one run about 2,000,000,000 foot-pounds; which means that the gross weight of the locomotive is about 60lb. or 70lb. per 1,000,000 foot-pounds of power with which the locomotive starts.

In thus taking the gross weight of the horse or locomotive, we must remember that this includes the weight of carriages and machinery, and that in whatever form the energy is carried this weight must be added. In the locomotive the weight of water and coal in the tender for two hours' journey weighs about one-quarter the gross load; and if we add the weight of the boiler we may consider the carriage and machinery at one-half to one-third the gross load. Taking the latter, and substituting for the boiler, coal, and water, energy in either of the above forms, the coal, water, and boiler would be about 40lb. per 1,000,000: so that, if we took compressed air instead, we should have one-fourth the power; or the engine would run for thirty minutes instead of two hours, a distance of twenty-five miles instead of a hundred. A fireless locomotive might do more than this, say, thirty-five minutes, or thirty miles, at the same speed as the locomotive. Faure's battery, if it could be made to work at all, would carry the locomotive fourty-eight minutes, or thirty-five to forty miles.

These figures seem to show that the locomotive has little to fear from any of these rivals, that is, under circumstances where the smoke and steam are no harm, and where a full-sized locomotive is required. But there are already some cases where the locomotive is required and where the burning of coal is impossible. Should the Channel tunnel be made there will be a great field for some form of packed energy; but it does not seem that the promoters have much faith in a smokeless means of working the tunnel being forthcoming.

Coming back for a moment to Faure's battery, I would carefully point out that the result which I have put down—100lb. per 1,000,000 foot-pounds of energy—refers to what has been already accomplished, and not to any possible limit.

It should be noticed, however, that although the means of doing so are still entirely wanting, could other metals, such as iron or zinc, be used instead of lead, the result would be much greater. This is shown by the relative amount of power necessary to oxidise or deoxidise these materials, which we see for iron and zinc are five or six times greater than for lead; here is an apparent opportunity for art.

But if sciences as yet imposes no limits beyond those I have mentioned, at the same time it holds out no prospect. The chemistry of these batteries has been very deeply considered, and those who have studied the subject most deeply apparently see no direction in which to direct their efforts; so that any great advance in this art must entail a great discovery in science.

USEFUL AND SCIENTIFIC NOTES.

Pouchkoff's Modification of the Holtz Machine.—As well known, the fixed plate of the Holtz machine, as at present constructed, carries *externally* two paper armatures that are charged in order to prime the apparatus. Each of these armatures is fixed at the edge of an aperture through which one or several paper points act upon the movable disc. In order to simplify the construction of the machine, and avoid the always delicate operation of making apertures in the plate, Mr. Pouchkoff, after gluing the armatures on the exterior of the latter, glues the points on the interior and connects the two by a horseshoe-shaped band of paper on the edge of the disc. The machine thus constructed works, according to Mr. Pouchkoff, just as well as one of the ordinary kind.

Sauer's Voltaic Cell.—Her Sauer has constructed a battery that acts only in sunlight. It consists of a glass vessel containing a solution of 15 parts of table salt and 7 parts of sulphate of copper in 106 parts of water. Within is a porous cell containg mercury. One electrode is made of platinum, and is put in the mercury; the other is of sulphide of silver and is placed in the salt solution. Both are connected with a galvanometer, and the whole is inclosed in a box when not in use. When the battery is placed in the sunlight, the galvanometer needle is deflected to a certain point and the sulphide of silver is found to be the negative pole. Any change in the intensity of the light, such as a cloud over the sun, is indicated by the needle. The action of the battery depends on the effect of the chloride of copper upon the mercury. Subchloride is formed, and reduces the sulphide of silver; but this can only take place with the aid of sunlight.

THE proportion of doctors to the population in different countries is given as follows by the *Siglio Medico*:—France, 2·91 per 10,000; Germany, 3·21 per 10,000; Austria, 3·41 per 10,000; England, 6 per 10,000; Hungary, 6·10 per 10,000; Italy, 6·10 per 10,000; Switzerland, 7·06 per 10,000; United States, 16·24 per 10,000.

SCIENTIFIC NEWS.

SUCH observations as have been made of comet Pons show that it fluctuates in brightness in a remarkable manner, and indicate that useful work may be done by taking careful note of its brightness on every opportunity. M. Bigourdan is evidently inclined to the belief that comet Pons at least has a light of its own. The following ephemeris continues that given last week, and will probably enable the observer to detect the comet in spite of the moonlight:—

	R. A.	N. Dec.
	h. m. s.	° ′
Nov. 7	17 17 49	51 27·6
9	17 22 37	51 5·9
11	17 27 40	50 44·1
13	17 32 59	50 22·0
15	17 38 35	49 59·6
17	17 44 29	49 36·8
19	17 50 42	49 13·4
21	17 57 16	48 49·1

Apropos of the result of the Geodetic conference, it may be mentioned that "Bradshaw's" map is in future to have lines ruled at every $1\frac{1}{4}$° of longitude, showing time-intervals of five minutes. In the United States a scheme is on foot for adopting the time-standards proposed some months ago. At present there are no fewer than forty-nine time-standards used on the different railway systems, but it is proposed to divide the whole railway system of North America into five sections, each having uniform time, viz., that due to the 60th, 75th, 90th, 105th, and 120th degrees of longitude west of Greenwich—*i.e.*, if the Greenwich datum is adopted. The 60th meridian will practically be confined to the British Maritime Provinces, but the 90th meridian will be "central time," and will include by far the larger part of the railway system of the country. For many of the cities in the central part of the States local time will be only a few minutes fast or slow of the railway time, and in the ordinary course it is inevitable that the town clocks will be regulated to those of the railway stations.

The monthly meeting of the members of the Royal Institution, on Nov. 5, will be occupied mainly in the election of a manager in the room of the late Mr. W. Spottiswoode, president of the Royal Society.

The annual meeting of the Mathematical Society, on Nov. 8, will be occupied chiefly in the election of the new council, when it is probable that the names of Messrs. W. D. Niven, F.R.S., and J. Hammond, M.A., will be substituted for those of Prof. C. W. Merrifield, F.R.S., and Dr. J. Hopkinson, F.R.S., who are obliged to resign.

At the meeting of the Essex Field Club last Saturday, two papers on Deneholes were read by Messrs. F. C. J. Spurrell and T. V. Holmes.

It is proposed that the memorial to the late Prof. Jevons should take the form of a studentship, of not less than £100 annual value, the holder of which shall devote himself to economic or statistical research. To commemorate the connection of Prof. Jevons with the three cities, the election would be vested in representatives of University College, London; Owens College, Manchester; and University College, Liverpool. A very strong and widely representative committee has been formed.

The telephone patent case in the United States is becoming more complicated. Edison, Voelker, and Irwin have appealed from the decision of the examiner of interferences as regards the claims of Bell; and Edison, Bell, and Gray have appealed against the decision which awarded the telephone receiver to McDonough.

Meantime, the McDonough Telephone Company has been incorporated with a capital of one million dollars, with liberty to increase it to twenty millions.

The Thomson-Houston Electric Company, of Boston, were awarded the first prize for the best arc-lighting system at the Cincinnati Exhibition.

The American Ornithologists' Union was duly organised at the meeting called by Dr. Elliot Coues and Messrs. Allen and Brewster. It will be limited to fifty active members, with power to elect a hundred foreign or corresponding members. One of the principal objects of the Union is to establish a uniform nomenclature for North American birds, and the committee appointed for that purpose consists of Dr. Coues, and Messrs. Allen, Ridgway, Brewster, and Henshaw. Amongst the subjects which will engage the attention of the union is the position of the European sparrow in North America. It appears that he has made himself very much of a nuisance.

According to Prof. Collett the mastodon is a much more recent animal in North America than has been generally supposed. Thirty specimens have been found in Indiana, mostly in marshes or other miry places, some in such good preservation that the bog-cutters used the "fat" to grease their boots.

At the recent meeting of the Society of Anthropology and Geography, held in Stockholm, Baron Nordenskjöld gave an account of that part of his expedition to Greenland which was intended to discover remains of any Norse settlers on its south-eastern coast. He managed to force his way through the ice to a harbour in about 66° N. lat., where fresh traces of Esquimaux were observed and plants found which are common in Greenland only in the neighbourhood of European settlements. The expedition failed to discover any signs of the "populous districts," but is valuable as demonstrating the possibility of reaching a coast which has been rarely visited.

To make their returns complete, the Board of Trade will have to ask for a record of instances of continuous brakes averting accidents. The other day a disaster was avoided in the North by the prompt action of the Westinghouse brake on a train which broke up through being thrown off the metals; and recently an express train approaching Chicago in the early morning was saved from wreck by the power placed at the disposal of the driver by the same pattern brake. The driver noticed smoke ahead, and suspecting danger, applied the brake, which enabled him to pull up within 30ft. of a burnt bridge and prevent the train from plunging into the abyss.

M. Body, of Lecornette, in the Ardennes, has invented a new and ingenious fire-damp detector. It is essentially a safety-lamp of the Davy type connected with an electric bell. Contact is prevented by a catch held back by a cotton wick impregnated with some chemical preparation. When the fire-damp reaches dangerous proportions the wick ignites, the catch is released, and the bell rings. It has been tried with advantage in the mines of Cockerill and Co., at Seraing.

Ericsson's Sun Motor.—Captain Ericsson is engaged upon a motor worked by the solar heat. The rays of the sun are caught and carried to a reservoir, where their heat converts water into steam, which is used for running a small engine. This invention is designed to be used in pumping water on the plains, where its small cost would make it very valuable.

A PATENT has been taken out in Germany for a new process of enamelling ceramic articles. The glass, terra-cotta, stoneware, porcelain, or similar article, is covered with a film capable of conducting electricity, by painting the article with a solution of chloride of platinum or nitrate of silver and burning this in, and then decorating as desired, with enamel. This is burned in, and the article is afterwards covered electrolytically with the metal. The galvanic coating does not adhere to the enamel, and very varied effects can be produced by gilding, silvering, colouring, polishing, platinising, &c., the metallic surfaces of the articles.

M. J. L. SORET brought under the notice of the Académie des Sciences at the séance of the 10th of September, in a note, his interesting researches on "L'Absorption des Rayons Ultra-Violets par les Substances Albuminoides." The *Comptes Rendus*, No. 11, informs us that all the albuminoid substances studied gave a common principle, to which the absorption band is due. Gelatin, though much more transparent, shows no band.

DR. LAUJORROIS in *Cosmos les Mondes* recommends potassium dichromate as an exceedingly useful deodoriser and disinfecting agent. He considers it would be of great use in the treatment of diseases due to microbia.

DR. KOLLER in *Centralblatt für Textil Industrie* draws attention to the fact that if silk tissues are impregnated with chromate of copper, and then exposed to direct sunshine, various shades of brown may be obtained, and the silks are rendered waterproof. This peculiarity of the chrome salts, especially of the chromates of copper and mercury, was published in the Report of the Cork meeting of the British Association in 1843.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the Editor *of the* English Mechanic, 31, *Tavistock-street, Covent-garden, W.C.*

All Cheques and Post-office Orders to be made payable to J. Passmore Edwards.

⁂ *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original." —*Montaigne's Essays.*

SOLAR PROMINENCES—COMET PONS.

[21983.]—In reply to Mr. Franks (letter 21954), I fear it is simply impossible to ascertain the cause of failure of any arrangement for viewing the "solar prominences" without a personal inspection. In this instance there ought to be dispersive power enough to show the "chromospheric lines"; but he considers eight prisms (direct-vision) the smallest number capable of exhibiting the "cloud" and eruptive prominences, in the manner pointed out in his letter.

Comet Pons.—I was fortunate in obtaining a capital view of this newly discovered body on Saturday morning, 27th October, at about 8.30 p.m. A large nebulous haze surrounded a comparatively small nucleus; but the traces of a tail, if any, were exceedingly faint. The R.A. and N. Dec. were taken from MM. Schulhof and Bossert's corrected ephemeris in your last issue.

James Pearson, M.A., F.R.A.S.

Fleetwood Vicarage, Oct. 29.

ERRATA — ε EQUULEI — PAIRS IN CAMELOPARDALIS—PONS'S COMET—δ EQUULEI.

[21984.]—I notice two misprints in letter 21924 page 147. For "rates it at 8·8 mag., Σ remarking," read "rates it at 8·8 mag. Σ, remarking"; and for "The most distinct companion," read "The most distant companion."

The reason that H missed the close pair of ε Equulei (letter 21928, p. 148) was probably owing to the fact that the stars were too near together to be elongated with the 6·3in. reflector in 1780 and 1781, while the close pair certainly was far too difficult in 1823 and 1827 for the small refractors used by Sir J. Herschel. The distance is probably still slowly increasing, Do's measure (0·83″) in 1877 being too small, as might be expected from the character of the telescope used. Two recent measures are: Hall, 285·0°, 1·05″, 1879·7; Perry, 285·0°, 1·23″, 1882·7. The wide pair *n.f.* Σ 2848 is Sh 336 (226·0°, 105·8″, 1823·7). The pair mentioned by Mr. Holmes (letter 21930) near Σ 385 Camelopardalis seems to be new—that is, if it is not Σ 397, as Mr. Franks suggests. Mr. Holmes (letter 21955, p. 471) says that his pair is "just 5′ directly following" Σ 385. Even supposing that he has written 5′ for 5m., a most objectionable practice, yet Σ 397 is 28′ north of Σ 385. There is no star 5′ exactly *f.* Σ 385. Hall gives 0·70″ in 1879·58 for the distance of Σ 400; Seabroke's measures are incorrect, for, unfortunately, the last Rugby results in Vol. XLVI. of the "Memoirs" are very poor. However, they are not so bad as the "measures" (save the mark!) of southern double stars just published in Vol. XLVII., as these are simply disgraceful, and certainly ought never to have appeared in the publications of the R.A.S.

M. Bigourdan has noticed at the Paris Observatory the remarkable variations of light in comet Pons alluded to by Mr. Lane (letter 21931, p. 148). Curiously enough, the French observer says that on Sept. 23rd it appeared in a small telescope as an 8th mag. star, and on the 24th the same, the diameter of the nebulosity being nearly 2′. On the 6th October, the nucleus was as faint as a 12th mag. star; but the comet was more easily perceived than at the beginning of September. Its light on the 23rd Sept. was 30 to 40 times greater than that indicated by theory.

I stated by mistake, in letter 27196, p. 37, that the period of δ Equulei was about 13 years; it is really 10¾ years.

H. S.

CAMELOPARDALIS, &c.

[21985.]—The compositor has put R.A. in letter 21955, where I think I wrote P.A. Mr. Franks will find that the star he mentions is not the one I inquired about as new. My star is in the field with Σ 385 with a high power. I have a wire across e.p., and when I rotated e.p., so that 385 travelled straight along the wire, the new star followed on the wire. The e.p. takes in just 6¼′ of arc, and both stars are in field at once. The R.A., D., P.A., and distance all differ from 397, as given by him. The pair are also smaller than Mr. Franks states, the *comes* being much more delicate than 10·5 I should think. I beg to thank him for taking so much trouble. The air here has been so thick since I noticed this star that estimates both of distance and magnitude are necessarily little better than guesses.

I can assure him that it was not being omitted in Webb that led me to think it new, but the fact of being so near Σ 385, and finding that others had looked at 385 and yet missed seeing this double.

Query 52070. May I query the querist? "Is he sure he perfectly divides δ Cygni with 4½in.?"

I must leave the query of "Vigilans," 52102, to "F.R.A.S.," pleading want of competency on my part to answer it, and a little surprise at finding myself bracketed with your eminent correspondent. I should like to ask if any objection exists to making flats of razor steel. This takes a high polish, which it retains for years undimmed, without any particular care to keep it so; I judge it to be brighter a good deal than speculum metal. Has it ever been used? I recollect it being mentioned to me 30 years ago by workmen, who at that time said they could polish it equal to the finest quicksilvered mirror. In fact, I have seen small hand mirrors made of it. The freedom from tarnish would be a great advantage.

Edwin Holmes.

COMET PONS - BROOKS — JUPITER WITHOUT HIS SATELLITES — RED SPOT OF JUPITER.

[21986.]—On October 20 I saw the comet for the second time, having seen it first on Oct. 4 or 5. I searched for it on several occasions between these dates, but the weather was too unfavourable to see it. Can the variation in its visibility, mentioned by J. Lane, have been caused by the almost imperceptible mist of which we have had so much lately? On clear nights, though not sufficient to render small stars invisible, it is quite enough to blot out so faint an object as a comet or nebulæ. Especially is this mist troublesome on nights like the present; perfectly clear, with the temperature hovering a few degrees above freezing all through the night till 3 or 4 a.m., when it sinks to freezing, and the mist vanishes, crystallised, I suppose, into frost, and planet and moon grow sharp and distinct in every detail.

On Oct. 15, I saw Jupiter without his satellites; but two were really visible all the time, hanging on, one to each limb.

At 15.10 on Oct. 20, after having observed the moon for some time, I turned to look at Jupiter. The indentation in the belt, which marked the position of the once famous red spot, was a little past the C.M.; but no vestige of the red spot could be seen. The thing of beauty has *not* been a joy for ever, in this case.

M. A.

SATURN — ERRATA — DOUBLE STAR NEAR Σ385 — THE BERTHON DYNAMOMETER.

[21987.]—In reply to the question of "F.R.A.S." (letter 21953, p. 170), of course the crape ring should be narrower where it crosses the ball than in the ansæ—the width of it on the planet appeared to me about equal to that of the outer ring at the same point. As regards its want of conformity where it crosses the limb, I had not noticed any peculiarity; but possibly the great difference of aperture would account for it; certainly I never had such views of Saturn with my 5in. achromatic as shown by the 11¼in. reflector; indeed, with the latter instrument I have even seen the cape ring in sunshine.

In my letter (21954, p. 171) I notice two typographical errors. The compositor has made me say "Camelopardalis," a redundant solecism, whereas I wrote "Camelopardus," following, as I always do in these matters, the terminology of my respected friend, the Rev. T. W. Webb. The other mistake consists in introducing an accented "é" into Struve, which I don't think an improvement, as that eminent astronomer always wrote his name as I put it.

I presume Mr. Holmes (letter 21955, p. 171) means 5m. (not 5′) following Σ 385, and that "R.A. 25°" applies to pos. angle 25°? If so, it agrees fairly well with Σ 397, as mentioned previously.

Mr. Perkins (letter 21951, p. 155) makes some startling revelations with respect to the Berthon dynamometer. It is really a very important matter to know that the gauge itself is correct before proceeding to measure eyepieces. My limited experience corroborates his own, and I should not trust any of these instruments unless personally verified by actual measurement with a stage micrometer on the microscope.

W. S. Franks.

ASTRONOMICAL — THE ELECTRIC LIGHT FOR OBSERVATORY PURPOSES—NEW FORM OF LECLANCHE BATTERY—OBSERVATION OF THE SOLAR PROMINENCES.

[21988.]—I am afraid your correspondents, "H. S." (21796), and Mr. Gaudibert (21876), will think me very dilatory in replying to their communications. But I can assure these gentlemen that I would gladly have answered their queries concerning β Delphini and δ Equulei before, had I had anything to communicate. I have on several occasions lately tried to see the respective companions of these very difficult stars, but hitherto without success. The air has been so unsteady, and the seeing so indifferent on every occasion that the weather has permitted the attempt, that I am sorrowfully obliged to say with the needy knife-grinder, "Story! God bless you. I have none to tell, sir." Several times I have had *fancies*, but fancies are not allowed to pass muster in matters astronomical; so that unless I could certainly see and measure the companion, I have confessed myself defeated. And, indeed, no wonder. The moments of good definition are so few and far between on this east coast, that the chances of being able to see and measure such exceedingly difficult stars as these during an apparition are small indeed. I believe all that a telescope can do my 18¼in. Calver will do, as far as its aperture extends; but no telescope in the world can deal with delicate and difficult stars when they are flaring, fluttering, and jumping as if possessed. And such is their normal condition in Northumberland when the sky is clear.

However, to show "H. S." that I have by no means abandoned double-star observation, but, on the contrary, take a very keen interest in this most delightful branch of astronomy, I send my measures of a few stars made during the year, as far as time and opportunities have permitted; and I hope, during the winter, to have a few good nights on which to make some more.

I can fully bear out what your different correspondents have from time to time said as to the great advantages of the electric light for obser
tory purposes. I first tried the bichromate
but I found the trouble of lifting the
out of the fluid so great, when you w
means to save time, that I cast
better form of battery. This Messrs
Swan, of Newcastle, have supplied

being sold for half a guinea an ounce, is scarcely worth sixpence."

Again, a dealer has sent me samples of what appears to be very fair "block tin," saying, As the regular chemical analysis is rather a long business, and I am very busy at present, would you mind examining it pyrologically for *lead* with your blowpipe, and send me the result?—You will find inclosed a considerable quantity of *brown oxide of lead*, derived from your block tin, in the following manner :—(1) Fragment on C. slip, Al plate ("E. M.," Figs. 11 and 46) H.P. The red-hot assay, which at once fuses to a ball, must be kept with a shining surface, by covering it carefully with a good blue H.P. (*a*) Whatever lead alloy may be present in the assay will be sublimed, and deposited as a white sublimate on the vertical surface of the plate, where it turns *brown* in P.P. (*lead*). (*b*) When all lead or antimony, &c., has been thus extracted, and no further *separate* sublimate can be obtained, an O.P. *on* the assay will at once cover it with a kind of efflorescence of snow-white pure tin oxide, on which P.P. has no further effect than turning it yellow while hot. This pyroxide (SnO_2) separates the large flakes, and can be thus rapidly collected and re-formed, until no metal is left. This oxide can, of course, be reduced to chemically pure tin.

"Last, not least," a faithful study of Pyrology will bestow upon the student a severe training in the mental analysis of *any* subject, whether chemical, political, or literary, which will enable him (with, *à priori*, a due knowledge of the particular subject at issue), to rise, if he have natural talents, to the very top of the nationalistic tree; for, as in evolutionary organisation, so in the analytical process of the human mind, nature has only one method of pushing forward from the bare protoplastic fact given to be detected, by parallel, analogical, and inductive supplements (supplied, of course, more copiously by the more original mind), and rise to perhaps brilliant and novel conclusions or *facts*, which might even alter or correct, and must certainly benefit the knowledge of the whole thinking world.

As an illustration of the application of how the mental part of this method of analysis to the solution of a purely literary problem, the authorship of the "Vestiges of Creation," it may be mentioned here, that overwhelming proofs can be, or rather have been, afforded (in plain English), that the late Dr. Robert Chambers could not possibly have been the author of that celebrated work; and, in a second part of the essay or assay, other proofs scarcely less convincing, that the author was no other than the late Sir Charles Lyell. Both these conclusions have, since the essay was written, been verified. 1. Mr. Churchill (publisher of the book) has distinctly stated that Chambers was *not* the author. 2. Sir C. Lyell, in a letter to Prof. Haeckel, as good as admits that he *was* the author. **W. A. Ross.**

MICROSCOPE MOUNTING.—SLIPS AND MICRO-COVERS.—I.

[21992.]—To begin quite at the beginning, microscopic objects are mounted—i.e., preserved so as to be always ready for examination—by fixing them on a slip of glass or wood, and protecting them by a covering glass. Of mounting on wood, I have no practical experience; but it would evidently be useful in two cases—at least for those who are in the way of cutting the wood of the proper size and shape. Firstly, it would do as well as glass for opaque objects, and, indeed, for all objects which are intended to be seen by reflected and not by transmitted light—that is, practically, by the bull's eye and not by the mirror. Secondly, minute objects may be mounted in air or Canada balsam between two covering glasses, and fixed with gold size or some other cement on a wooden slide, in the centre of which a hole has been cut to receive the light from the mirror or condenser. This arrangement gives the power of bringing the condenser quite close to the object. Hard and fine-grained wood should, I presume, be employed. However, glass slips have to be resorted to for the great majority of objects, and, for the sake of uniformity, are commonly made use of for all. They are three inches in length by one in breadth, and average a little more than a sixteenth in thickness; the thinnest should be kept for objects which it is intended to observe with high powers, as a condenser cannot be so conveniently used through thick glass. They are, according to Dr. Carpenter, made of "patent crown" glass; and they should be free from scratches, bubbles, or other marks—at least in the centre where the object is to go. Anyone who has the necessary facilities may of course cut "patent crown" into the above shape, and grind down the edges; if not, ground-edged slips can be bought for about 8d. a dozen, and unground-edged at about half that price. I would recommend the purchase of, say, a dozen unground slides to commence with, and the subsequent use of ground-edged to prevent scratching.

Covering glasses are cut with a diamond from very thin and brittle glass, by laying it on a sheet of wet plate glass. They are generally sold in ¼-ounces, at the rate of from 4s. to 8s. an ounce, and of three thicknesses:—No. 1, very delicate, and requiring to be most carefully handled, for high powers and test objects; No. 2, medium; and No. 3, thicker, and made of exceptionally large sizes, for live-boxes, &c. Squares and circles are the usual shapes, and the circles are a little dearer than the squares, but, I think, more convenient in any case, and certainly much more so if the mounter has a circle board, without which he will find it very difficult to mount neatly. The vendors will mix different shapes and sizes, and a ¼oz. will last a good while; the most useful sizes are ¾, ⅝, and ½in. The contents of a ¼oz. box will often be found of very different thicknesses, even if they have been bought as all of the same kind. After a while, they are easily distinguished by the feel; and a few of them may be measured with a micrometer to begin with. Those of ·003in. are thin enough for all purposes. For exceptionally large objects special slips must be procured or cut with a diamond, and, if thought necessary, ground at the edges. Again, the objects may be mounted lengthwise, and special covers, longer than they are broad, are made for mounting such objects; or, for inspection with very low powers, they may be mounted between two slips.

II. *Ringing.*—Mounting is either in (1) air, commonly called dry mounting; (2) resinous substances, as Canada balsam; (3) syrupy fluids, of which by far the best is glycerine; or (4) thin fluids, which usually contain corrosive sublimate. The resinous substances gradually dry and harden, and the slip only needs to be cleaned before mounting the object; but in the other kinds of mounting it is always advisable previously to make a well on the slip of the shape and size of the covering glass which it is intended to use, so as to prevent the object from being unduly pressed on, the fluid from running out, and the cement or varnish from running in. To make a "cell," as the little chamber thus formed and inclosing the object is termed, it is first necessary to clean the slips, as neither cements nor varnishes will adhere firmly to dirty glass. This may be done by washing them in warm soap and water, then in pure warm water, and, finally, if any dulness or specks should remain, rubbing them with a cloth moistened with methylated spirit. They may then be dried with a clean rag, and brightened up with that invaluable thing in microscopy, a clean, soft old silk handkerchief. The next step is accurately to find the centre of the slips, which may easily be done with a circle-board or turn-table, or without it in the following manner:—Lay a slip on a piece of white paper or cardboard, and draw four fine lines round the slip, using it as a ruler, and taking care to hold the pen or pencil upright, or so to use it that the lines on opposite sides of the slip shall be at the same distance from its edge. Do not draw the lines quite to the corners, but take away the slip, and continue them by a ruler till they meet, which will give opposite corners more exactly than if the slip itself were used. Then draw two lines exactly from upper right corner to lower left corner, and from upper left corner to lower left corner. The point where they meet will be the centre of the slide, and should be marked by a dot. If then any slip which is nominally 3in. by 1in.—for the slips naturally differ a little in size—be placed over the figure thus drawn, so that its opposite sides are over or at equal distances from the lines left by placing the original slip on the cardboard and drawing round its edges, the dot will be under the centre of the slip. Make then another ink dot just over it, on the slip itself, holding the eye perpendicularly over the slip, so as to mark it straight. These marked slides will be especially useful in mounting in resinous substances or air, the object being mounted on the other side of the slips and the dot made on the bad side, if there is one. Parallel circles or squares may also be drawn an the cardboard round the dot, an eighth or so of an inch apart. Being seen through the glass, they will help the eye in drawing a square or a circle on a slip.

The next step is to draw a ring or circle with a brush dipped in cement. Cements, by the way, are different from varnishes, which are neatly or showily coloured liquids, 'intended for finishing off slides, as slips with mountings on them are called, from their being slid on the stage of the microscope. Cements have greater tenacity; and the most trustworthy are marine glue, gold size, and Bell's cement, among which gold size is preferable in practice, as it can be used without heat. The first thing to see to is that the cement (which must be of thoroughly good quality) is neither too thin nor too thick. If too thin, it will tend to run on the slip, and must be laid on in correspondingly thin layers; it will thicken in time, or by leaving the cork sideways in the bottle. If too thick, it will not run or will leave threads behind it; and ought to be thinned, gold size with turpentine or benzine, and Bell's cement with spirit. Only a few drops of the thinning liquid should be added at once, and the bottle shaken, for it is easy to add more, but impossible to remove what has been added. The liquids appropriate for thinning varnishes should be inquired when the varnishes are bought; they are usually turpentine and benzole, and are generally marked on the bottles. For cements, a small camel's hair pencil may be used; but for varnishes more delicate lines can be traced with a small sable pencil. All pencils should be cleaned after use in the liquid appropriate for thinning the varnish or cement, and special care should be taken of sables. They may be kept from becoming harsh by being moistened with tallow, being cleaned with turpentine before use. In drawing a cell, the brush should be well moistened with gold size, or whatever else is used, but not so as to drip; and if it threatens to do so, it may be held upside-down for a moment or so. The pencil should touch the slide at an angle of 45°, or rather less, and at a tangent to the circle to be formed—I say circle, because a circular cell is more easily made than a square. If a turn-table is used, the faster it is made to rotate the better, within reasonable limits, the slip being fixed so as not to fly off. In this way cells of $\frac{1}{16}$in., or thicker, may be made with ease; but only thin layers should be laid on at once, and a new layer should not be added till that beneath it is of a quite waxy dryness. For thicker cells, a single layer of gold size may in the first instance be laid on the glass as just described. Then a button-ring—a brass or vulcanite ring, or a slice of glass tube—should, when the layer is waxy, be coated by a brush with gold size on one side, laid by that side on the layer, and firmly pressed down with as much pressure as can be used without breaking the slide. It should then be left to fix by the drying of the size. In this way cells of any depth may be constructed; but it is better not to use (as sometimes recommended) paper, or wood, or readily-corrosible metals. If the objects are to be mounted in air, nothing more need be done, except, perhaps, to clean away any superfluous cement by a rag or a piece of cotton wool stuck on a stick like a minute mop, and moistened with spirit. If they are to be mounted in glycerine or thin fluids, the interior of the brass or vulcanite should be carefully and entirely covered over with gold size, so as to prevent possible corrosion. No spaces by which dust can get in, or, in wet mounting, fluid escape and air penetrate, must, of course, be left between the ring and the glass. The cement of the rings should be perfectly dry and hard, so as to be almost chippy, before a covering glass is put over them and an object mounted; otherwise they are apt to run in, or to lose their shape. Their tops must be of the same height all round, without irregularities, which would break the covering glass, or leave spaces between it and the top of the cell. Any slight irregularities left after the ring is first made will disappear on laying it quite flat. The size of the rings ought to be calculated by that of the covering glasses to be employed, which should reach quite to, or a little beyond, the middle of the ring, but not to or beyond its outer margin. When an object is to be mounted—say, when the apparatus is being got out—a very thin layer of gold size should be applied to the ring, to soften it, and enable the covering glass to be pressed down into it so as to fix it, and to prevent the minute interspaces which are the demons of wet mounting.

No cell, remember, should ever be deeper than it is necessary to make it. The object should touch the slip on the one hand and the cover on the other, so as to fix it in the centre of the cell, except in air mounting, or where brittle objects are in hand. And, again, the larger the circumference of the cell, the greater is the danger that some defect may occur.

III.—*Finishing, Varnishing, Labelling, and Cataloguing.*—Omitting for the present the description of the process of mounting itself, about which many mistakes would be made as to selecting objects, staining them, &c., if I were to attempt to describe it here, I will conclude with a few remarks on the above subjects, taking up in my next communication the preliminary examination of objects. Mounted slides may be cleaned from superfluous Canada balsam, or whatever may have been used, by rubbing the slip with a cloth moistened in turpentine or benzole. The covering glass may be cleaned in the same way, but *very* carefully; and they may be finished by cleaning with methylated spirit. If Canada balsam or any other resinous substance has been used, the rough of it should first be taken off by a small-bladed penknife. The slides may then be varnished, but it is distinctly better not to varnish them; and if it is desired to do so, for the sake of neatness, two months, or even more, should be allowed to elapse before it is undertaken. The process of varnishing is precisely the same as that of ringing. To save lengthy description, I would recommend the reader to inspect at a shop some of the best-looking slides prepared by professional mounters. Zinc white, and black, red, green, and gold Quekett's varnish are the best and most commonly employed; they are laid in a ring over and round the edge of the covering glass, so as to look neat and cover defects.

For Canada balsam and other resinous mounts, the best varnish is a ring of Canada balsam and chloroform thus laid on. After another couple of months or so it may be covered by any other varnish. Again, white may be laid down as a ground, and black lines put over it, or green lines (circles) may be drawn over the yellow of the gold size; and so *ad infinitum.* The varnishes may also be used to indicate at a glance the character of the slides; thus green may be used for plants and red for animals; but as to things of this kind everyone will devise plans for himself, and perhaps take the trouble of carrying them out. I will afterwards give receipts as to labelling. Ornamental paper covers for slides are sold; they are best left alone, as if either the mounting goes wrong or the first labelling should have been inaccurate—and both of these things are possible—they have to be painfully taken off. The best thing is two paper labels, one near the top, carrying a description of the object, and another near the bottom, with a number or other detail. These labels are best made of stiff paper, not white, as they become dirty, but tinted. The greenish blue Society of Arts paper does admirably; it may be gummed, and the labels punched out or cut to shape with a pair of scissors. The gum should have a little glycerine in it to prevent it from becoming too dry, and three grains or so of corrosive sublimate, with a few drops of oil of cloves or some other essential oil to hinder it from growing mouldy while in the bottle. It should not be two thick, and two coats may be laid on. Labels such as drapers use may also be bought. I do not like a square label, as they are apt to rise at the corners, but a small circle for the bottom, and an ellipse or oval at the top, with an inscription in three lines, the upper curved upwards, the middle straight, and the lower curved downwards, so as to follow the shape of the label. The labels should be written on before being fixed on the slide, which may be done by carefully moistening the gummed surface only, and pressing them down with dry blotting-paper. As little as possible should be written on the labels, reserving a fuller description for the catalogue, as it is easier to write in a book than on a morsel of paper. The catalogue may be a fourpenny or sixpenny notebook, written on one side of the page, with three or four lines between each item left blank for additions. It should give (1) the number, (2) the nature of the object, (3) the method of preparation and the nature of the mounting employed, and (4) what is shown—failures, defects, and mistakes being plainly set down.

I give in illustration a couple of labels and the corresponding entry in my catalogue. *Upper label:* striped muscle (from leg of) blue bottle. *Lower label:* 93 G. *Catalogue:* "93 G, striped muscular fibres, M.F. $\frac{27}{19}$, from femor of bluebottle, showing an apodème. From undue pressure, most of the fibres have broken off, and some have partly split longitudinally, over lines of nuclei, from same cause. An unbruised batch, M.F. $\frac{31}{14}$. OsO_4 [Osmic acid] and glyc. [glycerine]. Tracheæ dark." M.F. refers to the numbers on "Maltwood's Finder."

F. G.

EQUATORIAL MOTION FOR TELESCOPE STAND.

[21993.]—I HAVE received so much pleasure from adopting Lord Lindsay's method of giving an equatorial motion to a telescope on an altazimuth stand, and have accomplished it so cheaply and so effectually, that I fancy many users of the telescope will feel interested in reading an account of it.

The telescope is a silver-on-glass Newtonian reflector, of 15in. diameter and 100in. focus, in a square wooden tube 9ft. long, carried on an iron ring 4ft. diameter, hung on an iron fork by two strong screws or trunnions, one through each end of the fork, and turning on them; the spindle of the fork turning in a strong iron tripod, and carried on a point on which it turns.

The tube with mirror and flat and eyepieces is counterpoised by two half-hundredweights hanging on the bottom and in the hollow of the fork, so that it will stand in any position in which it is placed, and it can be pointed to ten degrees from the zenith. A few pounds' weight are then added to the mirror end of the telescope, and the tendency of the front to rise is regulated by a string running through pulleys, between the telescope and an arm fixed on the spindle on which it turns, and thence to a gimlet in the side of the telescope near the eyepiece; and by pulling or loosing the string—it running over the shank of the gimlet—the telescope is pointed as high or low as required, and fixed by a turn of the string round the shank of the gimlet, and then in a nick in the handle. A pull of 1½lb. will move the telescope in azimuth.

A meridian line is marked from the spindle on which the telescope turns, and on this line a loop is fixed, just as far south of the spindle as for a line from it, the loop, to the centre of motion, on which the telescope rises and falls, and turns to point to the Pole.

To this loop a line is attached, and when connected to the front of the telescope and the telescope hanging on it at any and all elevations, an equatorial motion is given to the telescope, and a star followed by one motion of the telescope to the west. In fact, the loop and the axis of the telescope form a Polar axis, and when the front of the telescope is attached to the string and the string kept tight, it is an equatorial, and has the advantage over the usual equatorial stand, that the eyepiece is always horizontal when the telescope is pointed east or west. When on the usual equatorial stand, the eyepiece is turned down when the telescope is turned due east, and up when west.

The loop being properly placed, and the string from it running through a screw eye fixed in the middle of the bottom front of the telescope, a star or planet to be viewed is placed in the telescope in the usual manner.

The meridian string is then pulled tight through the screw eye, and thence to a second gimlet in the side of the telescope passed round the shank and made fast in a nick in the handle. The other string and pulley that have kept the telescope at the proper height may then be loosened, and the whole pull of the telescope be maintained by the meridian string. If, on looking into the eyepiece, the telescope is too high or too low, a turn of the gimlet will set it right, and the star will be followed by moving the telescope to the west as the star moves.

So far good if the star is on or near to the meridian; but if much to the east or west, the telescope will have a tendency to fall into the meridian owing to the pull of the meridian line.

To counterpoise this tendency of the telescope, I have a lever fixed to the spindle of the stand on which the telescope turns, and from it a string running through a pulley is attached to another lever, one end of which is hinged to the side of the room so as to rise or fall parallel to it, and a weight is put on this lever, and the string so adjusted that the lever is upright when the telescope is on the meridian, and falls as the telescope moves to the east, so that the pull of the string exactly counterpoises the telescope in every position east of the meridian. The motion of the telescope with the star is caused by the pull of another string on a second lever fixed to the same spindle of the stand, and regulated by the descent of a weight carried on the top of an air bellows, filled with air, and the outlet connected to a flexible tube, having a cock at the end which is placed near the eyepiece of the telescope, and the descent of the weight and motion of the telescope increased or lessened as desired, by opening the cock more or less. When the telescope is west of the meridian, the pull is in the contrary direction, and the string is passed through another pulley so as for the lever to fall and the weight to increase as the telescope is farther from the meridian, and it is equally counterpoised in every position.

The levers that turn the spindle, and which I state are fixed to it, are, in fact, fast-and-loose levers, fixed in a minute in any position, or removed altogether. They may be likened to large nutcrackers or lemon-squeezers, fixed to the spindle by a screw through the handles, and having a groove cut in them near the joint to nearly fit the spindle; they hold it perfectly tight, or, when unscrewed, lie loose, and the spindle is easily turned in any direction.

I make these levers very cheaply thus. A 3ft. length of 2in. square deal has a second piece of the same size, 2ft. long, hinged to it by a long screw passing through an oblong hole in the shorter piece, and screwed into the longer about 1in. from their ends. The screw is long enough to allow of the levers being ½in. apart—when the spindle is in a groove cut 5in. from the ends—and a shutterscrew (may be bought at any ironmonger's for 6d.) passes through the shorter lever at its other end, and screws into the nut fixed on to the longer lever—and a turn or two of the screw fixes the lever fast on the spindle. If inclined to slip, a little chalk will be an effectual remedy. These trifling and cheap additions to my telescope have added immensely to my enjoyment of it—as by the clock-motion a star may be kept any time in the centre of the field of view by an extremely small motion of the cock. To easily regulate this, I put the end of the tube (which I purposely fix to the cock) into a little water held in a tin vessel hanging on the telescope, and the noise of the bubbles of air as they escape from the tube into the water enables me to regulate the cock to the greatest nicety.

I am aware that in the usual stands for the Newtonian telescope the balance of the tube is to the eye end, and they are supported on a rod that is raised or lowered by a screw; but the same motion may be given to any one fixed in an observatory by a sliding rod fixed to a hook in the floor, and to the front of the telescope by a second hook, and sliding longer or shorter, like the legs of a camera stand, and I feel sure no one would be without the bladder clock who had once experienced the luxury of it.

Another addition to my telescope may be worth mentioning. Shutters are hinged to the inside of the tube of the telescope—each one having a hole in its centre to act as a stop—and a string fixed to the lower corner and passed through a hole in the lower side of the telescope, and thence round the bottom of the telescope, and through another hole in the opposite side, and then fastened to the same corner of the shutter. It is readily pulled across the telescope or back into its place, so that a stop is put on or taken off the mirror in the readiest way. I have two such in my telescope—one with a 9in. hole, and the other with a 7in. hole in it; and I find them very convenient, as they can be pulled across while the eye is at the eyepiece, or back again as desired. I ought to state that the star should be south of due east or due west; but if north of that, the meridian line should be fixed to the mirror end of the telescope, and at the top of that end. The balance weight should also be placed at the eye end, and all other arrangements reversed. This, however, I have never tried.

The position of the loop on the meridan line may be readily found by observing that if the telescope rises faster than the star, when observing a rising star, the loop is too far from the spindle; or if the star rises faster than the telescope, the loop is too near to the spindle. A few trials will soon indicate the true position; also that bricks are cheap and useful weights.

Philip Vallance.

THE PARKER-SMITH AUTOMATIC SCREW BRAKE.—TO MR. STRETTON.

[21994.]—WITH reference to your letter, page 154, I would explain that no personality was intended when alluding to your objections to mechanical brakes. You have doubtless had many opportunities of witnessing the trials of chain and friction brakes, and observed their unsuitability to general adoption, and therefore have every right to the opinion you have formed.

I must, however, object (with, I am sure, the large majority of our readers) to the statement that "*mechanical brakes* have had their day." In fact, several to whom I have referred this opinion have remarked, that they did not think it had *commenced* yet. Certainly many inventors are hard at work on this question, which would hardly be likely if it was thought that the ultimate perfection in mechanical brakes had been realised.

If any inaccuracy has occurred in my letter, page 132, pointing out the several little deficiencies requiring improvement in the air and vacuum systems, I shall only be too happy to be corrected. I acknowledge my failure when attempting to describe the Heberlein brake; but this was partially due to the printer omitting a couple of lines and perverting the punctuation. A very excusable error. Mr. S. seems to attach very considerable importance to the Board of Trade recommendations, and no doubt very rightly. They, however, are not entirely coincided with by some engineers. The Westinghouse brake is probably the only one that follows them in their entirety; but, as I have remarked before, there are several conditions and improvements—or rather, I should say, the absence of several defects required before the present forms of air and vacuum brakes will fully satisfy our engineers. There is no portion of the Board of Trade conditions which cannot be fully realised and fulfilled with the P.-S. system; and there are several very necessary qualifications not included in the Board of Trade conditions that this brake also possesses. Not the least amongst these is its adaptability for shunting purposes when disconnected from the engine—a difficulty Mr. Stretton suggests. As the sliding of a 15lb. weight on an inclined lever entirely controls the braking force on each carriage, a man could stand on the footboard and linking any portion of the chain on the hook provided, could control the brake as easily as the engine-driver or guard. This is one of the great advantages of mechanical brakes over air systems, which are of course useless when detached from the engine. It is absolutely essential that any train fitted with the air system is also supplied with the hand-screw brake in the guard's van to assist in shunting, and fall back upon when the air brakes fail. Of course the liability of the servants to forget to couple the brake chain would not be confined to the Parker-Smith system: they can forget to couple the brake connections in any system ever invented. Should, however, any individual carriage be linked up as described, and not coupled up, such carriage alone would be affected. On the other hand, were the fireman to omit to open a tap between the tender and first carriage, the whole train would be practically unbraked.

As regards the danger of the chain pulleys freezing up in winter time, this difficulty would mostly apply to a brake like the chain brake on the L. & N.-W. Railway, which being an emergency brake, may run for hours with the chain slack in the pulleys without being used. In the P.-S. brake the chain always being in tension, with a slight movement corresponding to the motion of the train, and the fact of it always being the stopping power, would reduce this contingency to a minimum.

Though the Westinghouse brake has the advantage of having all moving parts covered, it is found necessary to carefully drain them to prevent their freezing up; so I think mechanical brakes may be entitled to a litte attention.

In cases of the train breaking loose, I believe it is intended that all brake couplings should part without injury, or at least so little as to be easily repaired. With the P.-S. system the limit of damage would ensue. As an iron rod is substituted for the chain under the coach, whose longitudinal motion equivalent to the rising and falling of the weight is controlled by two collars, it follows that the weakest point will be the S, or attaching link, between the coaches. On the train separating, these S links would partially straighten, allowing the chain to disconnect, the weights would immediately fall, applying the brakes with full force, no damage resulting to the apparatus.

I think it may safely be granted that "the simplest means of securing a result being the best," is a fixed mechanical law, and that neither continuous brakes or railways should be any exception to it. I do not think that a trustworthy complication need be necessarily sacrificed to simplicity, *providing you secure the efficiency*. A continuous brake is certainly intended to be a life-saving apparatus, though it has occasionally proved the reverse. Simplicity is a very necessary feature in a continuous brake, especially regarding the rough work of railway service, yet it is not everything. Mr. Stretton mentions the old lever brake on coal waggons as an example of a simple brake. This, however, does not apply, as it could not be regarded as a continuous brake, neither does it fulfil the necessary conditions. I have no doubt Mr. Stretton will admit that the *theory* of every train or coach developing its own retarding energy is correct and sound in principle. The difficulty has been to arrive at this result practically, as the failures of the various trials mentioned by Mr. S. fully testify; but this, of course, does not alter the principle. A train should be stopped with the same ease and certainty that it is started; this is all the more necessary when we consider the high and increasing speed now obtained. It is not a comfortable reflection to travel at 60 miles per hour with the knowledge that the brake may or may not act. With mechanical brakes, as the momentum of the train at whatever speed, supplies in proportion the equivalent energy to check the train, it follows that the power is *always* available when required. I would also point out that a "screw" (the combined elements of mechanical principles) differs very greatly from a simple arrangement of friction wheels which wind a chain round a drum—the method of most so-called mechanical brakes.

The Parker-Smith brake may be described as a continuous hand-screw brake. Instead of the guard, the axle turns the screw, and by means of the connections this operation is simultaneously repeated on every vehicle provided with brake apparatus. All the engine-driver or guard has to do, is to let out as much chain equivalent to the braking pressure he wishes to obtain. The effect of this is to lower the weights on each carriage an exactly similar distance (as each is provided with the same length of chain), and regulate the pressure between the friction cones, causing the screw to revolve with more or less force; and carrying the part nut (working the brake levers) in either direction from the centre of the screw according to the direction the train is travelling. On pulling up the weight the part nut is disengaged from the screw and the brakes at once released. The screw brake can be applied at frequent intervals or kept on *ad infinitum* without fear of exhausting reservoirs or overworking donkey pumps. The screw brake is again free from the annoyance, drivers using the air-brake often experience and express, at large stations, when a number of vehicles uncharged are added to the train. The brakes on the latter at once fly on, the starting signal is lowered, and the driver finds himself unable to move till the pressure throughout the train is equalised. In large stations with heavy traffic this defect is apt to cause inconvenient delay. Under all these circumstances I think it is rather premature to insist that mechanical brakes have had their day and must now give way to better inventions, as we most certainly require more definite evidence that they exist. I should be pleased to observe the opinions of our mechanical readers on this subject. **Imprimatur.**

A "PATENT" FILE.

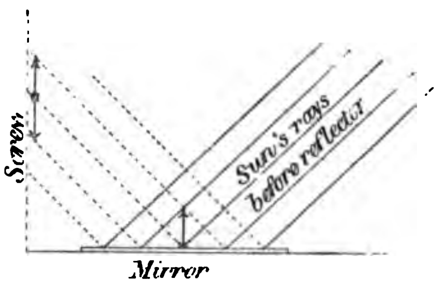
[21995.]—While I was in a shop this morning an idea occurred to me which I expressed to the assistant—viz., Why should not a file be made in the shape of a grindstone? I had been spending 20 minutes the same morning in filing off the ends of six screws which came through a piece of wood, and, in addition to trying my temper, it made my fingers ache. If I had had a *circular* file, I could have done it in a minute or two, and been smiling all the time, by placing the ends of the screws against a circular file fixed to a grindstone and giving the handle a few turns. I asked the man in the shop why such a thing was never made; but as he answered not, I suppose he did not know. Perhaps some of your readers can tell me? If such a thing *can* be done, and somebody will kindly make one (*without* patenting it), and let me know, I should be indebted, provided they don't put an exorbitant price on it. **L. B. B**

SHADOW v. MIRAGE.

[21996.]—If Mr. S. Ratcliffe will stand a small object (as a screw) upright on a horizontal looking-glass, in sunshine, and hold a sheet of paper vertically at a few different distances from the object, yet so as to receive the reflected rays, his difficulty will at once vanish.

Our good F.R.A.S. will forgive me for pointing out that he has only considered the rays of the sun falling on the water *between* the object and the screen—an easy oversight when one is working *currente calamo* as he does.

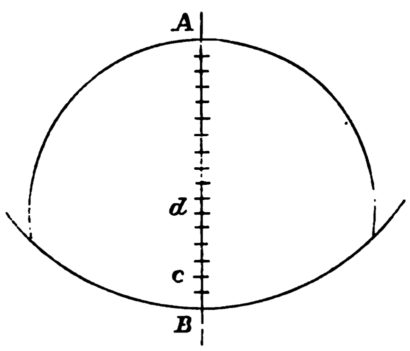
I send a diagram for Mr. Ratcliffe which he can have by applying to you, or which you can print if you think proper.



I may add, perhaps, that if the object be very close to the screen, we get the direct shadow also, so that we may have portions of three shadows on the screen at once. When "S. R." moved to the middle of the stream, of course this direct shadow fell on the water, and it is the reflection of this, as it were, that forms the reversed image on the bank. **Bow.**

THE EYE OF THE FLEA.

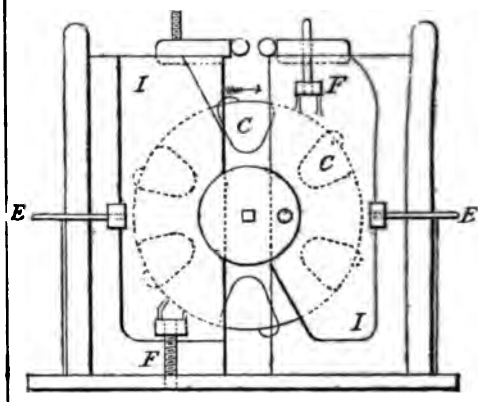
[21997.]—The poet has said, "The toad wears a precious jewel in its head." ("As You Like It," act 2, scene 1.) In whatever part of the head it may lie, and however beautiful when found, it cannot surpass, in lustre and beauty of setting, the eye of the domestic flea (*Pulex iritans*). When viewed under a power of 200 or 300 diameters by reflected light, it presents a crystalline lens about $\frac{1}{300}$ of an inch in diameter, surrounded by a dark brown or black rim, and sunk in a depression of the rich chitinous covering of the head. If the light be judiciously applied, this combination of bright light in the lens, with the middle tint of the surrounding yellow skeleton of the head and the dark supplied by the black rim—these being harmonised and blended by the shade and shadow of the depression, and assisted by the harmonious curve which bounds its dorsal margin—presents a combination worthy the study of the trained eye of the artist.

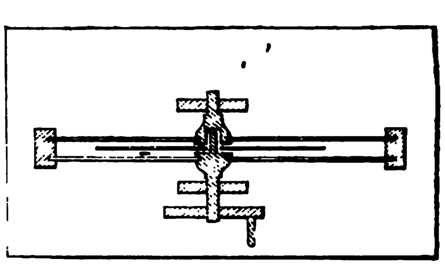


Its lenticular properties can be demonstrated by mounting the lens in balsam, and using it as an ordinary transparent object with the microscope—say, three yards in front of the room window in strong daylight—by attaching in the centre of one of the squares of glass some sharply-defined object—say, a Greek cross 3in. or 4in. big; then, with flat mirror and condenser, direct the image into the focus of the lens of the eye, and viewed with an objective of medium power, will show a very reduced image of the object on the window; or if by lamplight, with the microscope placed horizontally and the mounted lens on the stage, place a sharply-defined object—as a portrait on glass—about 3in. diameter and 10in. from the stage, with good lamplight condensed upon the picture by means of the bullseye. The light and picture being coincident with axis of tube, then with the achromatic condenser beneath the stage the image may be focussed with the lens of the eye, when, with a $\frac{2}{3}$in. or $\frac{1}{4}$in. objective, an image of the picture may be seen in miniature, demonstrating the eye to be lenticular; and by cutting sections of the lens, it is seen to be a double-convex, the curvature of the inner face being much quicker than the outer—the difference of the radii being about as 11 to 16. Thus, to produce a diagram of a section through the axis showing the relative proportion of the radii of the two surfaces, lay down a vertical line A B any convenient length to represent the desired thickness of lens, which divide into 17 equal parts; set off one part, B to C, making C the centre for the outer surface, as shown at A. Again, from B set off 11 parts as at *d*, and describe the curve B, which represents the inner surface. **T. P.**

VARLEY'S INDUCTION MACHINE.

[21998.]—I inclose elevation and ground-plan of a modification of Varley's induction electrical machine, arranged so as to avoid mechanical difficulties, and bring the construction within the reach of a schoolboy handy with his tools. A disc of ebonite, having on each face six carriers of tinfoil, rotates within two pairs of varnished glass plates, not more than $\frac{1}{2}$in. apart. The projections of the carriers rub against four brushes of metallic wire, two connected with earth by strips of tinfoil down the side supports, and two insulated, the lower on a strip of ebonite, the upper resting on the glass plates. The feeders F are in metallic connection with the tinfoil inductors, covering the middle of the outside of each glass plate. The cost of the ebonite disc may be avoided by using strips of glass, or ebonite penholders, to support the carrier.





Adelaide, S. Australia, Sept. 10. **T. D. S.**

A SHORT PAPER ON CARPENTRY.

[21999.]—I would like to supplement "O. J. L.'s" remarks on page 119 with a useful wrinkle or two. In the first place, I would not advise anyone to use any of the arrangements for holding tools to be ground upon a grindstone, because if so held they will be ground hollow, and their cutting edges will not stand long; whereas, by holding them in the hands they will be slightly rounded, which is the best form for maintaining the cutting edge. Then I would have two set-stones—one to be ground and kept perfectly flat, for plane irons, chisels, &c.; and the other for sharpening such things as sprig bits, drills, gouges, &c., which usually leave most workmen's set-stones in a disgracefully uneven state. Note that when a smoothing-plane or trying-plane iron is sharpened perfectly flat the corners should be slightly rounded off on the set-stone, or they will leave ribs on the work. But the most important omission that I find in "O. J. L.'s" directions is this: whenever a close-fitting joint is required the operator should have a good old knife, with the end ground off to an angle of 45°. A well-worn old ivory-handled one, cut short and ground up is best; then, with the square laid upon the work, draw this heavily and steadily from end to end perpendicularly; next, take a side cut at about an angle of 45°, knock out the cuttings, and then you have a fair field for your tenon saw, and the "best possible way of making a close joint." But remember that when you purchase a square (so-called), if you plane up carefully the edge of a board, and try it by scribing a line and then reversing, few squares as purchased will stand the test, and must be adjusted. Memo.: I would not use a smoothing-plane after a trying-plane, unless there were hollow places which I did not care to reduce the whole surface in order to get smooth and level with the long one.

Finally, my brethren, I find that wire nails are most useful, seldom needing any preliminary bradawl boring, and if wetted when driving, in a short time will hold on even to the loss of their heads.

A., Liverpool.

ELECTRIC ELEMENTS.

[22000.]—MR. SUTCLIFFE, in his last letter on this subject (21981), refers me to Mr. Crookes' experiments as proving that negative electricity is an active state, and that positive is not. All I can say is, authorities do not regard them as proving any such thing. They are simply considered as belonging to one of the few classes of experiments which prove that there is really a difference between the two states. They do not prove that one of these states must be negative and the other positive.

Moreover, if Ohm's laws *assume* for convenience that the passing of electricity through a conducting body is similar to the passing of heat, they do not prove it. And with regard to this point I should refer Mr. Sutcliffe to Maxwell's valuable "Mathematical Treatise on Electricity," where (Vol. I., p. 36), after mentioning certain experimental facts which prove that in some respects electricity obeys different laws to either heat or energy in general, he concludes:—"It is impossible, therefore, that electricity and energy should be quantities of the same category, for electricity is only one of the factors of energy, the other factor being "potential."

Voltameter.

ELECTRIC LAUNCHES.

[22001.]—I AM of Mr. Conry's opinion, that a good motor is a necessary element of success in electrical navigation; but I cannot agree with him that there are no such motors in the market. I have tested one which gave 85 per cent. on the Prony brake when driven by my battery.

I think that the principal cause of failure is that the battery so seldom suits the motor, nor does the propeller suit that or the boat; but where these are proportioned to each other, there will be no objections to either battery or motor. My own boat, 21ft. long, now being fitted up, is driven by my primary battery, and I hope shortly to give the results of the trial trip to the readers of "Ours" in full.

E. D. Goold.

[22002.]—MY reason for introducing this subject to your readers, and dragging Mr. Toynbee's letters into a wider publicity, was the belief that many owners of launches will be glad to give up the dirty and (pace the engineers) rather dangerous steam-engines. Launches used for pleasure purposes on the upper reaches of the Thames might with great advantage be driven by electric engines, and they would certainly be preferred by ladies. I am afraid that there is not much hope of the accumulator helping to solve the problem, for it must be remembered that it can only do so by having stations where the cells can be changed—no one would wait while his battery of accumulators was being charged—and the trouble and cost would be too much. Mr. Walker, I see, says it would be impossible to go from Sheerness to Oxford and back in an electrical launch worked by accumulators. I should be inclined to say that it is impossible to go even from London-bridge to Sheerness without exhausting any accumulator battery that a launch could carry. The nitric acid battery is, I suppose, unquestionably the best arrangement to use, and as to the fumes, I think there need be little difficulty, as the cells can be in a locker, which will discharge the fumes into the water. Mr. Sprague's table gives ·0981d. per equivolt as the cost of the nitric acid battery (an equivolt being 4,673 foot-pounds); but about twice that must be allowed, to make up for losses in the battery and the motor, the screw, however, being possibly not so wasteful as with the steam-engine. Perhaps our friend, "Sigma," will "transfer his thoughts" to this subject when he can spare time, and let a little light into it. At present I cannot see but that a primary battery would be very expensive.

Nun. Dor.

STEAM SQUIRT CONDENSER.

[22003.]—IF Mr. John Henderson (21916) will consider the matter, he will see that in order to make the squirt revolve by means of the escape of the steam, the orifices must be small to obtain the necessary velocity in the jets; this would entail back pressure on the piston, and retard the engine to a greater extent than the jets could possibly help it. The loss of friction in the pipes must also not be forgotten. What would practically take place would be, that the engine would drive the squirt through the medium of the bevel wheels, instead of the squirt assisting to drive the engine, and that in addition to this loss of power there would be the above-mentioned increase of back-pressure on the piston.

A. A. Myall.

BICYCLE MAKING.—I

[22004.]—BEFORE proceeding to describe the making of a bicycle, perhaps a short explanation of why I write these papers may not be out of place.

I am an amateur, and I write for amateurs; so if a tradesman should happen to read these papers, and should see anything described that would not be practical in a regular business shop, I hope he will not laugh, but remember this disclaimer. My methods are the results of personal experience, as I have made six machines of different patterns for myself and friends, on one of which a friend to whom I presented it won over £60 worth of prizes, one of which was worth £15, and none less than £5, and preferred it to one he had costing £22.

I cannot help noticing the reluctance makers seem to evince to giving any information through these columns on the *modes of manufacture* in answer to queries, although quite ready to avail themselves of the Editor's kindness to give publicity to improvements, &c., in new machines. I have no sympathy with this sort of trade secretism, and always do my best to defeat it wherever I meet it. Now having given my reasons, and had my grumble, I will proceed to business.

It is necessary, to make a bicycle, to have the following tools:—A lathe of 3 to 4in. centre, a vice to take about 3in., the heavier the better. Of course, the lathe must be capable of turning iron, the mandrel of which should go through the entire head and project beyond collar at back, and the poppet on back head centre should be driven by a screw for drilling a firm bench and something rather heavy to hammer on; also, a pair of large hand bellows if the amateur does not possess a forge. Perhaps some may laugh at the idea of using a hand bellows in bicycle making; but let me tell them, before I made my portable forge, I found a pair of 15in. and the kitchen fire a great assistance (no pun intended). The hand tools and some special tools (to make which I will give directions) I shall mention as we come to them.

The thing to consider now is where to get the parts, and to one who has not got a bicycle to refer to, what parts are required. The latter is easier to answer than the former; but I would strongly advise the intending maker to have nothing to do with small local manufacturers, for they will charge 40 per cent. more than he can get the same goods from the wholesale firms, carriage included; and if he complains, pitch up some good tale or other about carriage, freight, superior goods, makers mentioned being trash, &c. Now all this is humbug, as none of these men make their own parts, or but few of them, and those the amateur can make himself. Perhaps, as the firm I am about to mention advertises in "ours," I may be allowed to name the one I bought most of my parts of, that is Hughes and Co., Temple-street, Wolverhampton. I merely mention them because they served me and I had no fault to find; but, doubtless, there are others as good, but in finding them one runs the risk of falling over one of the queer sort. I have no interest in advising this firm, as I doubt if they would even allow me to go over their works and see the making of said parts. Before ordering, a list (priced) should be sent for.

I will now give a list of the parts necessary to buy to make a bicycle:—One ball Stanley head; if lathe will turn 1⅛in. diameter, buying rough will save cost, and I should advise so to do. I think this form of head is about the best, but, of course, others can use their opinion. One pair hollow-welded forks; these I strongly advise, they being more rigid, and so keeping bearings parallel—a point of importance when riding, also giving less to the strain between the handles and pedals, and so being less tiring to rider's arms.

One pair front bearings: now these may be simple or compound. Simple bearings are of several forms; but the most popular are the coned cotter, and also the "Wolverhampton" coned. Compound are of so many sorts it would take half the one number of the MECHANIC to describe them all, and would be outside my purpose. They may be classed under two heads, ball bearings and roller bearings, which latter are the older form. If the amateur wishes to have compound bearings, I should advise the "Æolus," a form of ball bearing. They run lighter than simple coned, and (which to my thinking, is of more importance) are nearly dust proof; but still coned bearings run nearly as light, and wear, with care, a long time. They do not cost nearly as much; in fact, may be made with hand-turning tools, the method of doing which I will presently describe.

One pair solid cranks. Now, in these there is a point much discussed. What is the best length for these? Now, if any one takes notice, he will find that most riders use the pedal at the lowest end of the crank. This would seem to indicate a long crank being the best; of course there is a limit to this. I have found a crank of 7in. fron outside end to end, with a slot to adjust pedal, is easiest to drive, as it does not need heavy treading nor lifting the leg too high.

Two pairs pedal plates. One set ribbed pedal rubbers. Three rough pedal centres. It is best to have more than required, as they are sometimes faulty, and it saves trouble and postage stamps.

Two rough coned pins, steel. I advise steel, as they wear longer and run lighter. Some may say, Why not make ball pedals? I reply, They are a lot of trouble to make, and are but very little lighter running, and if coned are made properly they are just as good.

Two outside pedal cones.

Nipples. Now the number of these will depend on size of machine intended to be made, the rule being in nipple wheels one spoke to the inch diameter of wheel. Say wheel is 52in., that would take 52 spokes, 26 on each side of hub. It is best to have a few more than are in wheel, as one or two may break in truing up wheel. In ordering state for front wheel; lock nuts to match.

Nipples for back wheels. Back wheels are made about 16in. diameter, and before-said rules apply here also; spokes to fit nipples. State length required, and see they fit nipples well, as this adds to rigidity. I have had them a little larger than nipple hole, and carefully made a bush bit exactly size of spoke and bored nipple to fit truly. I have mentioned, as I think, they are far more satisfactory than spokes screwed in to hub, or direct-action as they are called, and for these reasons (I speak from experience): In building wheel one cannot get as great a strain on spokes, so causes a loss of rigidity. If one breaks, it is a job to get piece left in hub out. Spokes made this way are more liable to break on account of their being weakened by cutting screw just where they are wanted to be strongest, and, lastly, they are more trouble to make.

One pair crescent rims. Mention size required. This shape holds the rubber tires better than the V-shape, and is a little lighter, the V being, as far I know, only used in cheap "Brumagem cast-iron sudden deaths."

One pair rubber tires to fit rims, and see they *do* fit, as if they do not they are always getting loose. If too large and if too small, a cut gapes open, so they should be a little smaller than the rim, but not much—say, an inch in loop, but in its own diameter. It should be as near as possible, but certainly not larger than section of rim.

Beam or back bone, with neck and forks brazed in. I say brazed, as I have seen several break off, when welded just at joint, which is most dangerous. This is through being burnt or over-heated in welding, and as brazing does not need so high a degree of heat there is no risk of this happening. The beam generally needs a little bending to fit properly after machine is together. This I will give directions for at the proper time. The larger the beam is, the better it looks. One spring-curled eye—rough, of course. Any pattern may be used that is fancied, but these I have found as good as needful.

One rough back hub. I strongly advise this in rough, and don't be put off with malleable cast, which is to be told from stamped iron by the marks of the sand on skin. I think iron is preferable to red metals, for this reason: the nipple hole threads stand the strain so much better, never stripping out—a fault red metal is prone to. Why I recommend this to be made is—one can depend that the holes are drilled at the proper angle to suit diameter of wheel, a matter of some importance, and also are sure the nipples fit well, and the threads are good in nipple holes, which is not always the case with shop-finished hubs. 1. Rough spoon brake. There are many kinds of brakes, but I don't know any much better, take it all round, than the spoon; back wheel brakes, for many reasons, are not to be advised. I strongly advise all riders against riding without a brake, as dangerous to themselves and others. Some bicyclists I have known have made it a boast "their legs were *their* brake." This is folly, as a moment's thought will show anyone can go much farther with the same exertion, as the rest to the legs going down hill gives strength to go faster up the next, and if a man has but a limited time to ride, and wants to get as much exertion in it as possible, why he is not obliged to use his brake because he has one. I may mention, by the way, the remark I heard a man make who was himself one of the longest-distance riders of the world: "I hate to get into a piece of road that is one long level stretch, as I always get more tired there than where there is here and there a hill. I suppose using the brake the other side rests one somewhat."

If back-wheel hub is to be made with cones, two cones will be required. One of these should not be tapped, and do not order coned pin, for reasons to be explained further on.

1lb. rubber cement to put on tires; one pair handles—the sort I must leave to taste.

Bell, lamp, or alarm and oil-can, I must leave to buyer's consideration, merely making this remark: these things are cheaper at wholesale houses, and I have found Harrison's double alarm, and the King of the Road lamp very good. 1 saddle. Now of all I have seen or used, I think none come up to the simple suspension, as it does not gall one's sit-upon, a bad fault with most others. I do not advise the so-called ventilated or webbed-seated suspension, as cutting the iron plate for webbing weakens the saddle just where it wants to be strongest, and the ventilation gained is—Ahem.

I have omitted, purposely, a front-wheel hub, as I think this is better made by a smith on a plan I shall presently describe, the object being to get iron flanges with a *tool* steel centre-pin or axle, the advantages of which I will give; also handle bars, as these are best hand-hammered by a smith under direction. **Ixion.**

REFLECTION OF LIGHT.

[22005.]—Professor Tyndall is, of course, strictly correct when he says that the light falling upon a body is divided into *two* portions. What "L. S." (letter 21976) calls regular reflection and surface scattering in all directions, are merely different degrees of the same thing. Each case is one of true reflection in which the law of sines holds.

Surface-scattering is due to irregularities of surface, which cause the incident light to fall at every angle, and consequently to be reflected in every direction.

Partial absorption and re-emission is an entirely different thing, and it is this entirely that gives to bodies their colour. In the quoted case of the moon, if she were covered with the blackest velvet, she would actually appear *whiter* than she does now, because, in the case of black velvet, very little if any light is re-emitted after being absorbed, and the light that we receive from it is almost all reflected light, which is the same colour as the incident light.

"L. S." will remember that black really means absence of colour. If the moon were covered with red flannel, she would certainly appear red, since here would be a clear case of absorption and re-emission. **Nabla.**

LIFE AND MATTER.

[22006.]—"E. F. H.," in letter 21961, disjoints two sentences of my letter 21934, and is then astonished at my calm assumption of knowledge. If "E. F. H." intends to criticise, I must ask him to do so in a fair way. My letter was written to Mr. Grey, who, as I take it from his writings, does not admit of the existence of any other forces or conditions of matter than those we can produce and control in the chemical laboratory. It was to avoid the trite repetitions of arguments purely physical that the above sentences were written. I do not assume knowledge. My letter was written against such assumption, and as "E. F. H." is not slow in placing himself within the ranks of scientific men, it is only proper that he should act like one, and judge my letter on its whole merit. "E. F. H." calls the amœba an animal, because it inhales oxygen and exhales carbonic dioxide. As a chemist and physiologist, "E. F. H." knows, no doubt, that all fungi inhale O and exhale CO_2, which is quite in conformity with the part they play in Nature's laboratory as disintegrators of dead organic matter. But I doubt if "E. F. H." would call a fungus an animal. **Anglo-Dane.**

MATTER AND THOUGHT—MESMERIC TRANCES.

[22007.]—I may now put a further question to "F.R.A.S." in reference to what he has himself seen (21953, p. 171). Can he imagine "a lad" holding out "a pretty heavy chair at arm's length" for a considerable time without manifesting distress or *exhibiting in his attitudes the muscular tension* necessary to the result? Now that is just what occurs, as "F.R.A.S." will no doubt remember if he can fully recall the circumstances. The body is simply placed in an attitude to avoid falling, and then retains the weight much as a statue would. In what way is it conceivable that such a phenomenon could be partly the result of training and partly subjective? The most trained athletes show by their strained and quivering muscles and the expression of their faces the strain they are put to in such cases. But I have seen people doing this very thing and calmly singing a song at the same time. These suggestions are really more incomprehensible than the truth of the circumstances.

In reply to "F. W. H.," 21960, p. 175, I cannot support or accept his electrical analogies. In reply *to his question, mere matter* does certainly *not* produce a force when I set up a galvanic battery, so I do not call such a force "an entity working with the elements." The battery simply directs pre-existing forces, and re-distributes energy; like the steam-engine, it *produces* nothing. A piece of wire does *not* reproduce the human voice 1,000 miles away; the voice sets up molecular vibrations or motions in the wire, which produce magnetic changes, and these again set up undulations in the air which are similar in character to those produced by the first voice.

I can assent to what he says of the action of "living brain," while thus denying its analogy to a galvanic battery; but then he means his living brain, the mere matter and energy, and I mean by it these *plus* "life." He says, "I understand electricity." I say I do not; I know something of some of the effects we attribute to that agent or action, and my knowledge leads me to receive with much doubt the statements of physiologists; especially, I doubt Büchner's statement that "Electric currents surround the nerves when at rest," and diminish when the nerve is excited. I believe less and less in the electrical actions in living bodies, except as merely local *consequences* and attendants of the chemical and mechanical actions going on. All the parts are fairly good conductors, and I do not see how efficient or work-performing currents are to be transmitted. I am inclined to believe that the vital electric actions are purely *local*, and that the currents obtained in experiments are actually called into existence by the conditions of the experiments themselves. Nerves do conduct some action, and I do not believe they *generate* a force, as Büchner says; the brain is the generator, and also those sub-brains, the nervous ganglia; but the pure nerves appear to be connections rather than sources. But that is a subject I do not mean to be led away into discussing.

"W. A. L." (21962, p. 173), speaks of the difference in the validity of my arguments in the early part of this discussion, and this latter part, and appears to think that is a discovery. What would he have of me? He says, at first, "I dealt only with facts, and held opinions as utterly valueless." Of course I did. I was then dealing with a question of mere fact: Did mind act on mind independent of the organs of sense? Mere *à priori* opinions as to the probability of this were utterly valueless in presence of evidence of the actual occurrence. The only thing to do was to examine the evidence, and as I knew absolutely the facts, of course I could speak decisively. But now we are not in the domain of facts, but of the causes of the facts—the nature of the agents. *We have only opinions to discuss*, and deductions to draw from very limited knowledge.

True, I did define science as "what is to be *known*," and as we have now to deal not with knowledge, but with beliefs and opinions, of course I treat them very differently from facts. I have not spoken of the "extra-material principle as a truth and a fact." On the pages referred to I find that I said, "I carefully left open the question whether there is in man an inner spiritual agent distinct from the material organs," and further on, "No man knows what the nervous agent is." What I did say was that "facts strongly support *the belief* in an agent distinct from the bodily organs though operating through them." Furthermore, notwithstanding the reference to my stating it is "a fact," p. 66, there is no word of the kind there. All that I said about facts was to protest against the making of mere opinions of Moleschott and Büchner into *facts*, and then setting up these pretended facts as reasons against examining the *real facts* of thought transfer. What I have said is that, *assuming the existence of the extra-material essence*, it must needs be out of the range of science, which is limited to matter and energy—to physics, but by its nature belongs to the province of *thought and belief*, to metaphysics as distinguished from physics.

I do not like going over my past writings and contradicting false deductions; but it is inevitable in such widespread discussions, and if I allowed to pass the inductions of "W. A. L.," in which he tries to make me say things I do not say, and then winds up by putting me among those who "talk about what they know nothing about, and assert as a fact what is nothing but a notion," someone else would proclaim directly that he had proved this, and I could not deny it.

It is impossible to write in armour and test each word as if it were a poison one was tracing; so once for all let me say that whatever particular words may be tortured into, that, as I have said "no man knows," so I do not pretend to *know* anything about the nature of life and thought; but I consider that, taking into account the opinions of the wisest of men through all the ages, and the actual evidence which is attainable, I feel justified in the *belief* in an entity distinct from matter capable of separate existence, but acting in a material world only through matter; that entity, as the cause or agent of life and thought, I call "spirit" without the smallest pretence to understanding its nature. Furthermore, I think that "to hold an *opinion* about what is unknown and unknowable is (not) ridiculous," but to assert a *knowledge* is so. We hold opinions about very many things that we see either in themselves or in their effects, but of the actual nature of which we know nothing. If we entertained thoughts and opinions only about what we *know*, we should not take much mental exercise.

As to Mr. Morrison's interesting case of prolonged sleep (21966, p. 174,) I do not quite understand what he wishes to impress on us. But I do know this much, that had the patient been a nun in a Spanish or Belgian convent she would have become an "ecstatic," have seen and talked to the Virgin Mary or some saint, very likely have been marked with the "stigmata" and possible taken to bleeding at the marks on Friday. What I do not understand is the distinction between "*natural* trance, usually called *deep mesmeric sleep*." We all know (that is, all sensible mesmerists) that the mesmeric sleep is nothing supernatural—it is a natural state which often occurs spontaneously, and which can be brought about by the external mental influence; in the natural trance, and still more in the artificial one, phenomena are witnessed, powers exercised greatly different from the ordinary ones, and these indicate a mode of perception independent of the usual bodily organs of the senses. I have a very strong conviction that a powerful mesmerist would easily arouse the patient out of that sleep.

I know what has occurred to myself, and I think I have mentioned it before in these pages. I was living in lodgings in a small country town, and coming home to dinner in the evening I found the house in commotion, and that the servant was lying like a corpse on the kitchen hearthrug. She had been there for hours, and doctors had vainly tried to do anything with her; in fact she was in a regular cataleptic trance. I went down, took hold of her hands, looked at her a few minutes, and then said "Get up." Five minutes after she was laying my table for dinner. Of course, it was nothing but *imagination* on her part! **Sigma.**

CONCERNING A HYACINTH BULB.

[22008.]—I am well aware that there is not an exact parallel between the attribute of sweetness in sugar and the phenomena of life in a hyacinth bulb. The point I wished to establish was that, as we cannot *explain* the simple attribute of sweetness in terms of the formula of sugar, any more than we can explain the phenomena of life, we are not acting logically in assuming an extra-material principle in the latter case, and not in the former. If we cannot explain the simpler case, "sweetness," much less is it likely that we can elucidate the more complex case "life"; but "Sigma," and the school to which he belongs, and which he has so ably represented in this discussion, quite admit that sweetness is an attribute of $C_{12}H_{22}O_{11}$, although they cannot explain how; while, when the phenomena of life are in question, they at once assert that matter cannot possibly give rise thereto, and invent an extra-material principle to account (?) for the same. This is treating the two cases differently without due grounds, and, moreover, if by belief in the said principle the phenomena of life were really explained, or even rendered more comprehensible, there would be good argument for its existence; but the assumed principle does not in reality explain anything; nay, it only makes the mystery of the bulb yet more mysterious. We know, dimly and darkly it may be, but still we know the wonderful things matter can do. We see four elements forming almost countless compounds; we study the structure of these, and notice that a difference in arrangement of atoms in a molecule produces the greatest differences in physical attributes and chemical properties. Take, for instance, the fragrant acetate of ethyl, and the intolerably nauseous butyric acid. (I might fill a column with similar examples.) All this we know happens, but its explanation in terms of matter eludes us, and it is, I maintain, illogical and unscientific in the highest degree to limit arbitrarily the powers and forces of which we know so little. Of course all this implies a change in our conception of matter, and such change is in progress; only very ignorant persons speak contemptuously of "mere matter" now; our views are broadening, and as our knowledge grows, we are learning to regard as wonderful beyond our powers of expression "the mysterious thing called matter." "Sigma" will, perhaps, pardon me for saying frankly that I do not consider the opinions of "all the sages of past time" worthy of the slightest regard in relation to a question of modern science. It may fairly be conceded that in artistic work, in painting and music, the old masters were our superiors. No modern paintings have the charm of the old ones; and all our modern musicians rolled into one could not write the works which have rendered Mozart, Beethoven, and Handel immortal. But as far as science is concerned, the very reverse is the case; and this "Sigma" knows as well as I do. The "Sages" (capital letter, please), thought that Nature abhorred a vacuum; that the earth was the fixed centre of the universe; that a ten-pound weight fell ten times as fast as a one-pound weight;

that there were four elements; that combustion was due to phlogiston; that a magnet had a soul. Does "Sigma" believe all this? and if not, why does he quote the "Sages"? The mere opinion of such men as Haeckel and Büchner, on such a subject as the nature of life, is of more importance than all the ideas of the "Sages." "Sigma" says "nothing is more certain than the break of continuity in nature where life is superadded to matter"; I demur, and think any theorem in Euclid is much more certain. There are very few distinct lines of demarcation in nature, and it is not at all certain that one exists here. I also think it *is* unreasonable to assume that life appeared on the earth a new agent, "not matter, nor actions of matter, but operating on matter"; and call on "Sigma" for proof.

The astonishment of "Anglo-Dane" on reading my last letter can only be explained on the assumption that he knows nothing of recent views in natural science, and this explanation is strengthened by reading the remainder of his letter. He says he "is fully aware of what forces are in operation during the growth of a cell." Perhaps he will be kind enough to send us an account of the said forces; and we may be able to obtain the differential equations of the dynamics of a cell. We would probably not be able to integrate them; but I am sure our mathematical correspondents would like to try. My statement that life is apparently volatile, was not meant as a joke. If you boil a hyacinth-bulb it loses life, and if life be an extra-material principle, it is evidently volatile at 100° C. It is also volatile at zero. In conclusion, I do not expect to change "Sigma's" views, and he will scarcely succeed in his endeavour to drag me backwards to the scientific opinions of our grandmothers; but I hope the discussion may cause our readers to ponder over the great problems involved; and to look more thoughtfully at the hyacinths they will see during winter and spring.

Elswick Science School. **Wm. John Grey.**

SIZES OF BRIGHT ROUND STEEL WIRE IN FOOT LENGTHS.

[22009.]—In the watch and clockmakers' tool dealers' lists, bright round steel wire, in foot lengths, under Stub's wire gauge numbers, at various prices per lb.; thus, all sizes to No. 15 are 2s. per lb.; 69 to 70, are 11s. per lb.

It would be very useful to amateurs and others who live at a distance to have a tabular statement of the weight in grains of each one-foot length from the largest to the smallest size. I presume the sizes range from 1 to 70 of the small gauge, and from A to Z of the letter, or large gauge.
